F. **Description of Disposal Method**. Methods of placement and disposal for these projects will utilize a variety of dredges including hydraulic cutterhead, hopper, and mechanical, deep draft, scow, and various shallow draft barges. In addition, track hoes, bulldozers, dump trucks, backhoes, marsh buggies, and other similar earthmoving construction equipment will be utilized dependent on the scope of each project.

II. **Factual Determinations (Section 230.11)**:

A. **Physical Substrate Determinations**.

(1) **Substrate Elevation and Slope**. The barrier islands restoration project would consist of beach/dune restoration projects and would be designed to sustain elevations and slopes consistent with similar habitat types in the vicinity that has been sustained under the typical energy climate. Potential marsh and coastal maritime forest restoration components on the barrier islands will also be further evaluated in accordance with and conformity with the Organic Act, National Park Service (NPS) mission, and NPS management policies. The beach could be constructed to between approximately 0 to 2-foot elevation with a 1:10 slope on the foreshore. Dune elevations along the mainland could be constructed to a maximum height of 6 feet with 1:3 slope. Marsh habitat would be constructed between -0.5 and 2-foot while the scrub/shrub would be constructed to between approximately 4 to 6 feet. The ring levee around Forest Heights would be constructed up to a 12- or 16-foot elevation. The ecosystem restoration projects would be constructed at the appropriate elevations to ensure hydrology at the site. The SAV restoration project would be constructed at about -5 to -10 feet water depth.

(2) **Sediment Type**. Materials used for the beach restoration actions will consist of fine to medium grained sand that is compatible (grain size, color, and texture) with existing beach sediments. Sandy material with a small silty component will be used where sediment is required for marsh restoration. Materials dredged from drainage channels and canals will likely contain soft, fine-grained, organic silts and clays with some fraction of sand. This material will be disposed in approved upland sites.

(3) **Dredged/Fill Material Movement**. Fill material would be pumped or trucked directly onto the beach sites. It is expected that a readjustment phase will occur and sand materials redistributed to form a more natural profile. Restoration areas will utilize material that may contain a higher percentage of fine grained materials. Silt fences/curtains and other best management plans (BMPs) will be utilized to reduce material movement during heavy equipment operations. It is believed that no adverse impacts would occur from movement of materials.

Physical Effects on Benthos. No impacts to benthos are anticipated in the upland areas. There would be temporary disruption of the aquatic community as a result of the proposed projects being constructed. Areas where sand and sediments are laid directly upon the bottom open-water habitat to create marsh or restore barrier islands and/or beaches may result in destruction of sessile benthic fauna. Non-motile benthic fauna within the project sites would be lost as a result of the organisms not being able to penetrate through the thick layer of material that will be used to construct the tidal marsh and sand placement for restoration. This loss of sessile benthic fauna would be minor due to the tidal marsh area and other restoration area sites encompassing only a small percentage of the entire Mississippi Sound. Benthic fauna, such as crabs, are anticipated to re-colonize the area upon restoration and in addition, should provide aquatic habitat for various motile and non-motile benthic fauna. The intertidal zone and sub-tidal zones along the restored beaches should provide rapid recovery of and recruitment of benthos. The marsh would provide additional nursery area along the outer fringes suitable for fishes following the proposed activities. Non-motile benthic fauna within the project area may be destroyed by the proposed operations, but should repopulate within several months after construction activities are completed.

Physical Effects on Wetlands. Restoration projects would restore damaged and filled wetlands providing an overall benefit to wetlands. Implementation of the proposed levee at Forest Heights would not require fill in wetlands. It is anticipated that relocation of city facilities in Moss Point and homeowner assistance relocations would be located in uplands and any required fill material would be obtained from upland sources.

(4) **Other effects**. No other effects are anticipated.

(5) **Actions Taken to Minimize Impacts (Subpart H)**. Actions will be taken to minimize impacts to all project areas during the construction activities. BMPs and/or silt curtains will be used at the construction sites, where applicable, to minimize turbidity and curtail material migration. Borrow material used in construction will be utilized in such a manner to minimize impacts to surrounding areas.

B. **Water Column Determinations**.

(1) **Salinity**. Projects that are being tentatively selected for construction should have minimal impacts to salinity as a result of its implementation. In fact, the filling of Ship Island breach is anticipated to have a positive benefit to salinity in Mississippi Sound.

(2) **Water Chemistry (pH, etc.)**. All sediment and material used in the construction of the identified projects will be clean materials removed from sources of contamination and considered contaminant free. Such material will have no effect on surrounding water chemistry.

(3) **Clarity**. Construction activities in association with beach nourishment and dune construction and tidal marshes will reduce water clarity due to elevated suspended sediments in the water column; however, BMPs and/or silt curtains will be used, where applicable, to minimize impacts to the project area. Minor increases in turbidity may be experienced in the immediate vicinity of the project areas during construction operations. However, these increases will be temporary and would return to pre-project conditions shortly after completion. In fact, several components of the proposed project may improve water clarity because particles tend to settle out of the water column at tidal marsh areas.

(4) **Color**. No effect.

(5) **Odor**. No effect.

(6) **Taste**. No effect

(7) **Dissolved Gas Levels**. Temporary decreases in dissolved oxygen will likely result from some of the construction activities, but this will only be of a short duration. The construction activities and the return water are not anticipated to adversely impact dissolved gas levels.

(8) **Nutrients**. Slight increases in nutrient concentrations may occur from the proposed construction activities; however, these concentrations would be rapidly dispersed. These described increases would have no significant effect to the water column. Further studies prior to construction and implementation of certain measures would be conducted to determine possible impacts.

(9) **Eutrophication**. The projects tentatively selected for construction would have minimal impacts to eutrophication effects.

C. **Water Circulation, Fluctuation, and Salinity Gradient Determinations**:

(1) **Current Patterns and Circulation**.

(a) **Current Patterns and Flow**. Restoration of the barrier islands would be modeled to determine effects of filling the breach between East and West Ship Islands, creating a feeder source of sand to supplement littoral drift and migration, and filling of water bottoms in order for expansion of the island footprints. The subsequent return water flow is also not anticipated to affect current

patterns and flow in the vicinity of the mainland. The environmental restoration sites would restore historic water flow patterns. Levee construction would likely divert water away from the urbanized areas. The non-structural plan would also help restore historic water flow patterns by removing structures all together or raising them from their base elevation.

(b) **Velocity**. No Effect.

(2) **Stratification**. No Effect.

(3) **Hydrologic Regime**. Environmental restoration would result in a benefit to the hydrologic regime as the lost hydrology is restored to historical wetlands.

(4) **Normal Water Level Fluctuations**. No Effect.

(5) **Salinity Gradient**. Salinity in Mississippi Sound is highly variable due to the inflow of freshwater from surrounding rivers and the tidal influence from the Gulf of Mexico. Restoration of barrier islands would affect salinity gradient and further analysis would be conducted to determine the effects of these measures.

D. **Suspended Particulate/Turbidity Determination**:

(1) **Expected Changes in Suspended Particulates and Turbidity Levels in Vicinity of Placement Site**. The placement of fill material at the proposed project sites within Mississippi Sound and within the vicinity of the barrier islands would reduce light penetration through the water column, thereby reducing photosynthesis and surface water temperatures. Although it is expected an initial high volume loss of sand from the restoration projects at the barrier islands would occur, it is expected that sand movement would decrease once equilibrium is naturally achieved. These conditions could potentially alter visual predator-prey relations in the immediate project vicinity. In addition, sediment adheres to fish gills, resulting in respiratory stresses, and natural movement of eggs and larvae could be potentially altered as a result of the sediment adherence. These are minor, short-term impacts due to the short duration of construction activities. It is expected that distinct bars would develop nearshore by the nature of the waves and depths within the project vicinity and could potentially result in a seaward expansion.

Construction of the levee around Forest Heights, and environmental restoration sites could cause sediment movement and isolated increased turbidity around the construction sites. Changes in substrate are not expected nor will any deleterious materials be added to the sediment during construction activities.

(2) **Effects on Chemical and Physical Properties of the Water Column**.

(a) **Light Penetration**. Light penetration through the water column at the proposed sites may be temporarily affected but is anticipated to return to previous conditions upon completion of construction activities.

(b) **Dissolved Oxygen**. Future studies would be conducted prior to construction and implementation of certain measures to determine impacts within the bays and Mississippi Sound.

(c) **Toxic Metals and Organics**. Sites have been picked to avoid any potential toxic metals and organics.

(d) **Pathogens**. No effect.

(e) **Esthetics**. Esthetics would be reduced within construction areas, due to the physical presence of the heavy equipment used in the construction process; however, these impacts would be temporary and insignificant. Once the construction is complete, the esthetic values provided by barrier island restoration, a restored beach-dune system, and environmental restoration of wetlands would have many beneficial impacts. Construction of the projects would actually result in an improvement to aesthetic quality as coastal Mississippi was devastated as a result of Hurricane Katrina. No adverse impacts are anticipated from the ring levee around Forest Heights and the non-structural plan.

(3) **Effects on Biota**. The proposed beach and ecosystem restoration projects are designed to enhance the barrier island ecosystems. These actions would increase valuable habitat resulting in an overall improvement and continued health of the local wildlife. No adverse impacts are anticipated from the ring levee around Forest Heights and the non-structural plan due to its existing urbanization.

(a) **Primary Production Photosynthesis**. No impacts to primary production photosynthesis are anticipated.

(b) **Suspension/Filter Feeders**. It is anticipated a temporary impact to suspension/filter feeders would occur as a result of the construction activities; however, no long-term impacts are anticipated.

(c) **Sight Feeders**. Shorebirds tend to be attracted to established beach/dune systems. Construction activities (i.e. dredging and subsequent placement to restore the barrier islands) are sometimes attractive sites to many sight feeders due to the presence of food items in the material. Impact of these activities along uplands, beaches, and ecosystem restoration sites on sight feeders is expected to be a beneficial, short-term effect. No adverse impacts are anticipated to occur to sight feeders as they would avoid construction areas.

(4) **Actions Taken to Minimize Impacts (Subpart H)**. BMPs would be incorporated into project designs and specifications during project development.

E. **Contaminant Determinations**. Materials used in the construction of the proposed measures would consist of marine and/or river sand and sediments from sources removed from contamination. Previous construction activities and water quality certifications of these type projects in this region has found that the materials are free of contaminants.

F. **Aquatic Ecosystem and Organism Determinations**.

(1) **Effects on Plankton**. It is anticipated a temporary impact to plankton would occur as a result of the construction activities; however, no long-term impacts are anticipated.

(2) **Effects on Benthos**. Temporary disruption of the aquatic community is anticipated at the beach, dune, and marsh restoration sites. Non-motile benthos at areas where materials will directly covering water bottom would be destroyed. Non-motile benthic fauna within these areas will be lost as a result of the organisms not being able to penetrate through the thick layer of fill material that will be used to construct the tidal marsh and beaches. This loss would be minor due to the project areas encompassing only a small percentage of the entire Mississippi Sound (approximately 750,000 acres). Benthic fauna, such as crabs, are anticipated to rapidly re-colonize these areas upon construction completion. Non-motile benthic fauna within other construction areas may be destroyed by the proposed operations, but should repopulated within several months after completion. Motile benthic and pelagic fauna, such as crabs, shrimp, and fishes, are able to avoid the disturbed area

and should return shortly after the activity is completed. Larval and juvenile stages of these forms may not be able to avoid the activity due to limited mobility. Construction activities at the proposed sites are anticipated to have no significant effects to the benthos.

(3) **Effects on Nekton**. No Effect.

(4) **Effects on Aquatic Food Web**. No Effect.

(5) **Effects on Special Aquatic Sites**. No Effect.

(a) **Sanctuaries and Refuges**. The measures have been developed in such a way as to avoid direct impacts to sanctuaries and refuges. The Sandhill Crane Wildlife Refuge and the Grand Bay National Estuarine and Research Reserve are both located in Jackson County. Numerous measures, particularly ecosystem restoration sites, would provide additional wetland functions nearby existing refuges.

(b) **Wetlands**. The ecosystem restoration sites would result in numerous acres of wetland restoration which would provide numerous positive benefits. Under the current Forrest Heights 21-foot levee alignment alternative, there is an expected loss of 3.6 acres of wetland vegetation impacted by construction of the levee. Although native vegetation under the levee footprint would be lost, the levee itself would be vegetated with non-native species for stabilization of the structure. The compensatory mitigation would be incorporated in the project plan development phase.

(c) **Mud Flats**. No Effect.

(d) **Vegetated Shallows**. The measures have been developed in such a way as to avoid vegetated shallows directly; however, the indirect and cumulative effects are unknown and further studies would need to be conducted to determine the full level of impacts prior to project development and construction.

(e) **Coral Reefs**. Not applicable.

(f) **Riffle and Pool Complexes**. The measures have been developed in such a way as to avoid direct impacts.

(6) **Effects on Threatened and Endangered Species**. The Corps, Mobile District is currently coordinating with the U.S. Fish and Wildlife Service and the National Oceanic and Atmospheric Administration Fisheries concerning the proposed MsCIP Comprehensive Report and Programmatic EIS impacts to any threatened and endangered species. Protective measures will be implemented in order to reduce impacts to listed species.

(7) **Effects on Other Wildlife**. Hurricane Katrina and the associated storm surge resulted in numerous adverse impacts to existing wildlife and wildlife habitat. The proposed projects should enhance overall wildlife and associated habitats. Construction activities may result in temporary impacts to existing vegetation in the immediate areas; however it is expected all impacts would be short-term and minor, and in some cases discountable. Urbanization of rural lands could occur and cumulative impacts of this relocation would need to be evaluated to determine the full level of impacts to wildlife habitat.

(8) **Actions to Minimize Impacts**. BMPs would be incorporated into project designs and specifications during project development. Further studies would be conducted prior to implementation of certain measures and prior to specific project development.

G. **Proposed Disposal Site Determinations**:

(1) **Mixing Zone Determination**. The State of Mississippi will specify a mixing zone not to exceed ambient turbidity by more than 50 nephelometric turbidity units at the outer limits of 750 feet for turbidity compliance. Turbidity from material placed in or near the water is anticipated to quickly settle out of the water column. Thus, not exceeding the proposed water quality criteria issued. No adverse impacts are anticipated from construction sites located at upland sites. Thus, no mixing violations are expected.

(a) **Depth of water at the disposal site**. Placement of material associated with beach and marsh restorations will be along the shoreline or nearshore waters.

(b) **Current velocity, direction, and variability at disposal sites**. Further studies would be conducted to determine the impacts in conjunction with implementation of certain measures, such as restoration of Ship Island and placement of sand into the littoral zone around other barrier islands.

(c) **Degree of turbulence**. No impacts are anticipated.

(d) **Stratification attributable to causes such as obstructions, salinity or density profiles at the disposal site**. No impacts are anticipated.

(e) **Discharge vessel speed and direction, if appropriate**. Further studies during project development would determine impacts.

(f) **Rate of discharge**. Rate of discharge will vary according to the particular type of equipment placing materials.

(g) **Ambient concentrations of constituents of interest**. Not applicable.

(h) **Dredged material characteristics, particularly concentrations of constituents, amount of material, type of material (sand, silt, clay, etc.) and settling velocities**. Materials used for the beach restoration actions will consist of fine to medium grained sand that is compatible with existing beach sediments. Sandy material with a small silty component will be used where sediment is required for marsh restoration. Sandy clay fill material would be used to construct the levee around Forest Heights.

(i) **Number of discharge actions per unit of time**. The number of discharge actions per unit of time will vary depending upon particular project activity.

(2) **Determination of Compliance with Applicable Water Quality Standards**. Coordination will be conducted with the appropriate regulating agencies to ensure compliance with all applicable water quality standards.

(3) **Potential Effects on Human Use Characteristics**.

(a) **Municipal and Private Water Supply**. It is anticipated implementation of any measures would have no effect.

(b) **Recreational and Commercial Fisheries**. Recreational and commercial fishing would be temporarily impacted primarily as a result of the physical presence of heavy equipment during operation activities. Limited navigation would occur at the offshore borrow sites.

(c) **Water Related Recreation**. Water related recreation would be temporarily reduced in the immediate vicinity of project sites during construction.

(d) **Esthetics**. Esthetics will be temporarily reduced in the immediate vicinity of the proposed project sites. Many recreational vessels utilize Mississippi Sound within the project vicinities and it is believed some residents and visitors may be disturbed by the presence of the heavy equipment during construction. However, construction activities are temporary in nature so the disturbance is anticipated to be minimal. Furthermore, upon project completion, the restoration projects should provide residents and visitors with a more esthetically pleasing view. The proposed marsh creation and beach restoration projects would provide additional habitat to numerous marine birds.

(e) **Parks, National and Historical Monuments, National Seashores, Wilderness Areas, Research Sites, and Similar Preserves**. Further studies and coordination with resource agencies would need to be conducted to determine the full level of impacts of certain measures. Gulf Island National Seashore, administered by the National Park Service, including Petit Bois, Horn, East Ship, West Ship, and a portion of Cat Island are included within the scope of the restoration plan. The National Park Service is currently providing input regarding the feasibility of restoration involving the barrier islands in compliance with existing agency programs, management policies, and enabling legislation. Petis Bois and Horn Islands are also congressionally designated wilderness areas.

(f) **Other Effects**. No effect.

H. **Determination of Cumulative Effects on the Aquatic Ecosystem**. Further studies would need to be conducted to determine the cumulative impacts of certain measures.

I. **Determination of Secondary Effects of the Aquatic Ecosystem**. Further studies would need to be conducted to determine the cumulative impacts of certain measures.

III. **Finding of Compliance With the Restrictions on Discharge**.

A. No significant adaptations of the Section 404(b)(1) guidelines were made relative to this evaluation.

B. Further studies would need to be conducted to determine that any proposed project in conjunction with implementation of certain measures would represent the least environmentally damaging practicable alternative.

C. The planned construction activities and placement of dredged materials would not violate any applicable State water quality standards; nor will it violate the Toxic Effluent Standard of Section 307 of the Clean Water Act (CWA). Appropriate evaluation of analytical and ecotoxicological testing of sediments, site water, and elutriates results would reveal if any adverse impacts would result from the proposed disposal actions.

D. It is believed that use of the proposed disposal sites will not jeopardize the continued existence of any Federally-listed endangered or threatened species or their critical habitat.

E. It is anticipated construction of the proposed projects and placement of dredged material would not contribute to significant degradation of waters of the United States or result in significant adverse effects on human health and welfare, including municipal and private water supplies; recreation and commercial fishing; life stages of organisms dependent upon the aquatic ecosystem; ecosystem diversity, productivity and stability; or recreational, aesthetic or economic values.

F. Appropriate and practicable steps would be taken to minimize potential adverse impacts of the discharge on the aquatic ecosystem.

District Engineer

3.2 Coastal Zone Management Program Federal Consistency Determination

The National Coastal Zone Management (CZM) Program is a voluntary partnership between the Federal government and United States (U.S.) coastal states and territories authorized by the Coastal Zone Management Act (CZMA) of 1972. The Coastal Programs Division, within the National Oceanic and Atmospheric Administration's (NOAA), Office of Ocean and Coastal Resource Management, administers the program at the Federal level and works with state coastal zone management partners to:

- Preserve, protect, develop, and, where possible, restore and enhance the resources of the nation's coastal zone for this and succeeding generations;
- Encourage and assist the states to exercise effectively their responsibilities in the coastal zone to achieve wise use of land and water resources, giving full consideration to ecological, cultural, historic, and aesthetic values, as well as the need for compatible economic development;
- Encourage the preparation of special area management plans to provide increased specificity in protecting significant natural resources, reasonable coastal-dependent economic growth, improved protection of life and property in hazardous areas and improved predictability in governmental decision-making; and
- Encourage the participation, cooperation, and coordination of the public, Federal, state, local, interstate and regional agencies, and governments affecting the coastal zone.

To comprehensively manage our coastal resources and balance often competing land and water uses while protecting sensitive resources, state CZM programs are expected to:

- Protect natural resources;
- Manage development in high hazard areas;
- Manage development to achieve quality coastal waters;
- Give development priority to coastal-dependent uses;
- Have orderly processes for the siting of major facilities;
- Locate new commercial and industrial development in, or adjacent to, existing developed areas;
- Provide public access for recreation;
- Redevelop urban waterfronts and ports, and preserve and restore historic, cultural, and aesthetic coastal features;
- Simplify and expedite governmental decision-making actions;
- Coordinate state and Federal actions;
- Give adequate consideration to the views of Federal agencies;
- Assure that the public and local governments have a say in coastal decision-making; and
- Comprehensively plan for and manage living marine resources.

A unique aspect of CZM is “Federal Consistency,” which ensures that Federal actions that are reasonably likely to affect any land or water use or natural resource of the coastal zone will be consistent with the enforceable policies of a coastal state's or territory’s federally approved CZM Program. Federal consistency is the CZMA requirement where Federal agency activities that have reasonably foreseeable effects on any land or water use or natural resource of the coastal zone (also referred to as coastal uses or resources and coastal effects) must be consistent to the maximum extent practicable with the enforceable policies of a coastal state's federally approved coastal management program. (Federal agency activities, including federally permitted activities, are activities and development projects performed by a Federal agency, or a contractor for the benefit of a Federal agency.)

The Mississippi Coastal Program, approved by NOAA in 1980, is comprised of a network of agencies with authority in the coastal zone. The Mississippi Department of Marine Resources (MDMR), through the Office of Ecology, serves as the lead agency. MDMR is governed by a Commission on Marine Resources appointed by the Governor. The primary authority guiding the Coastal Program is the Coastal Marshlands Protection Act, which includes a wetlands plan designating the allowable use of the state's tidal wetlands. The Mississippi coastal zone includes the three coastal counties as well as all adjacent coastal waters and the barrier islands of the coast.

The Coastal Program is responsible for permitting, Federal consistency review, and the Coastal Nonpoint Pollution Control Program. Through the Coastal Preserves Program, MDMR protects and restores coastal habitats. The Comprehensive Resource Management Plan is the primary program through which MDMR provides technical assistance for managing coastal development, with a focus on stormwater management, smart growth, and GIS training.

The MsCIP environmental team has been working closely with the MDMR technical staff throughout the entire planning process. The Corps, Mobile District has determined that the MsCIP effort described in the MsCIP Comprehensive Report and Integrated Programmatic EIS to be consistent with the requirements of the CZM Act to the maximum extent practicable. The Corps, Mobile District will request formal concurrence with our determination following the completion of the comment period the EIS. Upon documentation receipt, this information will be included in this appendix.

3.3 AIR QUALITY

The Mississippi Department of Environmental Quality (MDEQ) is responsible for protecting the state's air, land, and water. The MDEQ, Air Division is responsible for ensuring that air quality within Mississippi is protective of public health and welfare. This division is charged with controlling, preventing, and abating air pollution to achieve compliance with air emission regulations pursuant to the Mississippi Air and Water Pollution Control Act, applicable regulations promulgated by the U.S. Environmental Protection Agency (USEPA), and the Federal Clean Air Act.

The Ambient Air Quality Standards for Mississippi are in Regulation APC-S-4 as described in the following:

MISSISSIPPI COMMISSION ON ENVIRONMENTAL QUALITY
REGULATION APC-S-4: AMBIENT AIR QUALITY STANDARDS

Adopted February 9, 1983
Last Amended June 27, 2002

Except for odor, as covered below, the ambient air quality standards for Mississippi shall be the Primary and Secondary National Ambient Air Quality Standards as duly promulgated by USEPA in (or to be printed in) 40 Code of Federal Regulation (CFR) Part 50, pursuant to the Federal Clean Air Act, as amended. All such standards promulgated by USEPA as of June 22, 1988, are hereby adopted and incorporated herein by the Commission by reference as the official ambient air quality standards of the State of Mississippi and shall hereafter be enforceable as such (except that the word "Administrator" in said standards shall be replaced by the words "Executive Director" and the word "Agency" in said standards shall be replaced by the word "Department").

There shall be no odorous substances in the ambient air in concentrations sufficient to adversely and unreasonably:

(1) affect human health and well-being;
(2) interfere with the use or enjoyment of property; or
(3) affect plant or animal life.

In determining that concentrations of such substances in the ambient air are adversely and unreasonably affecting human well-being or the use or enjoyment of property of plant or animal life, the factors to be considered by the Commission will include, without limiting the generality of the foregoing, the number of complaints or petitioners alleging that such a condition exists, the frequency of the occurrence of such substances in the ambient air as confirmed by the MDEQ staff, and the land use of the affected area.

Mississippi has adopted Federal Standards (New Source Performance Standards, National Emissions Standards for Hazardous Air Pollutants, etc.) by reference. State specific emissions standards for Mississippi are in:

- Regulation APC-S-1 - Air Emission Regulations for the Prevention, Abatement, and Control of Air Contaminants; and
- Regulation APC-S-8 - Air Toxic Regulations.

Jackson, Harrison, and Hancock Counties have been designated in attainment with the National Ambient Air Quality Standards. The proposed Mississippi Coastal Improvement Program effort will be in attainment with the State of Mississippi's Air Quality Standards.

3.4
COMPLIANCE WITH ENVIRONMENTAL LAWS AND REGULATIONS

1
2

Environmental Laws and Regulations

Law/Regulation/ Executive Order (EO)	Description	Principal Federal Responsible Agency(s)
Endangered Species Act (ESA) of 1973	Establishes a national policy designed to protect and conserve threatened and endangered (T&E) species and the ecosystems upon which they depend	U.S. Fish and Wildlife Service (USFWS) National Oceanic and Atmospheric Administration (NOAA) Fisheries
Marine Mammal Protection Act of 1972 (MMPA)	Prohibits the take (i.e., hunting, killing, capture, and/or harassment) of marine mammals, and enacts a moratorium on the import, export, and sale of marine mammal parts and products	NOAA Fisheries USFWS
National Historic Preservation Act of 1966 (NHPA) and EO 11593	Seeks to preserve the historical and cultural foundation of the U.S. EO 11593 of 1991 states the Federal Government will provide leadership in preserving, restoring, and maintaining the historic and cultural environment	Mississippi State Historic Preservation Officer (SHPO)
Clean Water Act (CWA)	Regulates activities resulting in a discharge to navigable waters Section 401 (33 U.S.C. 1341) of the CWA specifies that any applicant for a Federal license or permit to conduct any activity that may discharge into the navigable waters shall obtain a certification that the discharge complies with applicable sections of the CWA Section 402 established the National Pollutant Discharge Elimination System (NPDES), which regulates discharges into waters of the U.S. Section 404 established a program to regulate the discharge of dredged or fill material into waters of the U.S. to include tributaries to navigable waters, interstate wetlands which could affect interstate or foreign commerce, and wetlands adjacent to waters of the U.S.	U.S. Environmental Protection Agency (USEPA)
Clean Air Act (CAA)	Establishes limits on how much of an air pollutant can be present in an area anywhere in the U.S. to promote uniformity in basic health and environmental protections	USEPA
Coastal Zone Management Act (CZMA)	Establishes a national coastal management program that comprehensively manages and balances competing uses of and impacts to any coastal area or resource	NOAA, National Ocean Service
Farmland Protection Policy Act (FPPA)	Minimizes the extent to which Federal programs contribute to the unnecessary conversion of farmland to nonagricultural uses	U.S. Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS)
Wild and Scenic Rivers Act of 1968	Establishes a National Wild and Scenic Rivers System to protect and preserve the free-flowing waters of the nation's most spectacular rivers. The act safeguards the special character of these rivers while striving to balance river development with permanent protection. The act prescribes the methods and standards through which additional rivers may be identified and added to the system to study areas and submit proposals to the President and Congress for addition to the system.	Secretary of the Interior and the Secretary of Agriculture
Estuary Protection Act	Authorizes study and inventory of U.S. estuaries, including	Secretary of the Interior

of 1968	land and water of the Great Lakes, to determine whether such areas should be acquired by the Federal Government for protection	
Federal Water Project Recreation Act of 1965	Declares recreation and fish and wildlife enhancement be given full consideration as purposes of Federal water development projects if non-Federal public bodies agree to: (1) bear not less than one-half the separable costs allocated for recreational purposes or twenty-five percent of the cost for fish and wildlife enhancement; (2) administer project land and water areas devoted to these purposes; and (3) bear all costs of operation, maintenance and replacement	Secretary of the Interior
Resource Conservation and Recovery Act (RCRA) of 1976	Provides for comprehensive 'cradle-to-grave' regulation of hazardous waste and authorizes environmental agencies to order the cleanup of contaminated sites	USEPA
Toxic Substances Control Act (TSCA) of 1976	Enacted by Congress to give USEPA the ability to track the 75,000 industrial chemicals currently produced or imported into the U.S.	USEPA
Marine Protection, Research, and Sanctuaries Act of 1972 (MPRSA)	Regulates ocean dumping in the territorial seas or the contiguous zone of the U.S. and provides for general research on ocean resources (includes designation of marine sanctuaries) and ocean disposal activities	USEPA/NOAA
Section 9 of the Rivers and Harbors Act of 1899	Prohibits the construction of any bridge, dam, dike, or causeway over or in any port, roadstead, haven, harbor, canal, navigable river, or other navigable water of the U.S. until receiving consent of Congress	Corps
Coastal Barrier Resources Act (CBRA)	Designated various undeveloped coastal barrier islands, depicted by specific maps, for inclusion in the Coastal Barrier Resources System (System). Areas so designated were made ineligible for direct or indirect Federal financial assistance that might support development, including flood insurance, except for emergency life-saving activities. Exceptions for certain activities, such as fish and wildlife research, are provided, and National Wildlife Refuges and other, otherwise protected areas are excluded from the System.	Department of Interior, USFWS
EO 11988, Floodplain Management	Requires Federal agencies to avoid to the extent possible the long and short-term adverse impacts associated with the occupancy and modification of floodplains and to avoid direct and indirect support of floodplain development wherever there is a practicable alternative	Federal Emergency and Management Agency (FEMA)
EO 11990, Protection of Wetlands	Minimizes the destruction, loss or degradation of wetlands and preserves and enhances the natural and beneficial values of wetlands	USFWS
EO 12114, Environmental Effects Abroad of Major Federal Actions	Enables Federal agencies responsible for authorizing and approving actions to be informed of pertinent environmental considerations and to take such considerations into account, with other pertinent considerations of national policy, in making decisions regarding such actions	All Federal agencies
EO 12898: Environmental Justice	Requires Federal agencies to incorporate into NEPA documents an analysis of the environmental effects of their proposed programs on minorities and low-income	USEPA

	populations and communities.	
EO 13045: Protection of Children from Environmental Health Risks and Safety Risks	Each Federal agency is to make it a high priority to identify and assess environmental health risks and safety risks that may disproportionately affect children. The President also directed each Federal agency to ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks.	USEPA
Wilderness Act of 1964	Assures that an increasing population, accompanied by expanding settlement and growing mechanization, does not occupy and modify all areas within the U.S. and its possessions, leaving no lands designated for preservation and protection in their natural condition, it is hereby declared to be the policy of the Congress to secure for the American people of present and future generations the benefits of an enduring resource of wilderness.	All Federal agencies
Magnuson Fishery Conservation and Management Act and Essential Fish Habitat (EFH)	Establishes and delineates an area from the states' seaward boundary out 200 nautical miles as a fisheries conservation zone for the U.S. and its possessions Established national standards for fishery conservation and management, and created eight regional Fishery Management Councils (FMCs) to apply those national standards in FMCs EFH is defined as the water and substrate necessary for fish spawning, breeding, feeding, and growth to maturity.	NOAA Fisheries

DRAFT

February 2009

Mississippi Coastal Improvements Program (MsCIP) Hancock, Harrison, and Jackson Counties, Mississippi

Appendix B Economic

FOREWORD

This document is one of a number of technical appendices to the Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan and Integrated Feasibility Report and Environmental Impact Statement.

The Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan Integrated Feasibility Report and Environmental Impact Statement provides systems-based solutions and tentatively-selected recommendations that address: hurricane and storm damage reduction, ecosystem restoration and fish and wildlife preservation, reduction of damaging saltwater intrusion, and reduction of coastal erosion. The tentatively-selected recommendations contained in the Main Report/EIS also provide measures that aid in: greater coastal environmental and societal resiliency, regional economic re-development, and measures to reduce long-term risk to the public and property, as a consequence of hurricanes and coastal storms. The tentatively-selected recommendations cover a comprehensive package of projects and activities that treat the environment, wildlife, and people, as an integrated system that requires a multi-tiered and phased approach to recovery and risk reduction, irrespective of implementation authority or agency.

The MsCIP Study Area

The purpose of the Comprehensive Plan Report is to present, to the Congress of the United States, the second of two packages of tentatively-selected recommendations (i.e., the first being the "interim" recommendations funded in May 2007, and this "final" response, as directed by the Congress), directed at recovery of vital water and related land resources damaged by the hurricanes of 2005, and development of tentatively-selected recommendations for long-term risk reduction and community and environmental resiliency, within the three-county, approximately 70 mile-long coastal zone, including Mississippi Sound and its barrier islands, of the State of Mississippi.

This appendix, the Main Report/EIS, and all other appendices and supporting documentation, were subject to Independent Technical Review (ITR) and an External Peer Review (EPR). Both review processes will have been conducted in accordance with the Corps "Peer Review of Decision Documents" process, has been reviewed by Corps staff outside the originating office, conducted by a Regional and national team of experts in the field, and coordinated by the National Center of Expertise in Hurricane and Storm Damage Protection, North Atlantic Division, U.S. Army Corps of Engineers.

The report presents background on the counties that comprise the Mississippi coastline most severely impacted by the Hurricanes of 2005, their pre-hurricane conditions, a summary of the effects of the 2005 hurricane season, problem areas identified by stakeholders and residents of the study area, a summary of the approach used in analyzing problems and developing tentatively-selected recommendations directed at assisting the people of the State of Mississippi in recovery, recommended actions and projects that would assist in the recovery of the physical and human environments, and identification of further studies and immediate actions most needed in a comprehensive plan of improvements for developing a truly resilient future for coastal Mississippi.

This appendix contains detailed technical information used in the analysis of existing and future without-project conditions, in the development of problem-solving measures, and in the analysis, evaluation, comparison, screening, and selection of alternative plans, currently presented as tentatively-selected recommendations contained in the Main Report/EIS.

Each appendix functions as a complete technical document, but is meant to support one particular aspect of the feasibility study process. However, because of the complexity of the plan formulation process used in this planning study, the information contained herein should not be used without parallel consideration and integration of all other appendices, and the Main Report/EIS that summarizes all findings and tentatively-selected recommendations.

The intent of the economic appendix is to outline the economic evaluation conducted for the Mississippi Coastal Improvements Programs (MsCIP) Comprehensive Plan. This appendix will display the National Economic Development (NED) benefits, Regional Economic Development (RED) benefits, Environmental Quality (EQ) benefits, Other Social Effects (OSE), and costs that were evaluated for the various Comprehensive Plan measures. The intent of this appendix is to demonstrate the cost effectiveness of measures. Tentatively-selected recommendations of cost effective plans are outlined in the MsCIP Main Report, and are based on the data from this appendix, other technical appendices, and the results of the Risk Informed Decision Framework (RIDF) evaluations.

Contents

CHAPTER I. DEFINING THE STUDY AREA 1
1.3.1 Planning Zones 1
1.3.2 Planning Units 2
1.3.3 Planning Sub-Units 2

CHAPTER II. OVERVIEW OF ECONOMIC METHODOLOGY 7

CHAPTER III. MODELING EFFORTS 10
3.1 Corps of Engineers Flood Inventory Tool (CEFIT) 10
3.1.1 Program Overview 10
3.1.2 Extent of Use 11
3.1.3 Uncertainty 11
3.2 Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) 11
3.2.1 Program Overview 11
3.2.2 Depth Damage Relationships 13
3.2.3 Extent of Use 14
3.2.4 Uncertainty 14
3.3 Beach-FX 14
3.3.1 Program Overview 14
3.3.2 Depth Damage Functions 15
3.3.3 Extent of Use 15
3.3.4 Uncertainty 15
3.4 Institute for Water Resources (IWR) Planning Suite 16
3.4.1 Program Overview 16
3.4.2 Extent of Use 17
3.4.3 Uncertainty 17
3.5 Economic Impact Forecasting Systems (EIFS) 18
3.5.1 Program Overview 18
3.5.2 Extent of Use 18
3.5.3 Uncertainty 19

CHAPTER IV. DATA COLLECTION METHODOLOGY 20
4.1 Damage Categories 21
4.2 Occupancy Types 21
4.3 First Floor Elevations 29
4.4 Structure Values 30
4.4.1 Residential Structure Values 30
4.5 Content Values 35

CHAPTER V. INVENTORY AND FORECASTING CONDITIONS 40
5.1 Historic Conditions 40
5.1.1 Impacts of Hurricane Camille 40
5.1.2 Historic (Pre-Hurricane) Population Trends 41
5.1.3 Historic (Pre-Hurricane Katrina) Environmental Setting 42
5.2 Existing (Post-Hurricane Katrina) Conditions 43
5.2.1 Impacts from Hurricane Katrina 43
5.2.2 Existing Structure Conditions 44

5.2.3 Existing (Post-Hurricane Katrina) Socio-economic Conditions 52
5.2.4 Existing (Post-Hurricane Katrina) Environmental Setting 60
5.3 Future Without-Project Conditions 61
5.3.1 Period of Analysis 61
5.3.2 Assumptions 62
5.3.3 Scenario Testing 64
5.3.4 Future Without-Project Surge Risk 70
5.3.5 Summary of Future Without-Project Damages 74
5.3.6 Impacts of Redevelopment Scenarios on Equivalent Annual Without-Project Damages 83
5.3.7 Impacts of Relative Sea Level Rise on Equivalent Annual Without-Project Damages 86

CHAPTER VI. DEVELOPMENT AND EVALUATION OF MEASURES 90
6.1 Overview of Benefits and Cost Evaluation 90
6.1.1 Calculation of National Economic Development Benefits 90
6.1.2 Calculation of Costs 91
6.1.3 Calculation of Regional Economic Development Benefits 93
6.2 Evaluation of Barrier Island Measures 94
6.2.1 General Description 94
6.2.2 List of Measures 104
6.2.3 With-Project Conditions 107
6.2.4 Summary of Costs 108
6.2.5 Regional Economic Development (EIFS Model) 108
6.2.6 Summary of Costs and Benefits 109
6.3 Evaluation of Beach and Dune Construction Measures 110
6.3.1 Planning Unit One 110
6.3.2 Panning Unit Two 121
6.3.3 Planning Unit Three 133
6.4 Seawall and Elevated Roadway Area Measures 143
6.4.1 General 143
6.4.2 Historic (Pre-Hurricane Katrina) Conditions 143
6.4.3 Opportunities 147
6.4.4 Assumptions 147
6.4.5 Measures 147
6.4.6 National Economic Development (NED) 148
6.4.7 Environmental Quality (EQ) 150
6.4.8 Summary of Costs 152
6.4.9 Regional Economic Development (RED) 152
6.5 Evaluation of Pearlington Area Measures 154
6.5.1 General 154
6.5.2 Opportunities 155
6.5.3 Assumptions 155
6.5.4 Measures 155
6.5.5 National Economic Development (NED) 156
6.5.6 Environmental Quality (EQ) 164
6.5.7 Summary of Costs 165
6.5.8 Regional Economic Development (RED) 165
6.6 Admiral Island Ecosystem Restoration Measures 167
6.6.1 Formulation of Alternatives 167

6.6.2 Comparison of Alternatives 173
6.6.3 Regional Economic Development (RED) Benefits 176
6.7 Evaluation of Turkey Creek Ecosystem Restoration Measures 177
6.7.1 Formulation of Alternatives 177
6.7.2 Comparison of Alternatives 183
6.7.3 Regional Economic Development Benefits 185
6.8 Evaluation of Ocean Springs Area Measures 187
6.8.1 General 187
6.8.2 Opportunities 188
6.8.3 Assumptions 188
6.8.4 Measures 188
6.8.5 National Economic Development (NED) 189
6.8.6 Environmental Quality (EQ) 197
6.8.7 Summary of Costs 198
6.8.8 Regional Economic Development (RED) 199
6.9 Evaluation of Gautier Area Measures 200
6.9.1 General 200
6.9.2 Opportunities 200
6.9.3 Assumptions 200
6.9.4 Measures 201
6.9.5 National Economic Development (NED) 202

LIST OF ACRONYMS

AAFU – Average Annual Functional Units

ABFE – Advisory Base Flood Elevation

BFE – Base Flood Elevation

CEFIT – Corps of Engineers Flood Inventory Tool

EAD – Equivalent Annual Damages

EIFS – Economic Impact Forecast System

EGM – Economic Guidance Memorandum

EM – Engineering Manual

EQ – Environmental Quality

ER – Engineering Regulation

ERDC – Engineer Research and Development Center

FEMA – Federal Emergency Management Agency

FHI – Functional Habitat Unit

HEC-FDA – Hydrologic Engineering Centers - Flood Damage Analysis

IWR – Institute for Water Resources

LaCPR – Louisiana Coastal Protection and Restoration

MEMA – Mississippi Emergency Management Agency

MPI – Maximum Probable Intensity

MsCIP – Mississippi Coastal Improvements Program

NAVD88 – North American Vertical Datum 1988

NED – National Economic Development Benefits

NFIP –National Flood Insurance Program

OSE – Other Social Effects

P&G – Planning and Guidance

RED – Regional Economic Development

ROM Costs – Rough Order Magnitude Costs

USACE – US Army Corps of Engineers

EXECUTIVE SUMMARY

General

The intent of the economic appendix is to outline the economic evaluation conducted for the Mississippi Coastal Improvements Programs (MsCIP) Comprehensive Plan. This appendix will display the National Economic Development (NED) benefits, Regional Economic Development (RED) benefits, Environmental Quality (EQ) benefits, Other Social Effects (OSE), and costs that were evaluated for the various Comprehensive Plan measures. The intent of this appendix is to demonstrate the cost effectiveness of measures. Plan features of cost effective plans are outlined in the MsCIP Main Report, and are based on the data from this appendix, other technical appendices, and the results of the Risk Informed Decision Framework (RIDF) evaluations.

Authorizing Language

The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: ***"For an additional amount for "investigations" to expedite studies of flood and storm damage reduction related to the consequences of hurricanes in the Gulf of Mexico and Atlantic Ocean in 2005, $37,300,000 to remain available until expended: Provided, that using $10,000,000 of the funds provided, the Secretary shall conduct an analysis and design for comprehensive improvements or modifications to existing improvements in the coastal area of Mississippi in the interest of hurricane and storm damage reduction, prevention of saltwater intrusion, preservation of fish and wildlife, prevention of erosion, and other related water resource purposes at full Federal expense; Provided further, that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits; Provided further, that interim plan features for near term improvements shall be provided within 6 months of enactment of this act with final plan features within 24 months of this enactment."***

The requirements laid out in this authorizing language are unique in their direction that the study team use neither incremental cost-benefit analysis nor maximization of net national economic development (NED) benefits in the selection of plan features. This provided a unique opportunity, but also the requirement that the team very carefully describe the plan formulation and selection process developed for this study effort.

Study Purpose and Scope

The purpose of the comprehensive study is to present the second of two packages of tentatively-selected plan features, the "final" response requested by Congress, directed at recovery of vital water and related land resources damaged by the hurricanes of 2005 within the three-county coastal region of the State of Mississippi. The report presents background on the three coastal counties that comprise the Mississippi coastline most severely impacted by the Hurricanes of 2005, their pre-hurricane conditions, a summary of the effects of the 2005 hurricane season, problem areas identified by stakeholders and residents of the study area, a summary of the approach used in analyzing problems and developing plan features directed at assisting the people of the State of Mississippi in recovery, recommended actions and projects that would assist in the recovery of the

physical and human environments, and identification of further studies and immediate actions most needed in a comprehensive plan of improvements for coastal Mississippi.

Study Area

Delineation of the study area is critical for the evaluation of benefits and for their aggregation to determine the economic value of proposed measures. The over all study area for this analysis is the three coastal Mississippi counties; Hancock, Harrison, and Jackson from west to east respectively. The area was further delineated into planning zones, planning units, and planning sub-units.

The first delineation in the hierarchy of segregating the study area was the creation of four planning zones, as shown below in figure 1. The planning zones span the width of Mississippi from state line to state line, and run from south to north. The four zones have been titled the Off-shore Zone, the Coastal Zone, the Inland Zone, and the Upland Zone from south to north respectively. The Off-shore zone includes all areas south of the Mississippi Sound shoreline. The Coastal Zone includes all areas generally from the shoreline North to the CSX railroad and terminating at the Port Bienville railroad spur in Hancock County and Hwy 52 in Jackson County. The Inland Zone accounts for all areas north of the Coastal Zone to the MPI storm surge limit, and the Upland Zone extends from north of the MPI storm surge limit to the County lines.

For the comprehensive plan, the three coastal counties were divided into three planning units based on watershed boundaries which, coincidentally, align with the county jurisdictions. Planning unit one begins at the western state boundary, or the east bank of the Pearl River, and continue to the midpoint of St. Louis Bay. Planning unit two begins at the midpoint of St. Louis Bay and continues east to the midpoint of Biloxi Bay. Planning unit three extends from the midpoint of Biloxi Bay east to the border of Mississippi and Alabama.

Further delineation of the area required breaking the planning units into fifty-four planning sub-units based on hydrologic characteristics, population centers, and economic considerations of potential measure. For hydraulic considerations, Hurricane Surge Atlas maps were evaluated. These maps were prepared by FEMA and the Corps of Engineers, Mobile District from **SLOSH** (Sea, Lake, and Overland Surges from Hurricanes) programming done by the National Oceanic &Atmospheric Administration (NOAA). Sub-units were delineated so that the maximum storm surge difference between sub-units was approximately two-feet. Planning unit one includes ten sub-units, planning unit two eighteen sub-units, and planning unit three twenty-six sub-units. Figure 2 depicts the 54 planning sub-units.

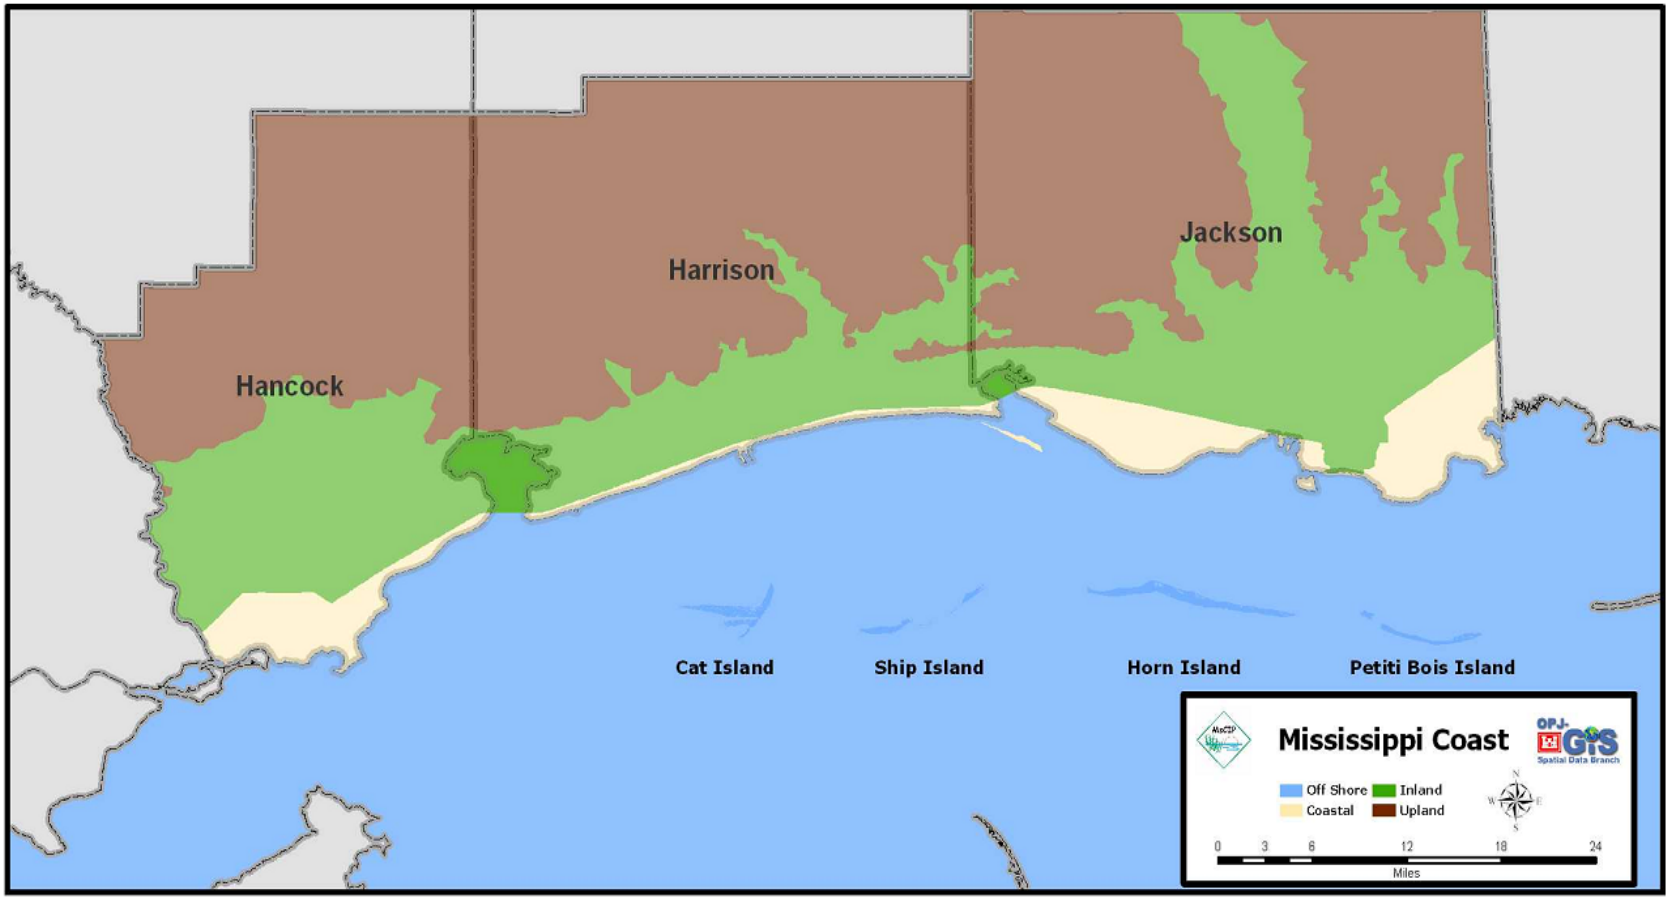

Figure 1. MsCIP Planning Zones

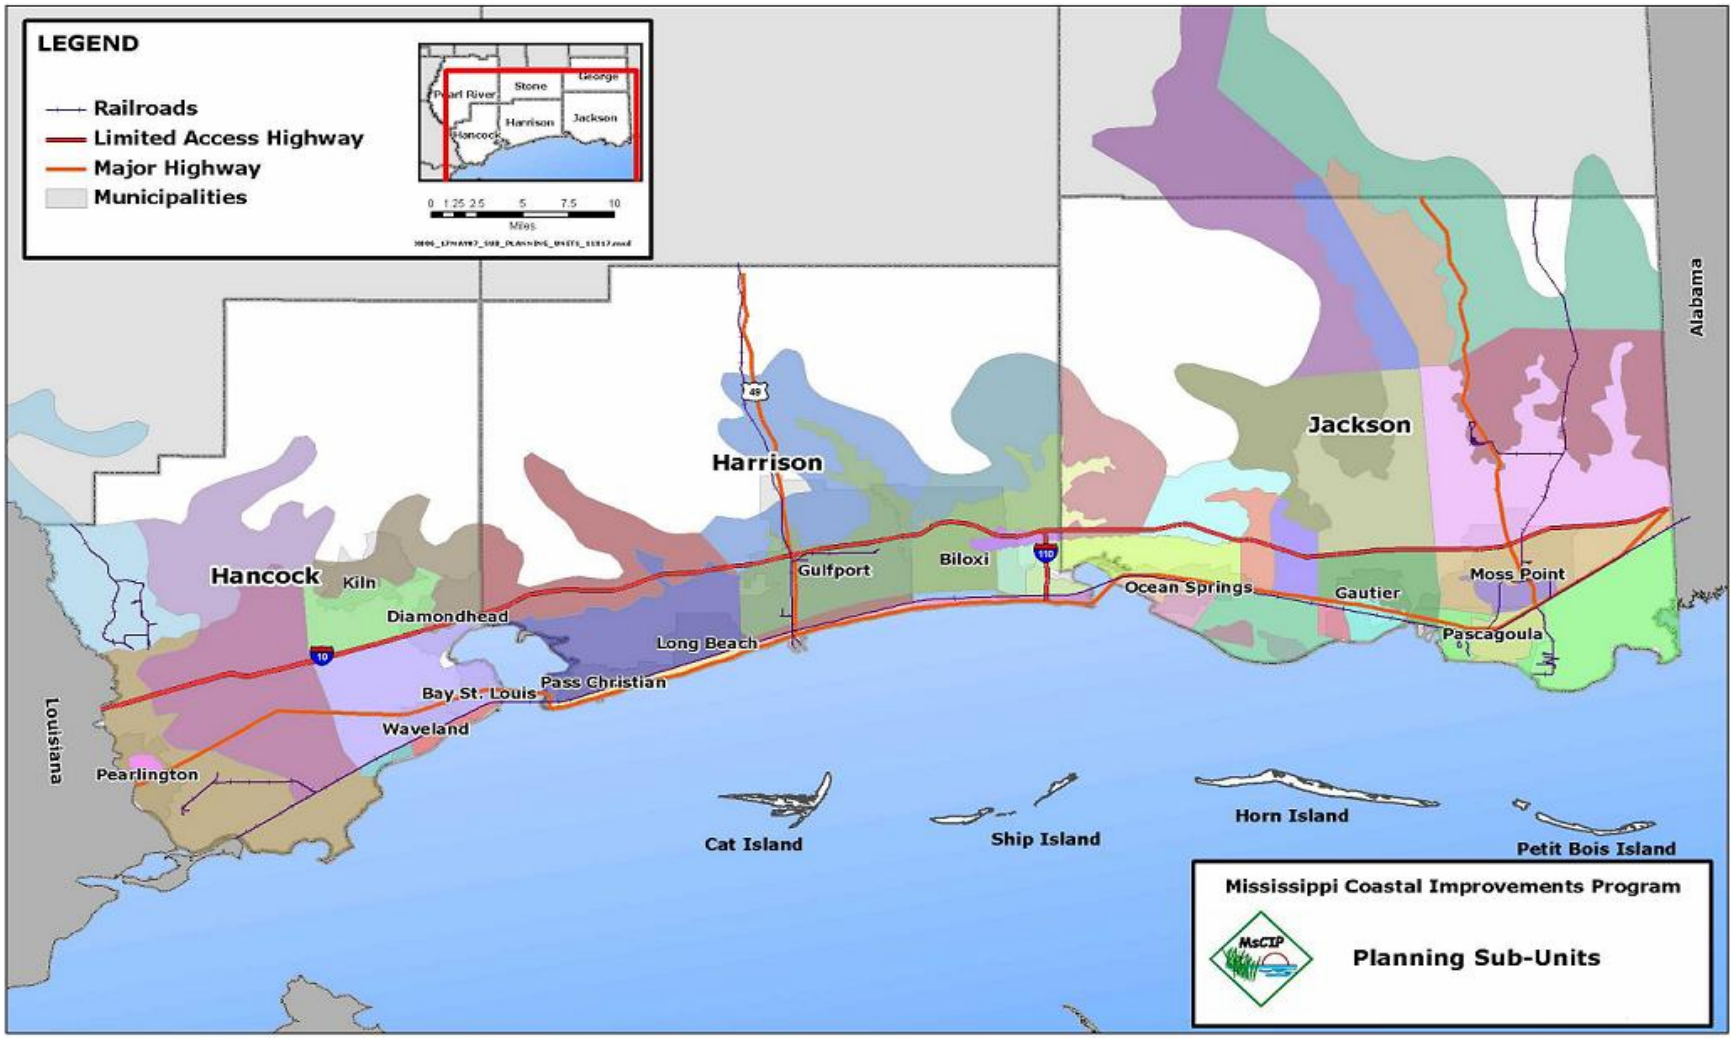

Figure 2. Overview of 3 planning units 54 planning sub-units

Economic Methodology

The economic methodology was developed to seamlessly fit into the six step planning process and current Corps guidance. The six step planning process, as defined by the Engineering Regulation (ER) 1105-2-100; Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (U.S. Water Resources Council 1983), referred to as the P&G, is:

1/ Identify Problems and Opportunities
2/ Inventory and Forecast Conditions
3/ Develop Alternatives
4/ Evaluate Alternatives
5/ Compare Alternatives
6/ Select the Recommended Plan

The Mississippi Gulf Coast is a complex system that is made up of a diverse blend of ecological and human habitats. Given those complexities, a fluid and flexible process was needed to evaluate and aggregate the benefits of potential measures and measures. The process incorporates data collection, forecasting techniques, scenario planning, cost effective evaluation using state of the art modeling techniques, and the communication of both benefits and risks associated with potential measures and measures. Figure 3 outlines the process used for this analysis.

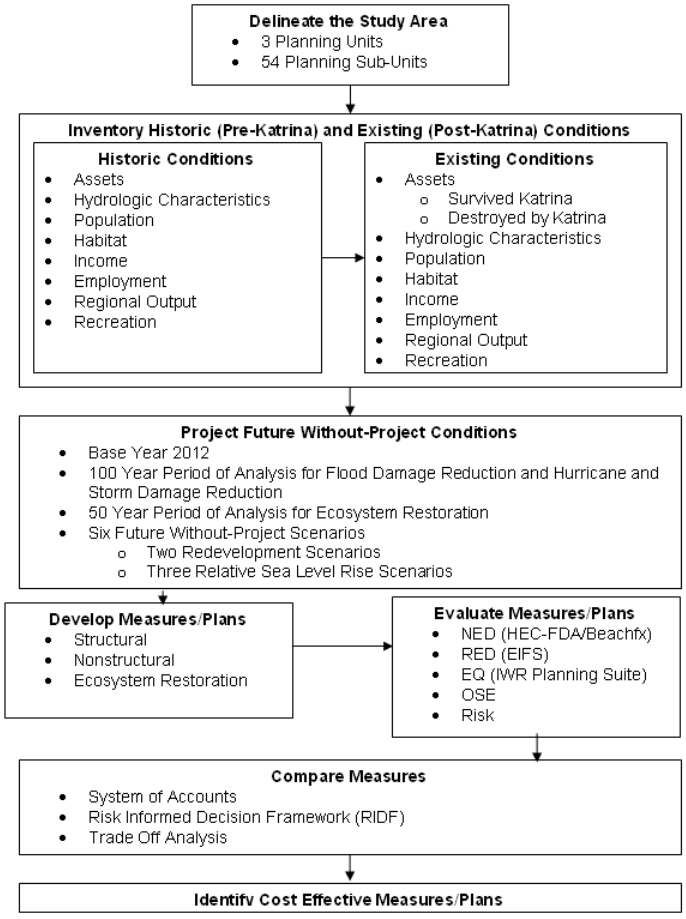

Figure 3. Overview of Economic Methodology

Historic Conditions

The Mississippi Gulf Coast is no stranger to large storm surge events. On August 17, 1969, Hurricane Camille impacted the area in a similar fashion to Hurricane Katrina. Hurricane Camille made landfall at Bay St. Louis, Mississippi only miles way from Hurricane Katrina's landfall path. The total surge area ranged from lower Plaquemines Parish in Louisiana to Perdido Pass, Alabama. Maximum surge from Hurricane Camille on the Mississippi coast ranged from 21.7-feet above m.s.l. in planning unit one, to 24.2-feet above m.s.l. in planning unit two, and 15.8-feet above m.s.l. in planning unit 3.

Damage to the Mississippi Coast from Hurricane Camille was extensive. Federal relief expenditures topped 100 million dollars at 1970 prices, over 600 million dollars when accounted for inflation. The magnitude of this number is astounding considering that many of the relief programs that exist today did not exist for Hurricane Camille. Table 1 shows selected Hurricane Camille damage statistics. Tables 2 and 3 show damage to residential and commercial structures caused by Hurricane Camille surge.

Table 1.
Select Hurricane Camille Statistics.

Camille Statistics	Mississippi	Louisiana	Alabama
Persons Dead	135	9	Unknown
Persons Missing	27	0	Unknown
Families Suffering Loss	63,665	9,442	750
Dwellings Destroyed	3,881	1,771	10
Dwellings with major damage	12,112	1,753	50
Dwellings with minor damage	29,736	3,697	500

The 1950-2000 population levels and growth for the U.S., Mississippi, the three-county study area, and each county are presented in Table 3. During this fifty year period, the population of the three-county study area grew by 186.6 percent. This is 5.6 times the Mississippi percentage population

growth of 33.2 percent and 2.2 times the U.S. percentage population growth of 86.0 percent for the same timeframe. The three-county area accounted for 32.7 percent of the nominal population growth for Mississippi from 1950 to 2000.

Table 3.
1950-2000 Population Levels and Growth (in thousands)

	United States	Mississippi	Three-County Study Area	Hancock County	Harrison County	Jackson County
1950	151,326	2,179	127	12	84	31
1960	179,323	2,178	189	14	119	56
1970	203,212	2,217	239	17	134	88

Existing Conditions

On August 29, 2005, Hurricane Katrina made land fall in Hancock County, Mississippi just east of the Pearl River. By virtually all accounts, it was the single largest disaster in U.S. history. Storm surge from Hurricane Katrina was the largest that has ever hit the continental United States. The surge inundated approximately 484 square miles of southern Mississippi. The relief expenditures in Mississippi alone have totaled in the billions of dollars.

The three planning units suffered tremendous devastation from Hurricane Katrina's surge. It is estimated that 32,446 structures were significantly destroyed (at least fifty-percent or more), with another 15,000 to 25,000 suffering moderate to minimal inundation damage. Of the structures sustaining significant destruction, 9,555 were in planning unit one, 16,528, in planning unit two, and 6,363 in planning unit three. Of those significant loss structures, approximately 19,000 claims were paid out by the Federal Emergency Management Agency's (FEMA's) National Flood Insurance Program (NFIP) totally over $2.3 Billion dollars, with the average claim around $137,000. Currently, no accurate data exists for uninsured losses, but estimates also range in the billions of dollars. Table 4 displays the significantly damaged structures by planning unit and by structure category. Figure 4 shows an example of the destruction caused by Hurricane Katrina in the planning unit one.

Table 4.
Structures Damaged 50% or More by Planning Unit and by Category

	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Commercial	1,267	1,794	378	**3,439**
Residential	8,099	14,500	5,780	**28,379**
Municipal	127	89	136	**352**
Mobile Home	62	145	69	**276**

Future Without-Project Conditions

Forecasting future "without-project" conditions is an important part of the Corps planning process. In order to evaluate the true economic value of potential measures over the project life, a forecast is created based on the historic and existing information, as well as quantitative and qualitative assumptions about what may happen within the study area in the future. In addition to forecasting of future "without-project" conditions, this study also evaluated alternative re-development and relative sea-level rise scenarios. This "Scenario Forecasting" technique was used for the MsCIP Comprehensive Plan in an attempt to capture uncertainty pertaining to these two key variables. For this purpose, six future "without-project" scenarios were developed and are summarized in Table 6.

Table 6.
Overview of Future Scenarios

Future Scenario	Redevelopment Type	Relative Sea Level Rise	Description
Future Scenario 1	Residential	Historical Only	Rebuild structures as existed pre-Hurricane Katrina with no relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 2	Mixed Residential & Commercial	Historical Only	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, no relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 3	Residential	Expected	Rebuild structures as existed pre-Hurricane Katrina with up to 2.4-feet relative sea level rise over the 100-year period of analysis. This future scenario applies to all three planning units.
Future Scenario 4	Mixed Residential & Commercial	Expected	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, an up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 5	Residential	High	Rebuild structures as existed pre-Hurricane Katrina with up to 3.4-feet of relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 6	Mixed Residential & Commercial	High	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, up to3.4-feet of relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.

Future Scenarios One and Two are included only to evaluate the effects of relative sea level rise. These Future scenarios will not be used in the evaluation of potential measures. Futures Three, Four, Five, and Six will be the future scenarios by which potential measures will be evaluated depending on the planning unit.

Structure inventory data was developed for the six future without-project scenarios including structure categories, structure value, content value, and other characteristics, which were input into the HEC-FDA program. Tables 7, 8, and 9 show a summary of select structure characteristics by future without-project scenario and table 10 summarizes the average annual without-project damages by future without-project scenario.

Table 7.
Future Without-Project Scenarios One, Three, and Five Inventory Parcels by Planning Unit and by Structure Category

Planning Unit Three	$88,670,000	$88,670,000	$104,700,000	$104,700,000	$122,420,000	$122,420,000
Total	**$378,890,000**	**$385,410,000**	**$426,030,000**	**$434,040,000**	**$475,200,000**	**$483,700,000**

Damages are rounded to the nearest ten thousand.

Evaluation of Measures and Alternatives

Initial analysis yielded an extensive list of potential measures that were appropriate to a given site or problem area. The sites/problem areas are illustrated in the Main Report. The development of preliminary measures for structural and non-structural damage reduction is discussed in detail in the Engineering Appendix. The development of preliminary measures for ecosystem restoration and saltwater intrusion remediation is discussed in detail in the Environmental Appendix.

Many measures were initially evaluated and screened, based on technical or environmental criteria, and are not discussed here. Those measures that were found to be technically sound for a particular application, and environmentally sound, in regards to potential impacts to environmental resources, were forwarded for evaluation. The development of more detail included preliminary design and cost estimation, coastal, hydrologic and/or hydraulic analysis and design, environmental analysis, and determination of potential damages prevented, residual damages, and other factors. Models used to evaluate the benefits of the measures included the Corps of Engineers Flood Inventory Tool (CEFIT), the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) program, the Beach-FX program, the Institute for Water Resources (IWR) Plan program, and the Economic Impact Forecasting System (EIFS).

Tentatively-Selected Plan features

The system wide plan features for the MsCIP Comprehensive plan, explained in more detail in the Main Report, have multiple levels. Some of the features will be recommended as work for entities other than the Corps of Engineers, some will be recommended for further construction, and some will be recommended for implementation. The list of measures in this appendix which are recommended for further study include the ring levee and nonstructural measures at the Pearlington, Ocean Springs, Gautier, Gulf Park Estates, Belle Fontaine, and Pascagoula/Moss Point areas, as well as further inquiry into the coast wide 20-foot, 30-foot, and 40-foot elevation nonstructural measures. Among the list of tentatively-selected plan features for construction that were analyzed in this appendix include barrier island restoration, beach and dune placement, ecosystem restoration at the Admiral Island, Turkey Creek, Bayou Cumbest, Dantzler, and Franklin Creek areas, the 21-foot elevation levee at the Forrest Heights area, and the acquisition of parcels within high risk areas.

For planning and screening purposes, the analysis in this appendix used a 100-year period of analysis for measures that were determined to be complex in nature such as the barrier island restoration or measures that had a high risk of residual damages due to relative sea level rise such as flood risk management measures. Other measures that were not as complex in nature, such as the beach and dune placement and the ecosystem restoration measures were evaluated at the traditional 50-year period of analysis used in Corps of Engineers studies. In order to show consistency among the plans recommended for construction, those measures that were initially screened at a 100-year period of analysis have been converted to a 50-year period of analysis for costs and benefits and are summarized in table 11. The costs in table 11 represent Rough Order Magnitude (ROM) utilized for screening. Detailed Micro-Computer Aided Cost Estimating System (MCACES) costs can be found in the cost estimating appendix.

Table 11.
Summaries of Benefits and Costs for Measures Recommended for Implementation[1]

	Equivalent annual damages Reduced Future 3 (Annual $)	Recreation (Annual $)	Environmental Impacts	Changes in Sales Volume ($)	Changes in Income ($)	Changes in Employment	Total First Cost with IDC[2] ($)	Average Annual Cost (Annual $)
Barrier Island Restoration	$18,028,000	$466,000	$43,618,000 Fishery Losses Avoided	$798,984,000	$167,850,000	4,920	$370,439,000	$20,372,000
Beach and Dune Placement	Moderate Reduction	N/A	736 Functional Habitat Index (FHI) Score	$33,413,200	$7,307,000	208	$15,890,800	$854,000
Acquisition in High Risk Areas	$22,000,000 to $33,000,000	Potential Recreational Opportunities	Potential Restoration Opportunities	$3,238,602,000	$706,330,000	19,452	$447,274,000	$18,532,000
Forrest Heights 21-FT Ring Levee	$89,000	N/A	3.6 Acres Impacted	$30,425,000	$6,440,000	193	$11,652,000	$740,000
Admiral Island Ecosystem Rest.	Increased Surge Storage	N/A	60 Average Annual Functional Units (AAFU)	$49,750,000	$ 11,996,000	301	$24,320,000	$1,364,000
Turkey Creek Ecosystem Rest.	Increased Surge Storage	N/A	1,565 Average Annual Functional Units (AAFU)	$15,237,000	$3,226,000	97	$6,017,000	$370,000
Bayou Cumbest Ecosystem Rest.	Increased Surge Storage	N/A	188 Average Annual Functional Units (AAFU)	$54,073,000	$ 10,546,000	306	$23,870,000	$1,396,000
Dantzler Ecosystem Rest.	Increased Surge Storage	N/A	1,244 Average Annual Functional Units (AAFU)	$ 5,054,000	$ 986,000	29	$1,922,000	$129,000
Franklin Creek Ecosystem	Increased Surge Storage	N/A	516 Average Annual Functional Units (AAFU)	$3,890,000	$ 759,000	22	$1,670,000	$101,000

1/ These measures were analyzed for economic benefits and do not represent the entire tentatively-selected plan features for implementation. See the main report for more detail.
2/ Implementation costs are based on ROM cost estimates and an FY 08 price level and do not include escalation. See the engineering appendix for more details on the costs.
3/ Average annual damages reduced and costs are based on a 50-year period of analysis and an FY 08 discount rate of 4.875-percent. Dollar values are rounded to the nearest thousand.

CHAPTER I. DEFINING THE STUDY AREA

This section describes the location and delineation of the study area used in this analysis. Delineation of the study area is critical for the evaluation of benefits and for their aggregation to determine the economic value of proposed measures. The over all study area for this analysis is the three coastal Mississippi counties; Hancock, Harrison, and Jackson from west to east respectively. The area was further delineated into planning zones, planning units, and planning sub-units which are detailed in the following subsections. Figure 1-1 shows the congressionally mandated study area for the Mississippi Coastal Improvements Program.

Figure 1-1. Congressionally authorized study area

1.3.1 Planning Zones

The first delineation in the hierarchy of segregating the study area was the creation of four planning zones. The planning zones span the width of Mississippi from state line to state line, and run from south to north. The four zones have been titled the Off-shore Zone, the Coastal Zone, the Inland Zone, and the Upland Zone from south to north respectively. The Off-shore zone includes all areas south of the Mississippi Sound shoreline. The Coastal Zone includes all areas generally from the shoreline North to the CSX railroad and terminating at the Port Bienville railroad spur in Hancock County and Hwy 52 in Jackson County. The Inland Zone accounts for all areas north of the Coastal Zone to the MPI storm surge limit, and the Upland Zone extends from north of the MPI storm surge limit to the County lines. Figure 1-2 depicts the four planning zones.

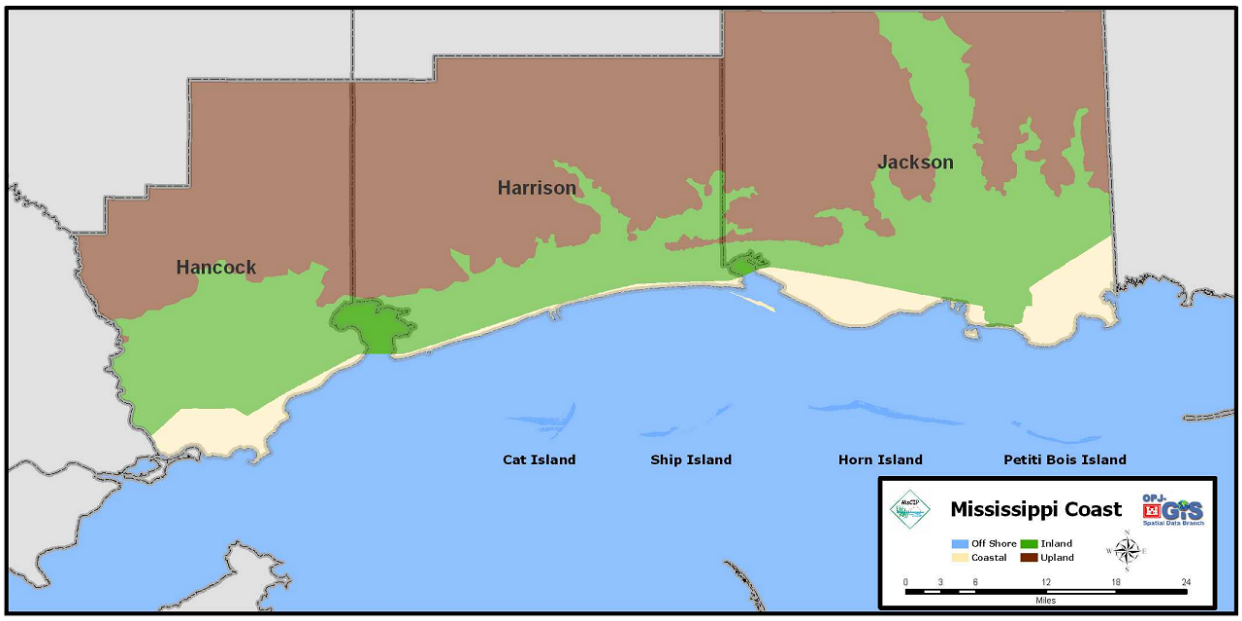

Figure 1-2. Planning Zones

1.3.2 Planning Units

For the comprehensive plan, the three coastal counties were divided into three planning units based on watershed boundaries which, coincidentally, align with the county jurisdictions. Planning unit one begins at the western state boundary, or the east bank of the Pearl River, and continue to the midpoint of St. Louis Bay. Planning unit two begins at the midpoint of St. Louis Bay and continues east to the midpoint of Biloxi Bay. Planning unit three extends from the midpoint of Biloxi Bay east to the border of Mississippi and Alabama. Figure 1-3 shows the planning unit boundaries.

1.3.3 Planning Sub-Units

Further delineation of the area required breaking the planning units into fifty-four planning sub-units based on hydrologic characteristics, population centers, and economic considerations of potential measure. For hydraulic considerations, Hurricane Surge Atlas maps were evaluated. These maps were prepared by FEMA and the Corps of Engineers, Mobile District from **SLOSH** (Sea, Lake, and Overland Surges from Hurricanes) programming done by the National Oceanic &Atmospheric Administration (NOAA). Sub-units were delineated so that the maximum storm surge difference between sub-units was approximately two-feet. Planning unit one includes ten sub-units, planning unit two eighteen sub-units, and planning unit three twenty-six sub-units. Figures 1-4 shows all the sub-units and figures 1-5, 1-6, and 1-7 illustrate the planning units one, two, and three and their sub-units, respectively.

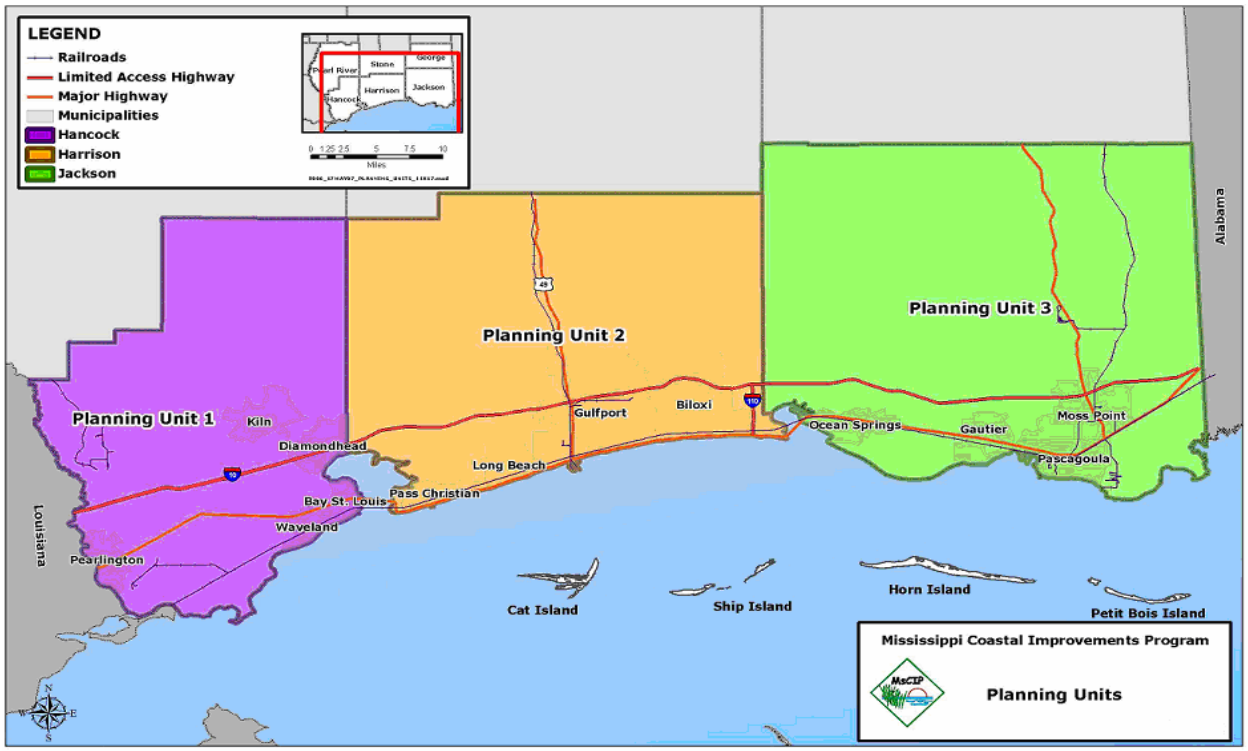

Figure 1-3. Planning Units

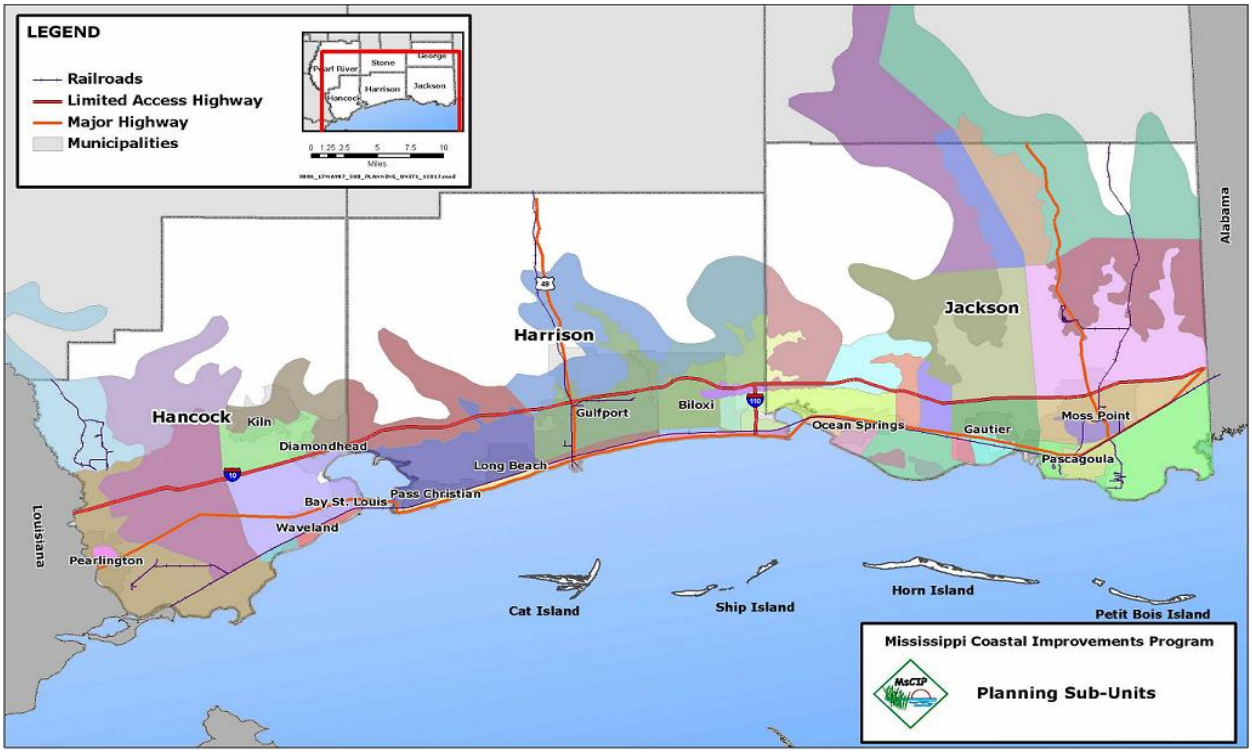

Figure 1-4. Overview of 54 planning sub-units

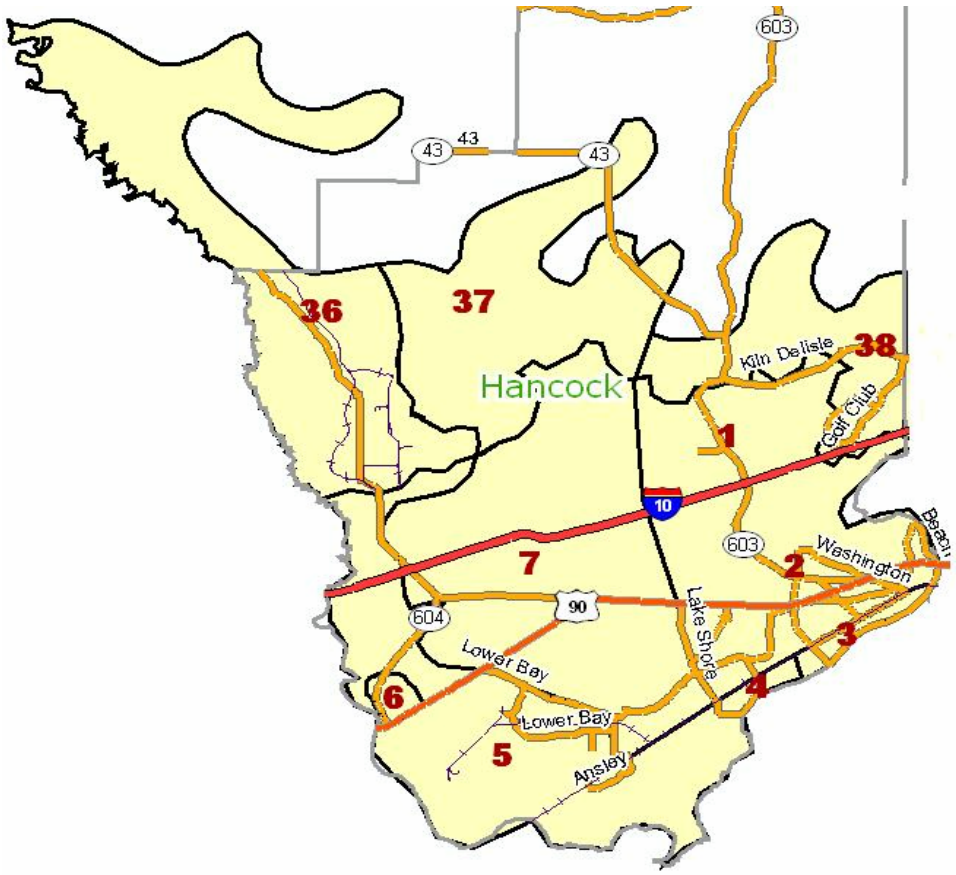

Figure 1-5. Sub-units for Planning Unit One

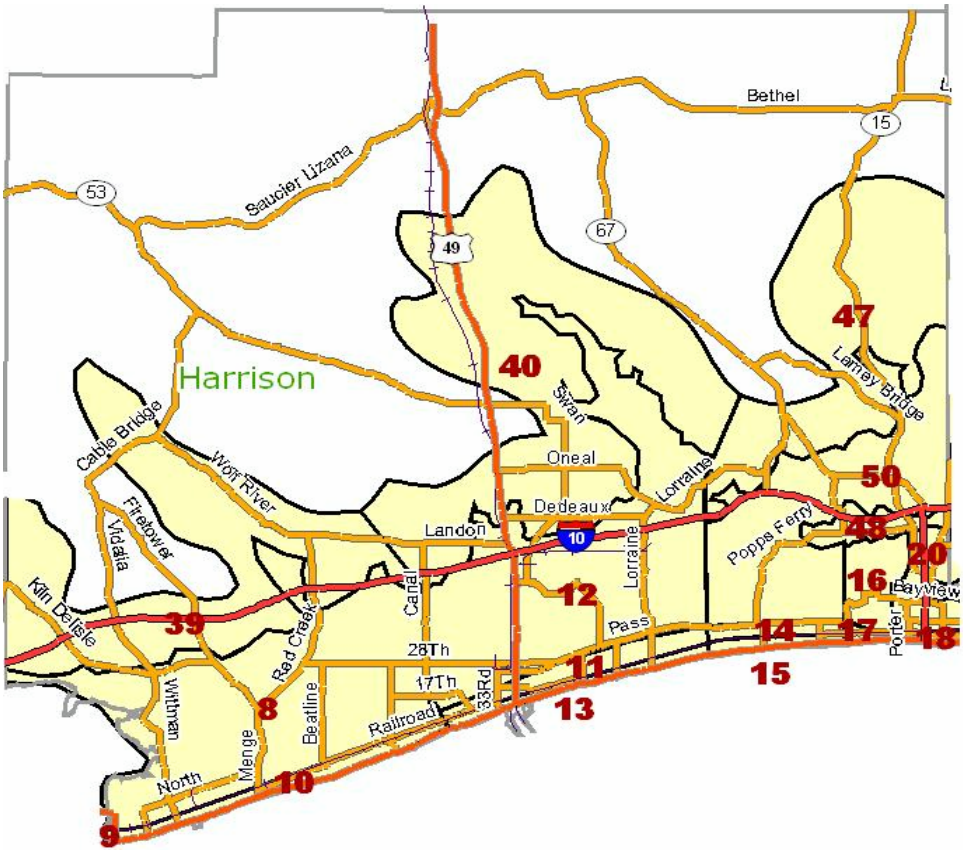

Figure 1-6. Sub-units for Planning Unit Two

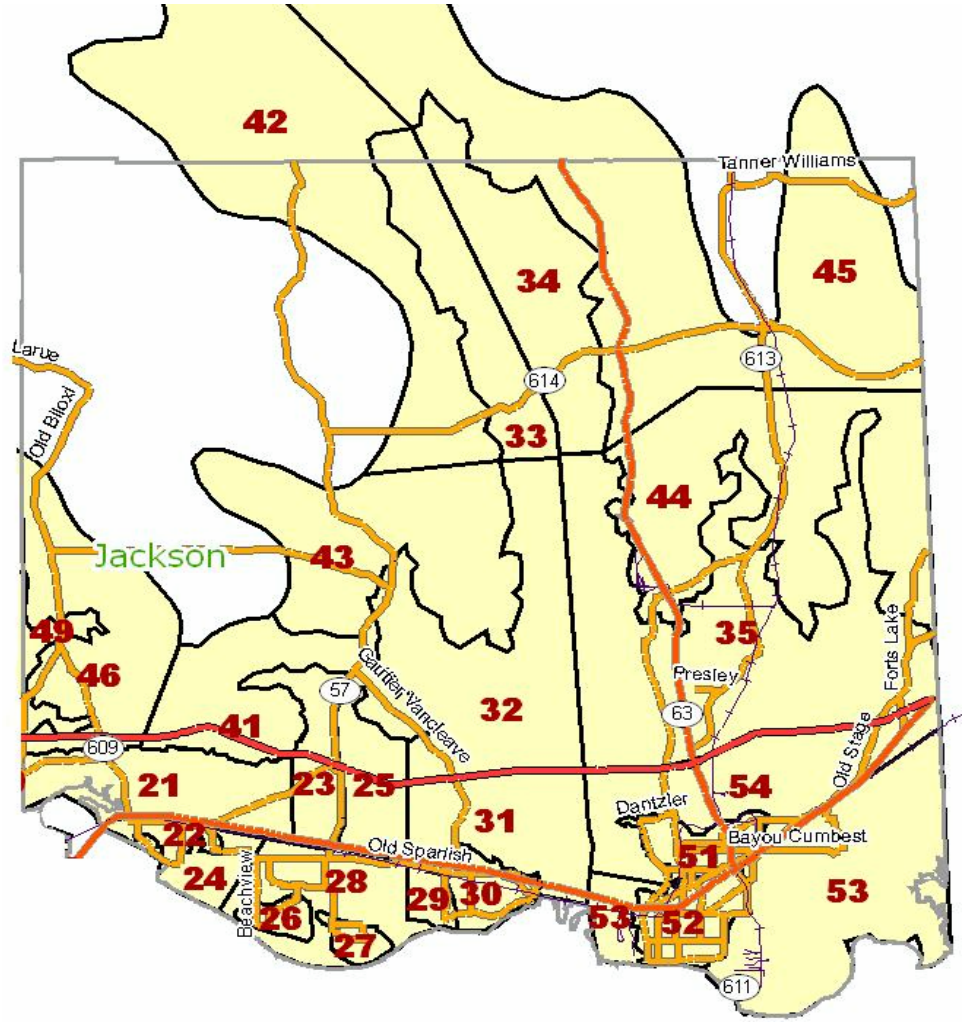

Figure 1-7. Sub units for Planning Unit Three

CHAPTER II. OVERVIEW OF ECONOMIC METHODOLOGY

This section describes the methodology for the evaluation of economic impacts of potential solutions for the Mississippi Gulf Coast under the Mississippi Coastal Improvements Program (MsCIP) Comprehensive Report. It is intended to be an outline of the process used to determine the economic impacts that are fully detailed throughout this appendix and in the main report. The methodology was developed to seamlessly fit into the six step planning process and current Corps guidance. The six step planning process, as defined by the Engineering Regulation (ER) 1105-2-100; Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (U.S. Water Resources Council 1983), referred to as the P&G, is:

1/ Identify Problems and Opportunities
2/ Inventory and Forecast Conditions
3/ Develop Alternatives
4/ Evaluate Alternatives
5/ Compare Alternatives
6/ Select the Recommended Plan

The Mississippi Gulf Coast is a complex system that is made up of a diverse blend of ecological and human habitats. Given those complexities, a fluid and flexible process was needed to evaluate and aggregate the benefits of potential measures and measures. The process incorporates data collection, forecasting techniques, scenario planning, cost effective evaluation using state of the art modeling techniques, and the communication of both benefits and risks associated with potential measures and measures. Figure 2-1 outlines the process used for this analysis.

The first step in the process was to delineate the study area. The overarching study area, as defined by Congress, is the three coastal counties in Mississippi; Hancock, Harrison and Jackson from west to east respectively. For purposes of system wide evaluation and aggregating benefits, the study area was divided into four planning zones, three planning units, and fifty-four sub-planning units. These are described in more detail in the following section.

Once the planning zones, planning units, and planning sub-units were identified, the next step was inventorying the economic, social, and environmental characteristics of the area. Data from Local, State, and Federal government agencies was utilized to determine the Historic (Pre-Hurricane Katrina) Condition, including data from the U.S. Census Bureau, the Federal Emergency Management Agency (FEMA), U.S. Fish and Wildlife, the Mississippi Emergency Management Agency (MEMA), the Mississippi Governor's Recovery Office, County Tax Assessors, previously conducted Corps of Engineers studies conducted in the area, and other valuable data sources. Historic data included economic structures (structures, content, and critical infrastructure), social and regional indicators (population, income, and employment), topographic and hydrologic characteristics, acreage of habitat, and etc.

With the historic data serving as a foundation, the next step was to determine the impacts of surge inundation from Hurricane Katrina. The team developed an inventorying methodology that was a combination of sampling and field verification. Every street within the fifty-four planning sub-units was driven over the course of four months from June to October, 2006, for purposes of determining the existing (Post-Hurricane Katrina) conditions and characteristics of structures. The findings of this work were put into a structure database that included over 200,000 tax parcels, 138,000 of which contained structures. Hydrologic programming was used to evaluate the surge inundation of each

planning sub-unit and a combination of Geographical Information System (GIS) data and ground truthing was used for habitat evaluation.

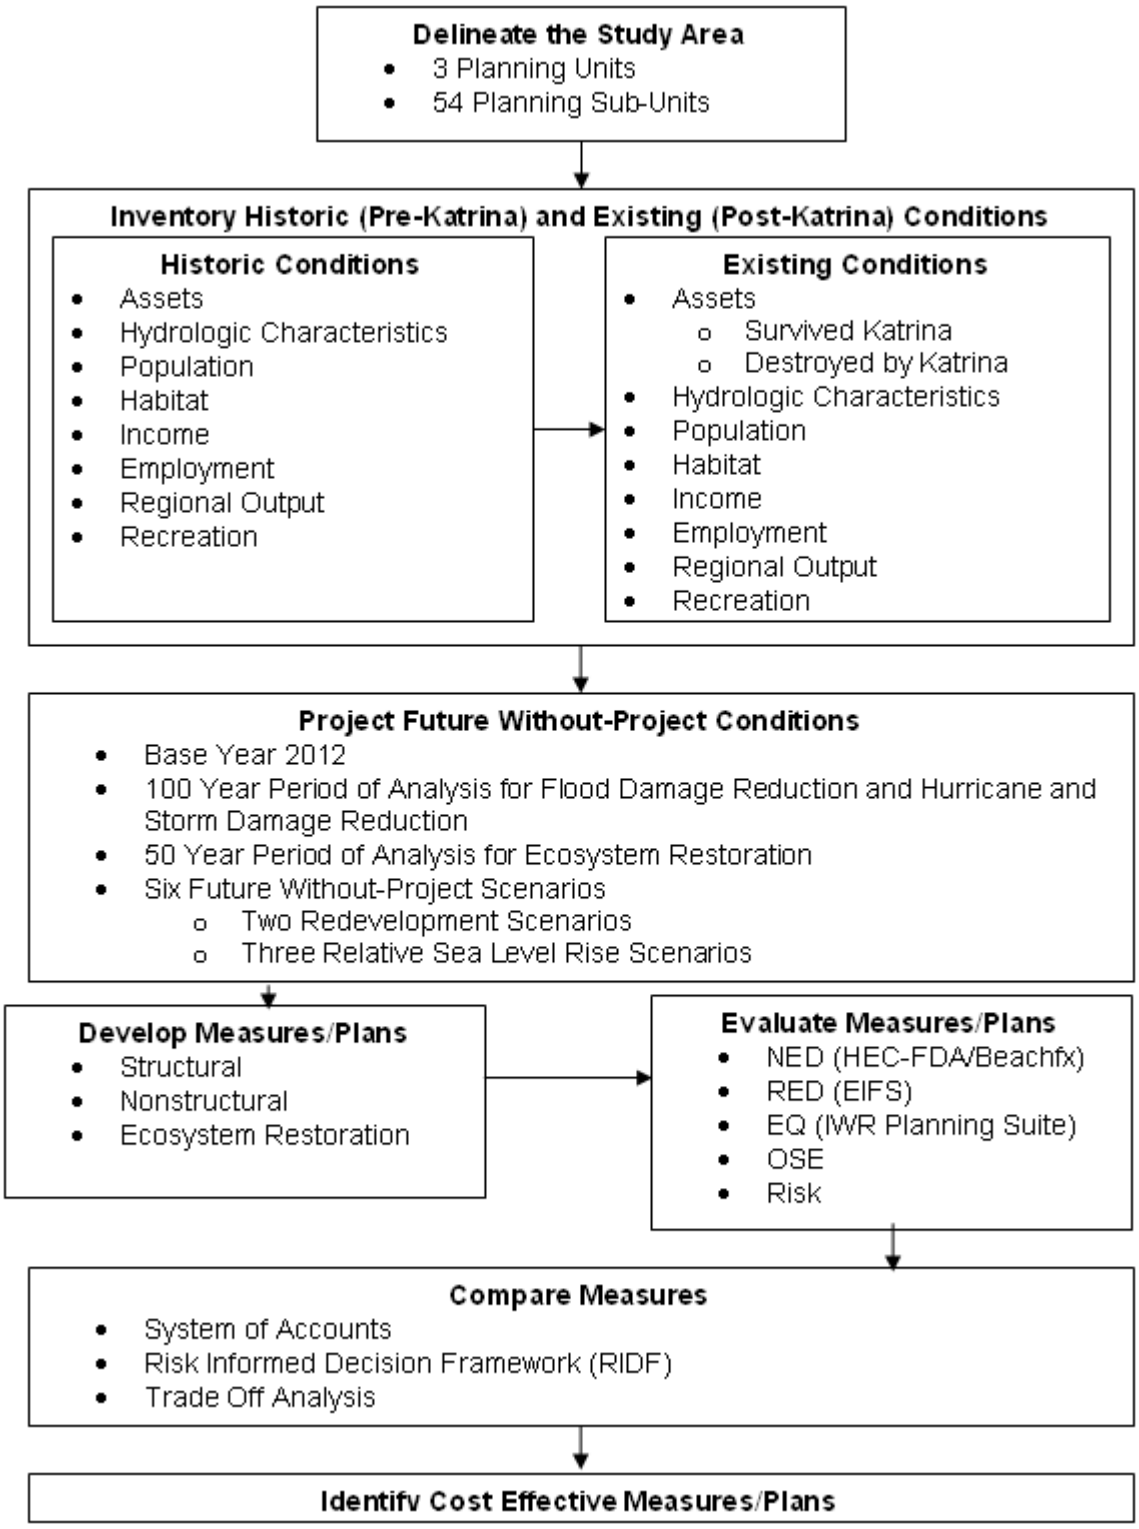

Figure 2-1. Overview of Economic Methodology

Six future without-project scenarios were developed, based on the existing condition characteristics, for the evaluation of future without-project conditions. In order to address sensitivity issues, the six scenarios were initially evaluated over a 100-year period of analysis from the base year 2012 (2012–2111) and using the FY08 federal discount rate of four-and-seven-eighths (4.875) percent. The six future scenarios include two redevelopment scenarios (residential and mixed-residential and commercial) and three relative sea level rise scenarios (existing, moderate, and high relative sea level rise) for a total of six different future scenarios. Scenario one is a residential redevelopment with no relative sea level rise over the 100-year period of analysis, scenario two is a mixed residential and commercial redevelopment with no relative sea level rise, scenario three is a residential redevelopment with a maximum relative sea level rise depending on location of 2.0-feet over the period of analysis, scenario four is a mixed residential and commercial redevelopment and a maximum relative sea level rise of a 2.0-foot, scenario five is a residential redevelopment with a relative sea level rise depending on location of 3.4-feet, and scenario six is a mixed residential and commercial redevelopment with a maximum relative sea level rise depending on location of 3.4-feet. All plans recommended for construction in the Comprehensive Plan were adjusted to a 50-year period of analysis per Corps Policy. The detailed evaluation of these scenarios is outlined below in the Future Without-Project section, and a technical description of the calculation of relative sea level can be found in the engineering appendix.

The next step, identified as step three in the planning process, was to develop measures that relate to the planning objectives for this study, which are detailed in section 2.3 of this document. An measure is something that can be implemented to directly address a problem within the study area. Some examples of measures include levees and acquisitions for flood damage reduction, beach and dune construction for flood damage reduction and ecosystem restoration, excavation and planting of native species for ecosystem restoration. These measures can be stand alone or may be able to be combined like a system.

For the Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan Report, multiple measures were developed under structural, nonstructural, and ecosystem restoration categories. The project delivery team applied a screening process based on engineering, environmental, and economic feasibility to narrow the list of viable measures. The full list of measures and how they were screened can be found in the MsCIP Comprehensive Plan Main Report.

The result of the screening was a list of measures that were fully evaluated as compared to the future without-project conditions. These measures were evaluated using the four systems of accounts, outlined in ER 1105-2-100, which include National Economic Development (NED) benefits, Regional Economic Development (RED) benefits, Environmental Quality benefits, and Other Social Effects (OSE). Evaluations of the various metrics that make up these four accounts were conducted using multiple economic programs, expert opinion, and other sources where available. The main economic programs used for the evaluation of measures include the Corps of Engineers Flood Inventory Tool (CEFIT), the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) program, the Beach-FX program, the Institute for Water Resources (IWR) Planning Suite, and the Economic Impact Forecasting System (EIFS). Outputs from these programs were carried forward for the comparison of the measures.

The final two steps of the process include a comparison of measures/plans and the identification of cost effective plans. A comparison of the evaluated measures was conducted using the System of Accounts (SOA) table and the Risk Informed Decision Framework (RIDF) process developed specifically for the MsCIP and LaCPR studies. Detailed descriptions of these two comparison methods and a list of tentatively-selected plan features can be found in Chapter Eight of this appendix and in the main report.

CHAPTER III. MODELING EFFORTS

3.1 Corps of Engineers Flood Inventory Tool (CEFIT)

3.1.1 Program Overview

The Corps of Engineers Flood Inventory Tool (CEFIT) program allows users to calculate replacement estimates for a variety of structures and replacement cost of commercial inventory. The CEFIT program is a proprietary program produced by Marshall and Swift in coordination with the Institute for Water Resources (IWR). The program consists of two components: a Residential Estimator component and a Commercial Contents Inventory component. The program allows for user inputs to define the type of structure that is being evaluated and provides outputs based on observed data collected by Marshall & Swift.

- Residential Estimator

The Residential Estimator component is a program that allows the user to calculate replacement cost for a variety of structures. It will calculate the depreciated replacement cost for single family residential, schools, and churches.

It has a variety of inputs that allow for a realistic estimate of depreciated replacement cost. It incorporates the location of the structure (by zip code), age, square footage, quality of construction, exterior wall material, roof type etc. All of these inputs increase the accuracy in gauging a correct estimate. The required inputs are location, age, square footage, quality of construction, and exterior wall material. Residential Estimator allows you to input your own depreciation factor or it allows the user to use program defined depreciated replacement factors based on data collection efforts for the defined area and other inputs.

The outputs for the Residential Estimator include a list of the inputs, total replacement cost of a new structure, depreciation on the structure due to age and quality, and the total depreciated replacement cost for the structure. Age and quality are the most influential factors in determining the amount of depreciation.

- Commercial Contents Inventory (CCI)

The Commercial Contents Inventory component is a program that allows the user to calculate depreciated replacement cost for inventory and equipment for various businesses. This program will calculate the depreciated replacement cost for a variety of business types. There are over 975 industry categories and 12 sales-size groupings.

There are 4 required inputs for CCI. They include: the sic code for primary and secondary operation, projected annual revenue for upcoming year, square footage of occupied building or portion of occupied building, and the number of full and part-time employees. CCI also has an input for the number of production shifts. However, the users manual recommend that the user should leave the production shifts at 1.

CCI has built in checkpoint procedures when it appears that certain inputs are outside the bounds of typical industry experience. When this happens inputs will be highlighted in red. The program also notes that it does not capture the value of leased or rented equipment. The program only captures the value on solely owned property and equipment.

The program recommends, for accurate results, to use current information, search for the closet sic code for the specific business type, use company specific data for optional items, and modify the quality and density level of equipment as appropriate.

The program returns three output values. It returns an inventory replacement value, an industry-norm equipment replacement value, and a company specific equipment replacement value. All of these values are depreciated replacement costs. The accuracy of the company specific depreciated replacement cost depends on the confidence level of input values.

3.1.2 Extent of Use

Where available, data from field interviews was utilized in estimating depreciated replacement cost for structure and content values. This was done by comparing tax data to data that was collected in the field and applying comparison percentages to different structure types. A detailed explanation of this process can be found below in chapter IV.

For those structure types, such as municipal and commercial and industrial structures, the CEFT program was employed for the estimation of depreciated replacement cost of structures and their contents. Specifically, the CEFIT program was used to estimate depreciated replacement cost of public structures and their contents, such as schools and churches, as well as to estimate the value of inventory within commercial and industrial structures. Data used as input for the program came from a variety of sources including field interviews of businesses, available financial statements of publicly traded companies, and existing data from previous Corps of Engineers studies. Outputs from the program were incorporated into the structure database described in detail in a later section of this appendix, and ultimately incorporated as inputs into the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) and Beach-FX programs for evaluation of damages and damages reduced.

3.1.3 Uncertainty

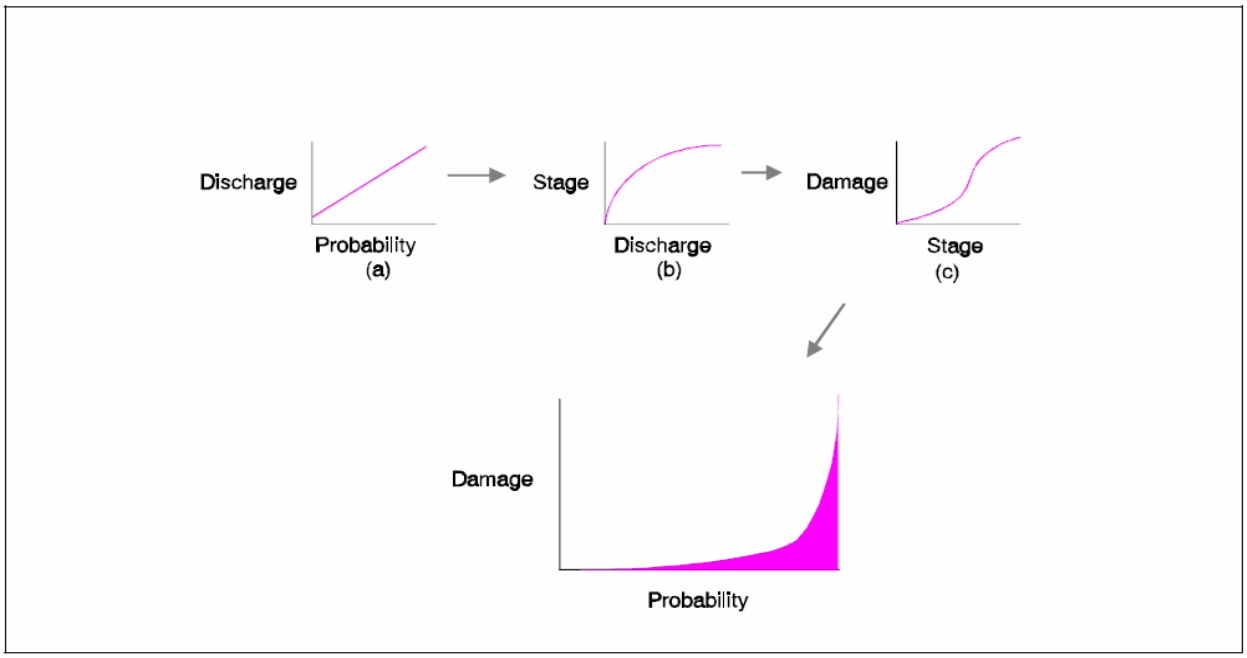
The CEFIT program does not contain a direct mechanism for addressing any uncertainty that exists in the estimation of the program's outputs. Since the output values, which include the depreciated replacement cost of schools and churches and of commercial and industrial structures, of the CEFIT program are an input for the HEC-FDA and Beach-FX programs, uncertainty is addressed within those program frameworks. Both programs allow you to input the uncertainty around the depreciated replacement cost of the structure and inventory values derived by the CEFIT program. The programs account for two standard deviations of uncertainty, or approximately the ninety-five percent confidence level. A detailed description of how the HEC-FDA and Beach-FX programs address uncertainty regarding these and other variables is described below in greater detail.

3.2 Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA)

3.2.1 Program Overview

The Hydrologic Engineering Center's-Flood Damage Analysis (HEC-FDA) program is the standard analytical tool for calculating equivalent annual damages (EAD) from flood inundation. As per the user's manual, the HEC-FDA program "Provides the capability to perform an integrated hydrologic engineering and economic analysis during the formulation and evaluation of flood damage reduction plans. The program follows functional elements of a study involving coordinated study layout and configuration, hydrologic engineering analyses, economic analyses, and plan formulation and

evaluation…the procedures are consistent with federal and Corps of Engineers policy regulations (ER-1105-2-100 and ER 1105-2-101)."



"Both economic flood damage and hydrologic engineering analyses are performed using a consistent study configuration (streams, damage reaches, plans, and analysis years). Two types of evaluations are available: analysis of damage and project performance by analysis year: and equivalent annual damage. Many Output tables and plots are used for reporting results. Computations and display of results are consistent with technical procedures described in EM 1110-2-1619."

The steps for evaluation using HEC-FDA are:

- Define Study Parameters
    - Study Stream(s) – defines the source of the water
    - Analysis Years - defines the base year and most likely future year
    - Survey Year – the year the data was initially collected
    - Update Year - allows for an update of data in the future
- Define Damage Reaches (Planning sub-units)
    - Reach Name – the limits of an area that share hydrologic and economic similarities
    - Beginning and Ending stations – the start and finish points of a reach
    - Index Location – a point between the beginning and ending stations of a reach where the greatest confidence in data is located for that reach (e.g. At a stream gage location)
- Define Plans
    - Existing Condition – typically the defined study area at the point in time the data was collected
    - Without-Project Condition – defines the study area with the assumptions made regarding the hydrologic and economic characteristics expected in the future if nothing were to be done
    - With-Project Conditions – defines each of the potential measures that could be implemented and how it acts (reduces damages) as compared to the without-project condition
- Enter Hydrologic Data
    - Water Surface Profile
    - Stage-Discharge Functions
    - Exceedance-Probability Functions
- Enter Economic Data
    - Structure Inventory Data – compiled database that includes structure characteristics such as location, structure and content value, first floor elevation, etc.
    - Depth Damage Relationships – defined relationships between the depth of water and the damage to each of the structures and their respective contents

- Assign Structure Inventories to Plans – each plan has its own specific structure inventory that is defined specifically for that plan and attributed to that plan
- Compute Aggregated Stage Damage with Uncertainty and Equivalent Annual Damages – this is the first computational step in the HEC-FDA model. It evaluates the damage at the various stages of the stage frequency curves and determines the damages attributed to each of the stage intervals. This step can be computed with or without uncertainty.
- Evaluation of Plans by Analysis Years – evaluates a plan and its performance reaches based on target standards defined for the without project conditions for the study. These standards are based on the residual damages associated with a specific exceedance probability event.
- Equivalent Annual Damage Analysis – computes the equivalent annual damages for each plan based on the pre-defined period of analysis years (e.g. 100-years) and the desired discount rate (e.g. 4.875-percent). Figure 3.2-1 shows the traditional EAD computation process.

EM 1110-2-1619
1 Aug 96

Source: Engineering Manual (EM) 1110-2-1619

Figure 3.2-1. Illustration of transformation for traditional equivalent annual damage computation

3.2.2 Depth Damage Relationships

The depth damage relationships used for the HEC-FDA analysis are based on expert elicitation and observation of damages from flood events. Generic curves for residential one-story and two-story structures and their contents are from *Corps of Engineers Economic Guidance Memorandum (EGM) 01-03, Generic Depth Damage Relationships*. Commercial, municipal, and mobile home structure and content curves are from the July 1997 final Report entitled *Depth-Damaged Relationships for Structures, Contents, and Vehicles and Content-To-Structure Value Ratios (CSVR) in Support of the Lower Atchafalaya Reevaluation and Morganza to the Gulf, Louisiana Feasibility Studies* prepared for New Orleans District Corps of Engineers. Addendum A to this appendix describes the HEC-FDA damage curves in detail.

3.2.3 Extent of Use

For the MsCIP Comprehensive Plan Report, the HEC-FDA model was used to evaluate the without-project flood damages of the study area and the respective damages reduced of various measures in the coastal and inland planning zones. The use of this model for the MsCIP Comprehensive Plan Report is slightly different than the typical riverine application of the model, but it is still an appropriate tool for the evaluation of measures under MsCIP. The Hydrologic Engineering Center (HEC) made several modifications to the model specifically for this study. Both modifications were with respect to the uncertainty bounds around the stage frequency curves and the first floor elevations of structures.

3.2.4 Uncertainty

The HEC-FDA model allows for the quantification of uncertainty pertaining to hydrologic characteristics, such as the exceedance probability functions, and economic characteristics such as first floor elevation, structure value, content value, and depth-damage relationships. Uncertainty regarding these parameters, and their effect on EAD, are captured by using Monte Carlo simulation. Monte Carlo simulation samples the parameters from a range, typically two standard deviations, and incorporates the potential variance in the values that may occur in the real world.

3.3 Beach-FX

3.3.1 Program Overview

Beach-FX is an engineering-economic program that simulates beach response over time, as storms, natural recovery, and management methods alter the beach profile. The model estimates expected structural damages expressed as losses due to flooding, erosion and waves. It is an event-based, data-driven Monte Carlo simulation program. This structure has been used successfully in the past in a large number of U.S. Corps of Engineers (USACE) studies.

The program is an event-driven life-cycle Monte Carlo simulation program. A shore protection project life cycle (e.g. 100-years) is simulated by determining the beach and structure response to a set of storms (the events driving the process). The associated damages are determined for each structure that is programmed. This simulation is repeated for many different sets of storms, and the results averaged. Input data to the program is stored in databases, and, wherever possible, information needed to localize, parameterize, and modify program behavior is also stored as data (data-driven programming).

The program simulates beach response over time as storms, natural recovery, and management methods alter the beach profile. Events of interest (storms, beach nourishment) take place at calculated times. As each event takes place, the program simulates the physical and economic responses associated with that event. Structural damages include losses due to flooding, erosion, and wave impact. Simplified beach profiles, as defined by key data points, are tracked as the beach profile evolves over time.

The program makes use of a Shoreline Response Database (SRD). The SRD is a pre-generated set of beach profile responses to storms, for a range of storms and profiles. The program uses “plausible storms”, based on historic storms, as initiating events. The procedure for developing plausible storms is described in Appendix A. The shoreline modification due to a storm is determined through use of a shoreline response program, in this case SBeach, a cross-shore storm response program developed by the Waterways Experiment Station (WES) of the Corps. The SRD contains information on the input (pre-storm) profile, the storm, and the response (post-storm) profile, for

many combinations of storms and pre-storm profiles. The Monte Carlo simulation program then reads information from the SRD as needed to determine shoreline change following a storm event.

As each storm is processed, the shoreline response is determined, and a post-storm beach configuration is calculated, as well as profiles of maximum water level, wave height, and erosion during the storm. This information is used to determine economic damages, based on empirical curves (damage functions) relating the percentage loss of value of structure and contents to "damage-driving parameters" calculated from the aforementioned profiles and characteristics of the structure. The nature of the data used by the program is shown in Figure 3.3.1.

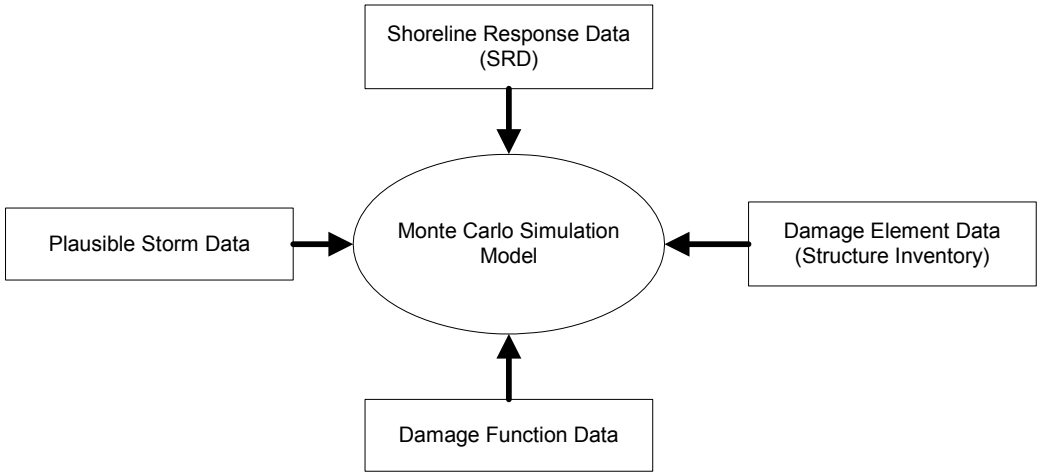


Figure 3.3-1. Data used for Beach-FX Program

3.3.2 Depth Damage Functions

Depth damage functions used within the Beach-FX simulations are based on expert elicitation and are broken into several damage categories. These damage categories include inundation damages, wave's damage, wave run-up (wave set-up) damages, and erosion damages. Addendum B to this appendix is an abstract of how the damage functions were developed and Addendum C describes in detail the damage functions used for Beach-FX.

3.3.3 Extent of Use

For the MsCIP Comprehensive Plan Report, the Beach-FX program was set up to be used to evaluate without-project damages and damages reduced for commercial structures that are physical located south (Gulf Side) of the major roadways in the three planning units. Those structures north of the major roadways in each of the planning units are evaluated using HEC-FDA (see previous section). Each of the beach and dune placement measures, described in detail later in this appendix, were evaluated against two future without-project scenarios: 1/ a future scenario with n expected relative sea level rise of 2.0-feet and 2/ a future scenario with a with an expected relative sea level rise of 3.4-feet. Section 6.2 of this appendix describes the Beach-FX evaluation in greater detail.

3.3.4 Uncertainty

The complexities of the combined engineering-economic problem of risk-based analysis, in which there are uncertainties associated with the physical performance of systems and the economic consequences of that performance, are typically addressed through the use of Monte Carlo

simulation techniques. Monte Carlo simulation is particularly useful for physically based real-world problems, where the results of the simulation can be tested against historical and reasonable behaviors.

Beach-FX uses Monte Carlo simulation to sample variable values within a range in order to capture uncertainty. Variables such as structure value, content and inventory, first floor elevation, and days to rebuild the structure when it is destroyed are given an upper and lower limit, which the simulation selects from each time a lifecycle is run.

3.4 Institute for Water Resources (IWR) Planning Suite

3.4.1 Program Overview

The US Army Corps of Engineers Institute for Water Resources (IWR) has developed IWR-PLAN Decision Support Software to assist with the formulation and comparison of alternative plans. While IWR-PLAN was initially developed to assist with environmental restoration and watershed planning studies, the program can be useful in planning studies addressing a wide variety of problems. IWR-PLAN can assist with plan formulation by combining solutions to planning problems and calculating the additive effects of each combination, or "plan." IWR-PLAN can assist with plan comparison by conducting cost effectiveness and incremental cost analyses, identifying the plans which are the best financial investments and displaying the effects of each on a range of decision variables.

IWR-PLAN builds upon the basic plan formulation and comparison framework of the DOS program ECO-EASY: Cost Effectiveness and Incremental Cost Analyses for Environmental Planning developed within the Corps Evaluation of Environmental Investments Research Program. The IWR-PLAN system transforms ECO-EASY to a Windows95 or Windows NT operating environment while adding new functions. Development of IWR-PLAN has been carried out within the Corps Decision Support Technologies Research Program, conducted at IWR. The Corps of Engineers and the Social Sciences Institute of the Natural Resources Conservation Service cosponsor IWR-PLAN development. To aid new users along the IWR-PLAN learning curve, a checklist of steps for applying the software is included under the section Getting Started.

IWR-PLAN takes user-defined solutions to planning problems and externally-generated estimates of each solution's effects and can formulate all possible combinations of those solutions, considering user-defined relationships between solutions. IWR-PLAN will then identify which combinations are the best financial investments through cost effectiveness and incremental cost analyses. Each combination of solutions is an alternative plan. If alternative plans have already been formulated outside IWR-PLAN, the user can bypass the routine for building combinations and still use IWR-PLAN to assist in identifying which plans are the best investments.

IWR-PLAN includes many new functions. An important one is that IWR-PLAN will keep track of the effects on up to ten user-defined variables. This makes IWR-PLAN a useful tool in watershed scale studies where there are likely to be a wide range of effects under consideration.

Other new functions include the ability to set constraints for all variables, to define derived variables (weighted combinations of other variables), to conduct sensitivity analysis, to examine different scenarios with different assumptions from one set of input data, to make comparisons across different scenarios, to track user defined "plans of interest", to export all IWR-PLAN data with direct links to other software, to view results through a variety of reporting and graphing measures, and to access on-screen help.

IWR-PLAN’s context-sensitive on-screen help system is available on each screen to define terms and explain how to use the screen's functions. This Online help, together with the Getting Started

checklist and accompanying operating instructions, should provide enough information to operate IWR-PLAN successfully. Additional background information is provided by the procedures manual Cost Effectiveness and Incremental Cost Analyses published by IWR in 1995 (IWR Report 95-R-1). This manual is recommended reading - especially for new users without previous ECO-EASY experience. The manual is available by download from the section "Current Reports Online" on IWR's home page.

3.4.2 Extent of Use

IWR Plan was used to conduct a cost effectiveness analysis for each of the measures and alternatives that were formulated for ecosystem restoration (see Chapter VI). The analyses followed the methodologies established in the US Army Corps of Engineers Institute for Water Resources publications, Evaluation of Environmental Investment Procedures Manual, Interim: Cost Effectiveness and Incremental Analyses, May 1995, IWR Report #95-R-1 and Cost Effectiveness Analysis for Environmental Measuring: Nine Easy Steps, October 1994, IWR Report 94-PS-2. The nine steps outline in the cited IWR report have become the standard practice for identifying what are known as “Best Buy” ecosystem restoration measures, or those measures that yield the greatest ‘bang for the buck’ at various levels of output.

The IWR Measure model was developed based on these nine steps and is the preferred Corps of Engineers model for the evaluation for ecosystem restoration measures. For the MsCIP Comprehensive Plan Report, Congressional Authority stated, "…but shall not perform an incremental benefit-cost analysis to identify the recommended project…." Following this authorization, only the first five steps of the nine easy steps, which are bolded below, were used in the IWR Plan evaluation, resulting in the identification of cost effective plans for restoration purposes. The nine steps are:

- Formulation of combinations:
  Step 1 - Display Outputs and Costs
  Step 2 – Identify Combinable Management Measures
  Step 3 – Calculate Outputs and Costs
- Cost Effective Analysis:
  Step 4 – Eliminate Economically Inefficient Solutions
  Step 5 – Eliminate Economically Ineffective Solutions
- Development of Incremental Cost Curve
  Step 6 – Calculate average costs
  Step 7 – Recalculate average costs for additional output
- Incremental Cost Analysis:
  Step 8 – Calculate incremental costs
  Step 9 – Compare successive outputs and incremental costs

3.4.3 Uncertainty

Uncertainty is a factor in any number manipulation program. Cost variability and output variability can be incorporated into the IWR Plan program using sensitivity calculations. Sensitivity can be calculated by using either variable sensitivity or solution sensitivity. A uniform coefficient can be applied to all variables or selected variables.

Variable sensitivity calculates high and low variable values using a uniform coefficient. This creates results for a range for the variable value. Custom sensitivity can be applied.

The high and low values entered for solution sensitivity are uniform coefficients used for computing the high and low values for the selected solution combination. This creates a value range result for that solution.

3.5 Economic Impact Forecasting Systems (EIFS)

3.5.1 Program Overview

The Economic Impact Forecast Systems (EIFS) was originally developed by the U.S. Army Corps of Engineers Construction Engineering Research Laboratory (USACERL) in 1975 to efficiently identify and address the regional economic effects of proposed military actions. EIFS is a web-based program and information system that provides regional economic analyses to planners and analysts. The program was developed to provide socioeconomic impact assessment, necessitated by the passage of the National Environmental Policy Act (NEPA) in 1969, which requires federal agencies to consider the impacts of an action on the "human environment" before decisions are made or an action is taken. This process is intended to help public officials make better decisions that are based on an understanding of environmental consequences and take actions that protect, restore, and enhance the human environment.

The EIFS program draws information from a tailored socioeconomic database for any county (or multi-county area) in the United States, estimating the changes associated with any project proposal, as defined by the user. EIFS database consists of data gathered from economic analyses, including Census of Agriculture, the Bureau of Economic Analysis, and County Business Patterns. The EIFS program requires basic input data regarding the action being studied: the dollar amounts of associated construction, number of military and civilian employees and their average salaries. Once these inputs are ascertained, the local multi-county region of influence (ROI) can be defined. Given the inputs for a particular project proposal, EIFS through a series of algorithm that are based on regional economic theory will assess potential impacts on four elements of a local economy: business volume, employment, personal income, and population. In short the program provides flexibility for the evaluation of measure scenarios and "what if" games at minimal expense.

3.5.2 Extent of Use

The EIFS program was used to evaluate the Regional Economic Development (RED) of proposed measures and plans. The conclusion that EIFS makes is that it predicts resultant changes in total personal income, total employment, and total sales by local businesses, and total population. Once these aggregate changes are predicted, EIFS provides analyses of historical trends in the defined ROI, and uses the Rational Threshold Level (RTV) and Forecast Significance of Impacts (FSI) profiles to develop significance criteria. Comparisons of projected change are then easily compared to the significance thresholds to produce conclusions. If insignificant impacts result, the analysis is complete. If significant impacts are indicated, a more detailed analysis will likely be required. In other words, because a projected change indicates that it would not be within the historic RTV range, it does not necessarily mean that it has a significant impact. It only means that a more detailed analysis is likely required to resolve this issue. The EIFS program, in combination with the RTV, has proven successful in determining socioeconomic impacts. The system meets the criteria for a good assessment program; theoretically sound and defensible, available for public review and scrutiny, and pragmatic in its application.

3.5.3 Uncertainty

The EIFS model incorporates uncertainty by using a Rational Threshold Value (RTV). Once model projections are obtained, the Rational Threshold Value profile allows the user to evaluate the significance of the impacts. This analytical tool reviews the historical trends for the defined region and develops measures of local historical fluctuations in sales volume, income, employment, and population. These evaluations identify the positive and negative changes within which a project can affect the local economy without creating a significant impact. The greatest historical changes define the boundaries that provide a basis for comparing an action's impact on the historical fluctuation in a particular area. Specifically, EIFS sets the boundaries by multiplying the maximum historical deviation of the following variables:

	Increase	**Decrease**
Sales Volume	x%	x%
Income	x%	x%
Employment	x%	x%
Population	x%	x%

The major strengths of the RTV are its specificity to the region under analysis and its basis on actual historical data for the region. The EIFS impact model, in combination with the RTV, has proven successful in addressing perceived socioeconomic impacts. The EIFS model and the RTV technique for measuring the intensity of impacts have been reviewed by economic experts and have been deemed theoretically sound.

CHAPTER IV. DATA COLLECTION METHODOLOGY

This section describes in detail the methodology implemented for the collection of data for the evaluation of National Economic Development (NED) benefits, Regional Economic Development (RED) benefits, Environmental Quality (EQ) benefits, and Other Social Effects (OSE). Data collection is a central element in the overall inventory and evaluation process. Hurricane Katrina hit the Mississippi Gulf Coast on August 29th, 2005 and caused significant damage to the environmental, human, and economic landscape of the area. The effects of this devastating event form the existing conditions for the MsCIP Comprehensive Plan and the basis to which the analysis of potential solutions were conducted and outlined in this appendix.

Due to limited time and the magnitude of the number of structures in the 40-foot NAVD88 surge inundation footprint, a hybrid field verification/sampling technique was developed for purposes of collecting structure data. Structure characteristics are crucial in the evaluation of risk and potential damage from surge events. The main structure data collected for this analysis was 1/ damage category, 2/ structure occupancy type, 3/ first floor elevation, 4/ structure value, 5/ content value, and 6/ whether or not the structure was significantly damaged by Hurricane Katrina. The ability to confidently obtain values for these data variables were the driving force in the development of the field verification methodology.

The first step in the field verification process was to obtain existing data from Local, State, and Federal government agencies as well as credible academic sources. For economic structure data, pre-Hurricane Katrina (2005) tax data for each of the planning units was obtained from Hancock, Harrison, and Jackson Counties, Mississippi. Next, utilizing GIS software, all of the tax parcels that fell within the 40-foot (NAVD-88) surge inundation footprint were identified, creating the maximum extent of parcels that would be identified that would be impacted by a surge analysis. This area is approximately 1,361 square miles or 100 square miles larger than the state of Rhode Island.

Next, a cluster sampling methodology was created and inventoried by driving every street within the inundation area. The sampling methodology was based upon the fact that construction along the Gulf Coast is very similar and that blocks, streets, and or subdivisions could be grouped together. While driving the area, the PDT members determined the grouping sizes based on observations in the field, and then defined typical structure characteristics for the grouping. For example, “A subdivision may be four streets and include approximately fifty structures. The subdivision may have two basic construction types, 1/ residential one-story and 2/ residential two-story, split approximately seventy-percent and thirty-percent respectively. Within the subdivision, the first floor elevation above ground of structures may range from four to six feet. The homes were built in the 1990’s so the construction is generally good in quality. Water was a factor in this area and approximately sixty percent of the homes in this area sustained significant inundation damage (50% or more damaged).” These observations were noted and input into the structure database for this area as the economic characteristics. The process was repeated over the course of six months from June through November, 2006. The end result was a database with economic data for over 200,000 tax parcels within the 40-foot NAVD88 inundation area.

Other sources of existing data were also identified for purposes of evaluating Environmental Quality, Regional Economic Development, and Other Social Effects. Data from Local, State, and Federal government agencies as well as reputable academic sources were utilized for data collection in these areas. The methodology used for the collection of data in this analysis is outline in Figure 4-1.

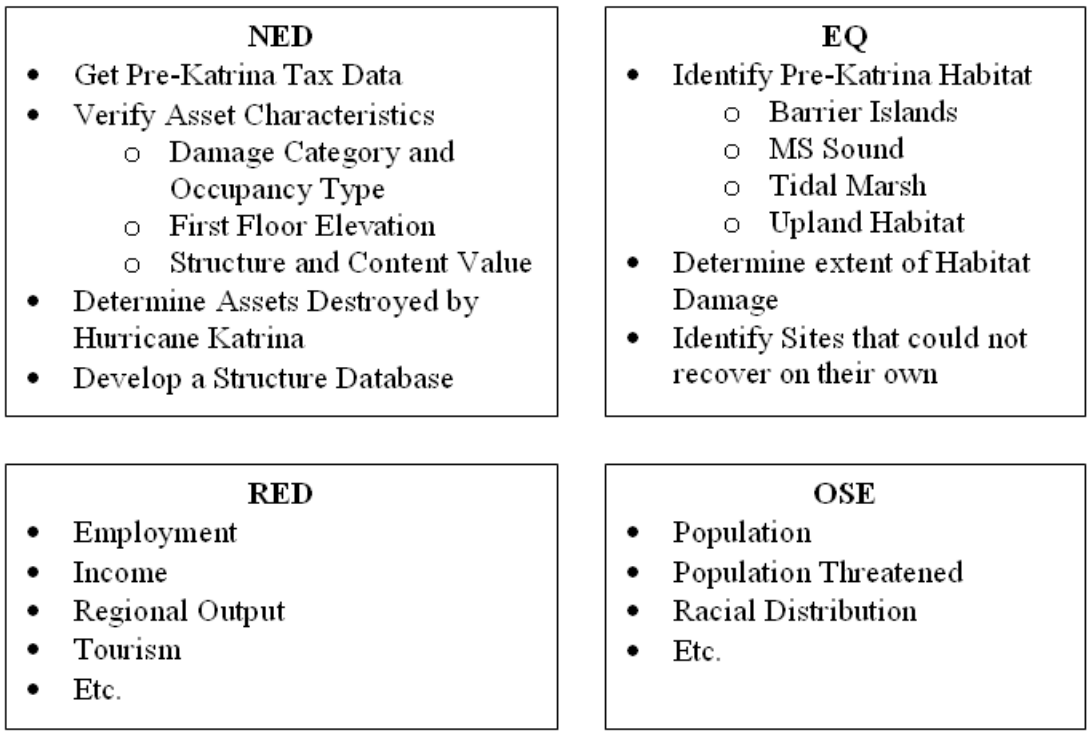

Figure 4-1. Overview of Economic Data Collection Methodology

4.1 Damage Categories

Damage categories are a means of initially categorizing the structures within the study area. This basic category is dictated primarily by general use of the structure. For this report, all structures fall within the categories of residential, commercial, municipal, and mobile home. A combination of tax data and field verification were used to determine the damage category for each structure.

4.2 Occupancy Types

Structures in each damage category were further subcategorized into structure occupancy types. The structure occupancy type allows for the combining of structures that have very similar characteristics such as construction material and depth-damage relationships. The residential damage category includes one-story and two-story single family residences. The commercial category includes: 1/ eating and recreation, 2/ groceries and gas stations, 3/ multi-family residences, 4/ repair and home use, 5/ retail and personal services, 6/ professional business, and 7/ warehouse and contractor services. The municipal category includes those structures which are generally non-taxable structures including federal, state, and local structures as well as churches. The Mobile Home category includes pre-manufactured single family residential housing that is not on a permanently fixed foundation (can be moved with relative ease). Table 4-1 provides a list of structures that fall into the various categories and occupancy types. Figures 4.2-1 through 4.2-14.

Table 4-1.
Structure Damage Categories and Occupancy Types

Damage Category	Occupancy Type	Structure Examples
COMMERCIAL	EAT	Restaurants, bars, and lounges
COMMERCIAL	MULT	Apartments, condos, multi-family
COMMERCIAL	REPA	Auto repair shops
COMMERCIAL	RETA	Retail, Laundromat, barber shop
COMMERCIAL	GROC	Grocery stores and gas stations
COMMERCIAL	WARE	Warehouses, light industry
COMMERCIAL	PROF	Hospitals, medical clinics, lawyer and professional offices
RESIDENTIAL	1-STORY	Single family dwellings with one story construction
RESIDENTIAL	2-STORY	Single family dwellings with two story construction
Mobile Homes	MOBHOME	Mobile Homes and other small metal structures
Municipal	PUBL	Municipal buildings, schools, police and fire stations

Figure 4.2-14. Example of a Municipal Fire Station

4.3 First Floor Elevations

First floor elevations were estimated using a two part approach. The first step was to estimate the ground elevation NAVD88 at the center point of each parcel using LIDAR data and a GIS program. The second part of the process was to estimate the finished floor elevation above the ground for each structure. The entire study area driven and estimates were made of the height above ground for each structure within a group or cluster. For example, “In neighborhood A, all on the structures were slab on grade and therefore the finished floor above ground for all the structures in that neighborhood were assigned a zero value. Thus, all structures in neighborhood A had a first floor elevation equal to the ground elevation.” The sum of the ground elevation plus the finished floor height above ground (ground + finished floor above ground = first floor elevation) was the first floor elevation NAVD88 for a given structure. Those first floor elevations were then attributed to the appropriate structure in the structure database.

Uncertainty pertaining to first floor elevation estimates exist for reasons ranging from human error to software rounding and uncertainty with regards to the precision of LIDAR data collection. Both the HEC-FDA and Beach-FX programs allow for the inclusion of uncertainty with regards to first floor elevation estimates. For this analysis, the field observed uncertainty pertaining to first floor elevations is 3.52-feet at one standard deviation.

Uncertainty was calculated by comparing surveyed first floor elevations to LIDAR plus field estimating technique. This was accomplished by the comparison of 3,000 structures (1,000 in each planning unit), or approximately a two-percent sample. Contractors working for the MOBILE DISTRICT shot accurate first floor elevations for those 3,000 structures and the PDT members compared the contractor values with the LIDAR plus field estimated values to calculate the one-

standard deviation uncertainty. This uncertainty was then used as an input into HEC-FDA and Beach-FX for the calculation of equivalent annual damages.

The 3.52-feet of uncertainty at one standard deviation are a significant uncertainty, and are commensurate of the time and scoping limitations placed on the MsCIP Comprehensive Effort. At approximately $25 per structure to acquire field shot first floor elevations, a cost of approximately $3,250,000 and an estimated time of two-and-a-half years would be needed to acquire the first floor elevation with the traditional confidence level of a feasibility level effort. A complete traditional survey of all of the first floor elevations within the MPI footprint is neither cost effective nor feasible with respect to timing constraints.

Even though the data shows a 3.52-foot uncertainty, it is believed that the first floor elevation data is more accurate than the distribution based on the two-percent sample suggests. Therefore a sensitivity analysis was conducted based on uncertainty used in previously conducted feasibility studies where costs and timing allowed for a complete traditional survey. This sensitivity analysis can be found below in Chapter VII of this appendix.

4.4 Structure Values

This section describes the estimation of structure values used as inputs for the calculation of equivalent annual damages. Typical Corps economic policy is to use an estimate of depreciated replacement cost for the value of a structure. Depreciated replacement cost was used for structures that were not destroyed by Hurricane Katrina, and full depreciated replacement cost was used for those structures that were expected to be rebuilt. The process for estimating depreciated replacement cost of structures was unique for the residential, commercial and industrial, and municipal categories. Where applicable, field observed and tax data was incorporated into the processes described in the following subsections. Where field and tax data gaps existed, Marshall and Swift proprietary software were used to estimate the value of structures.

4.4.1 Residential Structure Values

1) Tax data for all residential structures in the maximum probable intensity (MPI) inundation footprint area was collected from each county tax assessor. A sample for each residential category was provided to Savannah District (SAS) Real Estate Division.

2) Residential categories include:

a. Single family residences (SFR) - were categorized based on construction type (wood/slab, brick/pile, etc.) and floors (1, 2, or 3).

b. Multi-family residences (MFR)[1] - were categorized as town homes, duplexes, or triplexes and apartments were either 1 or 2 stories.

3) SAS Real Estate used Marshall and Swift software to determine the depreciated replacement cost of each residential structure within the sample and provided the estimates to the SAM Economic team.

[1] Multi-family residences (Duplexes, Triplexes, and Town homes) are given the commercial category name for depth damage purposes only, since they damage in a different way from single family residences even though they are still residential for discussion purposes.

Depreciated replacement cost estimates produced by the Marshall and Swift program were calculated using a number of inputs including:

- Square footage
- Number of stories
- Exterior wall materials e.g. masonry or wood
- Foundation
- Quality
- Age of structure

The most important input in determining the depreciated replacement cost of a structure is its age.

4) The Mobile District (SAM) Economic team compared the Marshall and Swift estimates to the pre-Hurricane Katrina tax assessed value of the sample and determined a depreciated replacement cost 'factor' by each category. Table 4-2 describes the depreciated replacement cost factors for the different types of residential structures.

Table 4-2.
Depreciated Replacement Factors by Occupancy Type Used for Residential Structures that Suffered Moderate to No Damage (Less than 50%) from Hurricane Katrina

Category Name	Type	Construction Type	Depreciated Replacement Factor (%)
Residential	Single Family Residence	Wood on Slab	81%
Residential	Single Family Residence	Masonry on Slab	88%
Residential	Single Family Residence	Wood on Piles	84%
Residential	Single Family Residence	Masonry on Piles	98%
Commercial[1]	Duplex	N/A	70%
Commercial[1]	Triplex	N/A	87%
Commercial[1]	Town Homes	N/A	70%
Commercial[1]	Apartments	N/A	100%

1 Multi-family residences (Duplexes, Triplexes, and Town homes) are given the commercial category name for depth damage purposes only, since they damage in a different way from single family residences even though they are still residential for discussion purposes.

5) The depreciated replacement cost factors described in table 4-2 were then applied to all the residential structures in the corresponding category by multiplying that percentage times the tax assessed value for the structure. For example, if the tax value for a single family wood on slab residence was $100,000, then the depreciated replacement value for the structure was $81,000 ($100,0000 x 81% = $81,000).

6) If the structure was sustained significant damage from Hurricane Katrina (50% or more destroyed), full depreciated replacement costs were given to that structure. The CEFIT program was used to determine the depreciated replacement cost of residential structures. The CEFIT model estimates depreciated replacement cost value based on the parameters mentioned above, such as square footage and age of structure. The estimation of depreciated replacement cost values was conducted by taking an average of values produced from a range of values in each parameter. For example, a range of 1,000, 1,250, 1,500, 1,750, 2,000, and 2,500 square feet was used when defining the size; a range of fair-to-good, good, good-to-very good, very good, very-good to excellent

and excellent were used for quality and condition; etc. Table 4-3 shows the averages from the sample range by residential category.

Table 4-3.
Depreciated Replacement Cost Values for Residential Structures Used for Residential Structures that Suffered Significant Damage (50% or more) from Hurricane Katrina

Category Name	Construction Type	Number of Floors	Depreciated Replacement Cost ($)
Residential	Wood	1	$119,400
Residential	Wood	2	$148,702
Residential	Masonry	1	$193,475
Residential	Masonry	2	$176,079

1/ Based on estimates obtained from the CEFIT program.

B. Commercial/Industrial:

1) Commercial structures were categorized by business type (fast food, grocery, restaurant, gas station, motel/hotel, etc).

2) SAS Real Estate used Marshall and Swift Estimator to determine the depreciated replacement cost of a typical structure in each category and provided the estimates to the SAM Economic team which was then applied to all structures in that category. This was compared with the Pre-Katrina tax records and a depreciated replacement cost factor was then found for each business category. The factor percentages for commercial structures were high in comparison with the norm of depreciated replacement costs. This is a result of deflated structure values before Hurricane Katrina and less recent tax data. Table 4-4 shows the depreciated replacement cost factors for various types of commercial structures. They were applied in the same way as the residential factors previously described.

Table 4-4.
Depreciated Replacement Factors by Occupancy Type Used for Residential Structures that Suffered Moderate to No Damage (Less than 50%) from Hurricane Katrina

Category Name	Type	Depreciated Replacement Factor (%)
Commercial	Airline Hanger	79%
Commercial	Bank	79%
Commercial	Casino (Small)	60%
Commercial	Casino (Medium)	88%
Commercial	Casino (Large)	100%
Commercial	Factory (Small)	80%
Commercial	Factory (Medium to Large)	100%
Commercial	Fast Food	92%
Commercial	Gas Station (Small)	83%
Commercial	Gas Station (Medium to Large)	95%
Commercial	Grocery (Small)	54%
Commercial	Grocery (Medium)	78%
Commercial	Grocery (Large)	100%

Table 4-4.
Depreciated Replacement Factors by Occupancy Type
Used for Residential Structures that Suffered Moderate to No Damage
(Less than 50%) from Hurricane Katrina (continued)

Category Name	Type	Depreciated Replacement Factor (%)
Commercial	Small Retail (Sore)	80%
Commercial	Large Retail	95%
Commercial	Hospital (Small)	71%
Commercial	Hospital (Medium to Large)	75%
Commercial	Laundromat	72%
Commercial	Lodge	70%
Commercial	Medical Clinic	80%
Commercial	Meeting Hall	55%
Commercial	Mini-Storage	88%
Commercial	Motel	100%
Commercial	Nursing Home	82%
Commercial	Office (Medical)	90%
Commercial	Quick Lube	94%
Commercial	Restaurant (Local)	80%
Commercial	Restaurant (National Chain)	96%
Commercial	Seafood Factory	100%
Commercial	Strip Mall (Small)	69%
Commercial	Strip Mall (Medium-Large)	100%
Commercial	Theater	100%
Commercial	Warehouse	69%
Commercial	Warehouse	100%

3) If the structure sustained significant damage from Hurricane Katrina (50% or more destroyed), full depreciated replacement costs were given to that structure. SAS Real Estate division estimated full depreciated replacement cost for the same business categories previously mentioned. Those depreciated replacement cost values were applied to the structures that were destroyed by Hurricane Katrina. Table 4-5 shows the depreciated replacement cost for the various commercial structure types.

Table 4-5.
Depreciated Replacement Cost Values for Residential Structures
Used for Residential Structures that Suffered Significant Damage
(50% or more) from Hurricane Katrina

Category Name	Type	Depreciated Replacement ($)
Commercial	Airline Hanger	$23,488
Commercial	Bank	$146,855
Commercial	Casino (Small)	$15,100,912
Commercial	Casino (Medium)	$63,289,595
Commercial	Casino (Large)	$176,994,638
Commercial	Factory (Small)	$454,045

Table 4-5.
Depreciated Replacement Cost Values for Residential Structures Used for Residential Structures that Suffered Significant Damage (50% or more) from Hurricane Katrina (continued)

Category Name	Type	Depreciated Replacement ($)
Commercial	Factory (Medium to Large)	$874,997
Commercial	Fast Food	$225,626
Commercial	Gas Station (Small)	$112,040
Commercial	Gas Station (Medium to Large)	$261,828
Commercial	Grocery (Small)	$580,453
Commercial	Grocery (Medium)	$1,609,533
Commercial	Grocery (Large)	$2,103,448
Commercial	Small Retail (Sore)	$319,779
Commercial	Large Retail	$3,535,050
Commercial	Hospital (Small)	$5,977,498
Commercial	Hospital (Medium to Large)	$8,445,952
Commercial	Laundromat	$72,224
Commercial	Lodge	$129,923
Commercial	Medical Clinic	$1,046,930
Commercial	Meeting Hall	$211,446
Commercial	Mini-Storage	$110,651
Commercial	Motel	$7,482,273
Commercial	Nursing Home	$123,606
Commercial	Office (Medical)	$350,235
Commercial	Quick Lube	$114,692
Commercial	Restaurant (Local)	$80,947
Commercial	Restaurant (National Chain)	$400,306
Commercial	Seafood Factory	$300,608
Commercial	Strip Mall (Small)	$319,779
Commercial	Strip Mall (Medium-Large)	$8,985,291
Commercial	Theater	$2,050,454
Commercial	Warehouse (Small)	$39,474
Commercial	Warehouse (Medium-Large)	$92,224

C. Municipal and Churches (Tax exempt):

1) No tax data existed for Municipal structures/Churches since they are tax exempt, therefore a depreciated cost factor could not be estimated for structures that fell into this category. Marshall and Swift software was used to estimate depreciated replacement cost for these structures.

2) Municipal structures/Churches were categorized as low, medium, and high based on size, number of floors, and other structure characteristics.

3) SAS Real Estate used Marshall and Swift software to determine the depreciated replacement cost of a typical structure in each category and provided the estimates to the SAM Economic team which were then applied to all structures in that category.

Estimates were calculated using a number of inputs including:

- Square footage
- Number of stories
- Exterior wall materials e.g. masonry or wood
- Foundation
- Quality
- Age of structure

The most important input in determining the depreciated replacement cost of a structure was its age. Table 4-6 shows the depreciated replacement costs for the various types of municipal structures.

Table 4-6.
Depreciated Replacement Factors by Occupancy Type

Category Name	Type	Depreciated Replacement Cost ($)
Municipal	Church (Small)	$126,125
Municipal	Church (Medium)	$990,116
Municipal	Church (Large)	$5,612,686
Municipal	Government and School (Small)	$462,712
Municipal	Government and School (Medium)	$523,404
Municipal	Government and School (Large)	$1,537,263

Uncertainty pertaining to structure value was estimated and put into the HEC-FDA and Beach-FX models as part of the process to calculate equivalent annual damages. Previous MOBILE DISTRICT feasibility studies estimated uncertainty of structure values between 10 and 15-percent. Since the nature of the sampling used for the MsCIP study was less rigorous than normal feasibility level efforts, a 25-percent uncertainty was used for structure values.

4.5 Content Values

This section describes the process used to estimate content values for residential, commercial and industrial, and municipal and church structures. Were available, data collected from field interviews was collected and utilized. It was difficult to obtain information about content and inventory during the field inventory process, thus significant data gaps of 'real world' data existed. In order to fill those data gaps, existing data from previous studies, Corps of Engineers Economic Guidance Memorandums (Gem's), and the CEFIT model was used.

A. Residential Content Values:

1) SAM Economic Team uses the Corps of Engineers Flood Inventory Tool (CEFIT) Residential Estimator by Marshall & Swift (in close cooperation with the Institute for Water Resources) to develop an appropriate structure-to-content ratio based on the various categories mentioned for depreciated replacement costs. Since limited data was available for the damage to contents from Katrina and other surge events, the methodology outline in the Corps of Engineer's Civil Works – Planning Guidance, Economic Guidance Memorandum 01-03 dated 12/2004 was adopted for the estimation of residential content values. Table 4-7 shows the content-to-structure ratio by occupancy type for residentially occupied dwellings.

Table 4-7.
Depreciated Replacement Factors by Occupancy Type

Category Name	Type	Construction Type	Content-to-Structure Ratio (%)
Residential[1]	Single Family Residence	Wood on Slab	100%
Residential[1]	Single Family Residence	Masonry on Slab	100%
Residential[1]	Single Family Residence	Wood on Piles	100%
Residential[1]	Single Family Residence	Masonry on Piles	100%
Commercial[2]	Duplex	N/A	23%
Commercial[2]	Triplex	N/A	23%
Commercial[2]	Town Homes	N/A	23%
Commercial[2]	Apartments	N/A	23%

1 Defined by Corps of Engineers EGM 01-03.
2 Multi-family residences (Duplexes, Triplexes, and Town homes) are given the commercial category name for depth damage purposes only, since they damage in a different way from single family residences even though they are still residential for discussion purposes.

B. Commercial/Industrial Inventory and Equipment Values:

1) SAM Economic Team interviewed businesses for inventory and equipment values based on categories of business types (fast food, grocery, restaurant, gas station, motel/hotel, etc.)

2) Where data gaps arose the team used previous studies, the FEMA Hazus MH program, and the Corps of Engineers Flood Inventory Tool (CEFIT) Residential Estimator by Marshall & Swift. The Commercial Contents Inventory Estimator was used to generate theses estimates. The team calculated estimates for a small, medium, and large business in each business category. Business such as large discount retailers e.g. Wal-Mart or home improvement stores like Home Depot had only one estimate each.

Each output generated consists of 4 inputs:

- The Standard Industrial Classification Code (sic code)
- Annual Revenue
- Square Footage
- Number of Employees

The inputs were altered to give realistic estimates for small, medium, and large businesses. The most important determinants in calculating an accurate output were the annual revenue and number of employees in a sample business.

3) The data was used to identify a typical inventory and equipment value by business type that will be applied to that category. Table 4-8 shows the commercial inventory and equipment values by category named and occupancy type.

Table 4-8.
Depreciated Replacement Factors by Occupancy Type

Category Name	Business Type	Annual Revenue ($)	Business Size	Total Estimated Employees	Depreciated Content Value ($)
Commercial	AIRLINE HANGER	$400,000	SMALL	7	**$44,404**
Commercial	AIRLINE HANGER	$1,500,000	MEDIUM	21	**$297,423**
Commercial	AIRLINE HANGER	$4,000,000	LARGE	35	**$722,361**

Commercial	STRIP MALL[2]	$16,135,840	MEDIUM	347	**$3,112,779**

1 Denotes real world identified values.
2 Strip Mall includes the rows from women's apparel through drug store.
3 All other values were derived from the Corps of Engineers Flood Inventory Tool (CEFIT) Residential Estimator Program.

C. Municipal/Churches:

1) Existing data from other Corps studies or the FEMA Hazus MH Program was used for municipal and church structures along with the Corps of Engineers Flood Inventory Tool (CEFIT) Residential Estimator by Marshall & Swift. The Commercial Contents Inventory Estimator was used to generate these estimates. Estimates were calculated for small, medium, and large churches and schools.

Each output generated consisted of 4 inputs:

- The Standard Industrial Classification Code (sic code)
- Annual Revenue
- Square Footage
- Number of Employees

The inputs were altered to give realistic estimates for small, medium, and large government buildings, schools, and churches. The most important determinants in calculating an accurate output were the annual revenue and number of employees in a sample school or church. The amount of annual funding was used as a substitute for annual revenue for schools. Both schools and churches have specific sic codes. Table 4-9 shows the content values for the different types of municipal structures.

Table 4-9.
Depreciated Replacement Factors by Occupancy Type

Category Name	Business Type	Annual Revenue ($)	Business Size	Total Estimated Employees	Depreciated Content Value ($)
Municipal	Church (Small)	$209,010	SMALL	6	**$7,360**
Municipal	Church (Medium)	$639,072	MEDIUM	21	**$97,539**
Municipal	Church (Large)	$7,500,000	LARGE	160	**$2,139,728**
Municipal	Government and School (Small)	$300,000	SMALL	15	**$47,132**
Municipal	Government and School (Medium)	$1,500,000	MEDIUM	35	**$216,118**
Municipal	Government and School (Large)	$5,000,000	LARGE	155	**$866,136**

Uncertainty pertaining to content value was estimated and put into the HEC-FDA and Beach-FX models as part of the process to calculate equivalent annual damages. Previous MOBILE DISTRICT feasibility studies estimated uncertainty of structure values between 5 and 15-percent. Since the nature of the sampling used for the MsCIP study was less rigorous than normal feasibility level efforts, a 25-percent uncertainty was used for content values.

CHAPTER V. INVENTORY AND FORECASTING CONDITIONS

This chapter describes the pre-Hurricane Katrina (historic) conditions, post-Hurricane Katrina (existing) conditions and the future without-project conditions for the fifty-four planning sub-units that define the surge inundation footprint up to the 40-foot NAVD88 contour (see figure 1.4.3. above).

5.1 Historic Conditions

5.1.1 Impacts of Hurricane Camille

The Mississippi Gulf Coast is no stranger to large storm surge events. On August 17, 1969, Hurricane Camille impacted the area in a similar fashion to Hurricane Katrina. Hurricane Camille made landfall at Bay St. Louis, Mississippi only miles way from Hurricane Katrina's landfall path. The total surge area ranged from lower Plaquemines Parish in Louisiana to Perdido Pass, Alabama. Maximum surge from Hurricane Camille on the Mississippi coast ranged from 21.7-feet above m.s.l. in planning unit one, to 24.2-feet above m.s.l. in planning unit two, and 15.8-feet above m.s.l. in planning unit 3.

Damage to the Mississippi Coast from Hurricane Camille was extensive. Federal relief expenditures topped 100 million dollars at 1970 prices, over 600 million dollars when accounted for inflation. The magnitude of this number is astounding considering that many of the relief programs that exist today did not exist for Hurricane Camille. Table 5-1 shows selected Hurricane Camille damage statistics. Tables 5-2 and 5-3 show damage to residential and commercial structures caused by Hurricane Camille surge.

Table 5-1.
Select Hurricane Camille Statistics.

Camille Statistics	Mississippi	Louisiana	Alabama
Persons Dead	135	9	Unknown
Persons Missing	27	0	Unknown
Families Suffering Loss	63,665	9,442	750
Dwellings Destroyed	3,881	1,771	10
Dwellings with major damage	12,112	1,753	50
Dwellings with minor damage	29,736	3,697	500
Trailers destroyed	406	664	12
Trailers with major damage	325	290	6
Farm buildings destroyed	645	114	5
Farm buildings with major damage	2,002	97	5
Small businesses destroyed or with major damage	569	110	14
Damage to public property	$200,000,000	$10,000,000	$500,000
Damage to private property	$750,000,000	$312,000,000	$7,500,000

Damage to Commercial Structures Caused by Hurricane Camille Surge.

County	Homes Destroyed	Homes Damaged	Total Homes Impacted
Hancock	52	150	**202**
Harrison	261	380	**641**
Jackson	4	57	**61**
Total	317	587	**904**

1 Source: Report on Hurricane Camille U.S. Army Corps of Engineers – MOBILE DISTRICT

Other damage statistics from Hurricane Camille include (1970 price levels):

- $23.5 million in industrial damages in Mississippi in flooded areas
- $7.8 million in damages to schools in Mississippi in flooded areas
- $3.5 million in damages to Mobile District navigation projects
- $10.1 million in damages to the two VA hospitals in Harrison County and $593,300 aggregate damage to other hospitals in Mississippi in flooded areas
- $5.2 million in damages to highways in Mississippi in flooded areas
- $2.1 million in damages to bridges in Mississippi
- $10.5 million in damages to vehicle in Mississippi in flooded areas
- $4.8 million in damages to Keesler Air Force Base
- Roughly $50 million in damages to Federal Government facilities
- $1.7 million in damages to Non-Federal Government facilities in Mississippi
- $14.7 million in marine damages in Mississippi
- $14.8 million cost of debris removal in flooded areas in Mississippi

5.1.2 Historic (Pre-Hurricane) Population Trends

The 1950-2000 population levels and growth for the U.S., Mississippi, the three-county study area, and each county are presented in Table 5-4. During this fifty year period, the population of the three-county study area grew by 186.6 percent. This is 5.6 times the Mississippi percentage population

growth of 33.2 percent and 2.2 times the U.S. percentage population growth of 86.0 percent for the same timeframe. The three-county area accounted for 32.7 percent of the nominal population growth for Mississippi from 1950 to 2000.

Table 5-4.
1950-2000 Population Levels and Growth (in thousands)

	United States	Mississippi	Three-County Study Area	Hancock County	Harrison County	Jackson County
1950	151,326	2,179	127	12	84	31
1960	179,323	2,178	189	14	119	56
1970	203,212	2,217	239	17	134	88
1980	226,546	2,521	301	25	158	118
1990	248,710	2,573	312	32	165	115
2000	281,421	2,903	364	43	190	131
50 Year Nominal Change	130,095	724	237	31	106	100
50 Year Percentage Change	86.0%	33.2%	186.6%	258.3%	126.2%	322.5%

5.1.3 Historic (Pre-Hurricane Katrina) Environmental Setting

The study area consists of the three coastal counties within the State of Mississippi: Hancock, Harrison, and Jackson counties; and the coastal (offshore) ecosystem including its barrier islands. This area ranges in elevation from sea level to about 30-feet NAVD88. The essentially flat to gently undulating, locally swampy Coastal Lowlands are underlain by alluvial, deltaic, estuarine, and coastal deposits and merge with the fluvial-deltaic plains of the streams of the area. According to the Cowardin et. al., *Classification of Wetlands and Deepwater Habitat of the United States*, there are five major wetland and deepwater systems, four of which are found within Coastal Mississippi. They include marine, estuarine, riverine, and palustrine wetland systems.

Within Coastal Mississippi, the marine system is the area along the Gulf of Mexico front south of the barrier islands. It is comprised of the intertidal beachfront of the barrier islands along the Gulf of Mexico, and subtidal which consists of the unconsolidated sandy water bottoms. The string of barrier islands are comprised of dynamic and diverse habitats and are part of a complex integrated system of beaches, dunes, marshes, bays, tidal flats, and inlets. These barrier islands are located along a littoral drift zone that moves sand westward creating three elongated islands and then to the westward most island (i.e. Cat) where littoral currents are not as well defined. From east to west, the islands are Petit Bois, Horn, Ship, and Cat. Ship Island was breached by prior hurricanes and now is actually two small islands, West Ship Island and East Ship Island, with a shallow sand bar between the two. Since Hurricane Camille in 1969, this breach has existed with varying amounts of natural rebuilding between later storms.

Under current conditions, the islands provide a natural boundary between the water's salinity [~33 parts per thousand (ppt)] of the open Gulf of Mexico and the brackish water found in Mississippi Sound. Salinity in the Sound during low flow periods range from 10 to 30 ppt. Highest salinities occur just south of Pascagoula and Gulfport and the lowest salinities in the Lake Borgne-Pearl River area. Mississippi Sound is a shallow coastal lagoon along northern Gulf of Mexico from Mobile Bay, Alabama, in the east to Lake Borgne, Louisiana, in the west. Circulation is driven by tides modified slightly with the wind. Gulf waters enter the Sound through the deep passes between the barrier islands with the help of tidal forces. This mixing of freshwater runoff and saline waters has created a dynamic estuarine environment. Mississippi Sound receives its major freshwater flow from the

Pascagoula and Pearl Rivers and is critical to the survival of numerous birds, mammals, fish, and other marine organisms of national importance.

Many different habitat types are found in and around the estuarine environment, including shallow open-waters, salt marshes, sandy beaches, mud and sand flats, oyster reefs, river deltas, tidal pools, and submerged aquatic vegetation (SAVs). These diverse ecosystems serve a variety of critical functions necessary to sustain a vital thriving commercial fishing industry of national economic significance. Prior to the hurricane season of 2005, sea grasses were restricted to the northern shores of the barrier islands and small patches throughout the immediate shorelines. These areas are characterized by *Diplanthera Wright* (Shoal grass)*, Cymodocea manatorum* (Manatee grass), *Thalassia testudinum* (Turtle grass), and *Ruppia maritime* (Widgeon grass). Approximately 20,000 acres of SAVs were present in Mississippi Sound prior to 1969; however, in late 1969, Hurricane Camille caused the destruction of the majority of these areas. In 1969, an estimated 13,000 acres of SAVs were documented and as of 1998, only 2,000 acres were documented (Moncrieff 1998).

Prior to the 2005 hurricane season, the majority of the shoreline in Coastal Mississippi consisted of manmade beaches beyond concrete seawalls. A few remaining areas along the shoreline consist of more natural areas, such as expanses of marsh along the western and eastern borders of the state. A natural beach and dune system, located along Belle Fontaine in the central portion of Coastal Mississippi, is the only natural beach remaining and has experienced severe erosion to a point that it is virtually non-existent. The beach of Coastal Mississippi provides a unique habitat for a variety of plants and animals. For example, 75% of migratory waterfowl live in or depend on coastal beaches during their lifespan. Dune vegetation provides nesting areas for several kinds of birds, such as least terns, and animals, such as mole crabs and rodents.

Wet Pine Savannah wetlands found in Coastal Mississippi provide for diverse habitat for a number of plants and animals including many threatened and endangered species found only in these unique habitats. Pine Savannah wetlands are commonly referred to as sponges that provide floodwater retention, groundwater recharge, and water purification. Development stresses were impinging upon these wetland habitats.

Coastal Mississippi supports an array of reptiles, amphibians, birds, and mammals. Reptiles and amphibians found in the area include snakes, turtles, lizards, toads, frogs, salamanders, and crocodilians. Coastal Alabama and Mississippi have a great diversity of reptiles including 23 species of turtles, 10 species of lizards, 39 species of snakes, and the alligator. Eighteen species of salamanders and 22 species of frogs and toads are indigenous to the coastal region.

Overall, the environmental conditions of Coastal Mississippi were already stressed prior to the hurricane season of 2005 and with its onset, many habitats were adversely impacted. However, these stressed conditions in Coastal Mississippi are irreversible with adequate planning and management.

5.2 Existing (Post-Hurricane Katrina) Conditions

5.2.1 Impacts from Hurricane Katrina

On August 29, 2005, Hurricane Katrina made land fall in Hancock County, Mississippi just east of the Pearl River. By virtually all accounts, it was the single largest disaster in U.S. history. Storm surge from Hurricane Katrina was the largest that has ever hit the continental United States. The surge inundated approximately 484 square miles of southern Mississippi. The relief expenditures in

Mississippi alone have totaled in the billions of dollars. Figure 5.2-1 shows the inundation footprint of Hurricane Katrina.

Figure 5.2-1. Hurricane Katrina Path and Extent of Hurricane Katrina Surge in Planning Units One, Two, and Three

5.2.2 Existing Structure Conditions

Data collected as part of the field inventory process was used to create a structure database. The structure database is the compilation of the data collection effort previously described. It includes each of the structure characteristics mentioned above, damage categories, structure occupancy types, first floor elevations, structure value, content value collected. These characteristics were put into the database along with the data collected from the tax assessor to create a structure database. This structure database represents the existing condition of the structures residing within the study area and the basis for the calculation of equivalent annual damages for the existing, future without-project and future with-project conditions using the HEC-FDA and Beach-FX programs. The structure database is intended to be a snap-shot in time of the structures within the study area. The use of this database was essential for the analysis conducted throughout the course of the MsCIP Comprehensive Plan.

The three planning units suffered tremendous devastation from Hurricane Katrina's surge. It is estimated that 32,446 structures were significantly destroyed (at least fifty-percent or more), with another 15,000 to 25,000 suffering moderate to minimal inundation damage. Of the structures sustaining significant destruction, 9,555 were in planning unit one, 16,528, in planning unit two, and 6,363 in planning unit three. Of those significant loss structures, approximately 19,000 claims were paid out by the Federal Emergency Management Agency's (FEMA's) National Flood Insurance Program (NFIP) totally over $2.3 Billion dollars, with the average claim around $137,000. Currently, no accurate data exists for uninsured losses, but estimates range in the billions of dollars. Table 5-5 displays the significantly damaged structures by planning unit and by structure category. Figures 5.2-2 through 5.2-14 show examples of the destruction caused by Hurricane Katrina in the three planning units.

Table 5-5.
Structures Damaged 50% or More by Planning Unit and by Category

	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Commercial	1,267	1,794	378	**3,439**
Residential	8,099	14,500	5,780	**28,379**
Municipal	127	89	136	**352**
Mobile Home	62	145	69	**276**
Total	**9,555**	**16,528**	**6,363**	**32,446**

5.2.3 Existing (Post-Hurricane Katrina) Socio-economic Conditions

This section contains a description of the existing conditions (post-Hurricane Katrina) demographic and economic characteristics of the study area. It also provides analysis of the interrelation of those characteristics. The people who live in the study area and the economic activities in which they are engaged are vital components of the study area. This information provides insight into the study area's socioeconomic characteristics and provides part of the basis for certain facets of the economic impact evaluation study.

5.2.3.1 Demographics (Population)

5.2.3.1.1 Recent Population Trends

The 2000-2005 population level and growth estimates for the U.S., Mississippi, the three-county study area, and each county are displayed in Table 5-6. The July 1, 2000 to July 1, 2005 timeframe is the most recent before Hurricane Katrina made landfall in late August of 2005. During this five year period, the population of the three-county study area grew by 2.86 percent. This is 1.4 times the Mississippi percentage population growth of 2.10 percent and 0.6 times the U.S. percentage population growth of 5.06 percent. The three-county study area accounted for 17.4 percent of the nominal population growth for Mississippi from 2000-2005.

Table 5-6.
2000-2005 Estimates of Population Levels and Growth

	United States	Mississippi	Three-County Study Area	Hancock County	Harrison County	Jackson County
July 1, 2000	282,216,952	2,848,634	364,863	43,283	189,699	131,881
July 1, 2001	285,226,284	2,856,108	366,362	43,944	189,512	132,906
July 1, 2002	288,125,973	2,863,091	367,498	44,607	189,996	132,895
July 1, 2003	290,796,023	2,874,171	367,790	45,166	189,189	133,435
July 1, 2004	293,638,158	2,892,668	372,885	45,821	192,129	134,935

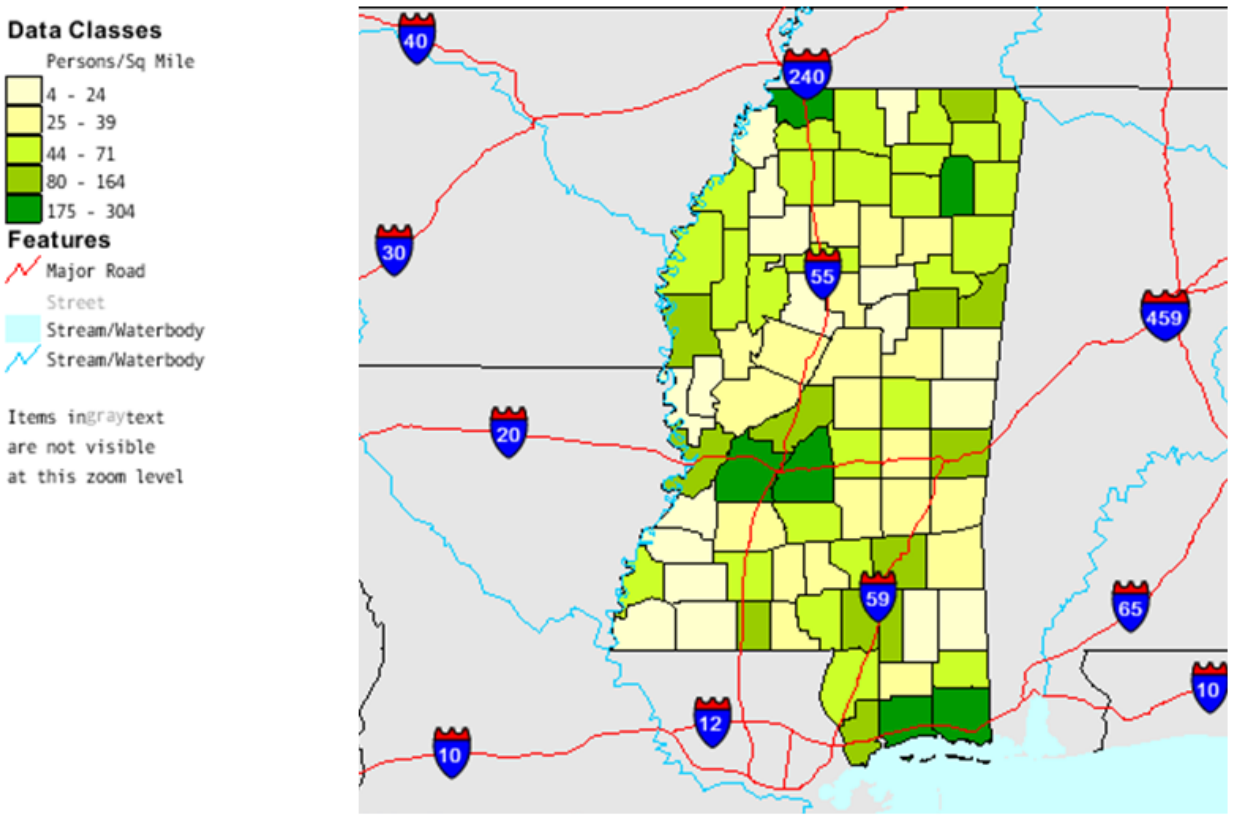
5 Year Nominal Change	14,290,109	59,862	10,441	3,263	3,488	3,690
5 Year Percentage Change	5.06%	2.10%	2.86%	7.54%	1.84%	2.80%

Source: U.S. Census Bureau, Population Division

5.2.3.1.2 Existing Condition (Post-Katrina) Population



The 2006 population level estimates for the U.S., Mississippi, the three-county study area, and each county are shown in Table 5-7. The table also displays each county's population and the study area's population as a percentage of the populations of the U.S. and Mississippi.

Table 5-7.
2006 Estimated Population Levels

	United States	Mississippi	Three-County Study Area	Hancock County	Harrison County	Jackson County
July 1, 2006 Population Estimate	299,398,484	2,910,540	342,873	40,421	171,875	130,577
Percentage of U.S. Population	100.0%	0.972%	0.115%	0.014%	0.057%	0.040%
Percentage of Mississippi Population		100.0%	11.8%	1.4%	5.9%	4.5%

Source: U.S. Census Bureau, Population Division

Figure 5.2-15 is a map displaying the population densities of counties in Mississippi. As can be seen from the map, the three-county study area is one of the more densely populated areas in Mississippi. It can also be seen that Hancock County has a lower population density than Harrison County or Jackson County.

Figure 5.2-15. 2006 Mississippi Population Density

5.2.3.1.3 Urban Growth and Distribution

The 2000-2004 population changes for the U.S., Mississippi, the three-county study area, each county, and major cities within each county are displayed in Table 5-8. The city with the greatest nominal or percentage population growth in the study area from 2000 to 2004 is Gautier with population growth of 5,172 persons or 44.28 percent.

Table 5-8.
2000-2004 Urban Growth and Distribution

	2000	2004	2000-2004 Nominal Change	2000-2004 Percentage Change
United States	281,421,906	293,655,404	12,233,498	4.35%
Mississippi	2,844,658	2,902,966	58,308	2.05%
Three-County Area	363,988	373,762	9,774	2.69%
Hancock County	42,967	45,933	2,966	6.90%
Bay Saint Louis	8,209	8,293	84	1.02%

5.2.3.2 Economy

5.2.3.2.1 Employment Distribution

The 2002 distribution of employment by major sectors for Mississippi, the three-county study area, and each county is shown in Table 5-10. Approximately 5.4% of Mississippi's Professional and Technical employment could be found in Hancock County in 2002. Hancock County is home to the John C. Stennis Space Center. The Stennis Space Center, with over 4,600 employees is NASA's primary center for rocket propulsion testing. Harrison County is a popular vacation destination for its beaches and casinos. Harrison County accounts for 26.9 percent of Mississippi's employment in the arts and 20.0 percent of Mississippi's employment in food and accommodation services. Jackson County features Pascagoula Harbor. In 2004, 66.7 percent of Mississippi's waterborne commerce volume and 1.3 percent of U.S. volume moved through Pascagoula Harbor. Pascagoula Harbor's annual volume increased 44% from 1986 to 2004. Northrop Grumman Ship Systems' Ingalls Operations, with over 10,000 employees, can also be found in Jackson County. Jackson County accounted for 8.8 percent of Mississippi's employment in manufacturing.

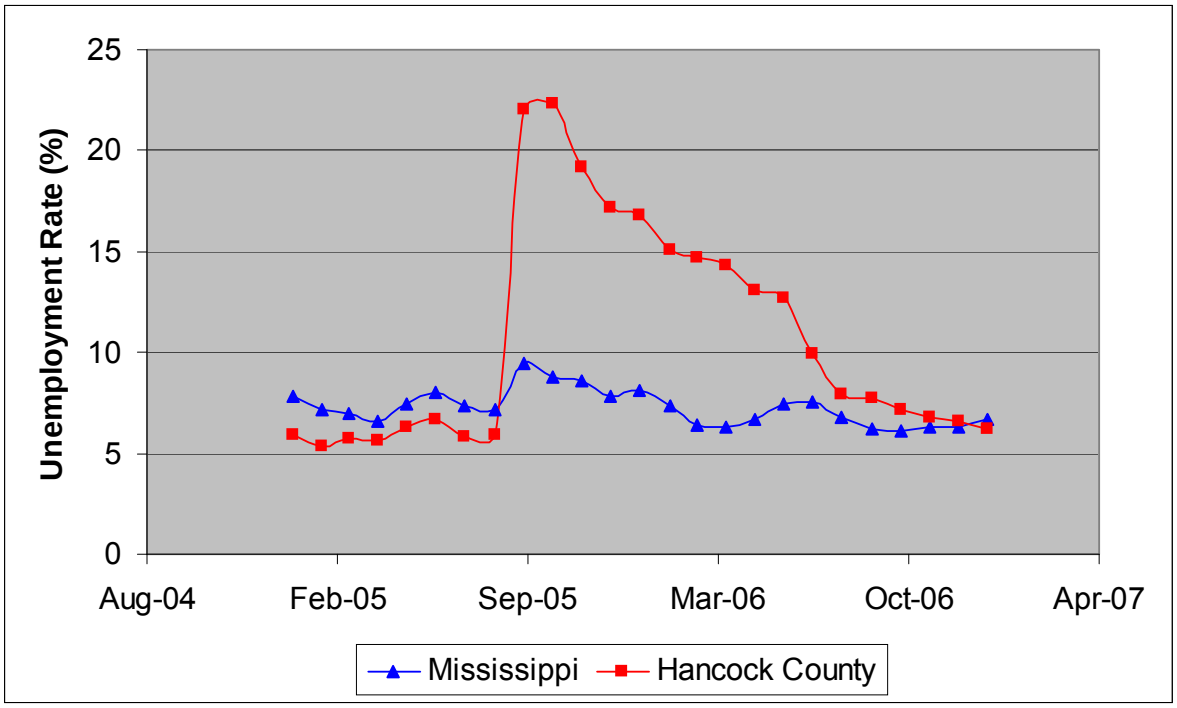

Table 5-10.
2002 Employment Distribution by Major Sector

	Mississippi	Three-County Study Area	Hancock County	Harrison County	Jackson County
Manufacturing	182,822	21,500	1,000	4,500	16,000
Wholesale	35,316	2,963	251	2,112	600
Retail	135,838	18,698	1,586	11,548	5,564
Real Estate	9,665	1,585	131	1,084	370
Professional & Technical	29,023	5,205	1,555	2,050	1,600
Administration	46,115	5,821	1,280	3,211	1,330

5.2.3.2.2 Unemployment

The non-seasonally adjusted unemployment rates for Mississippi and each county in the study area from January 2005 to January 2007 are displayed graphically in Figures 5.2-16, 5.2-17 and 5.2-18. These same numbers are also displayed in Table 5-11. Unemployment rates within the study area increased dramatically following Hurricane Katrina, but have since recovered to roughly pre-Katrina levels.

5.2.4 Existing (Post-Hurricane Katrina) Environmental Setting

Prior to the storms, Coastal Mississippi had already experienced large population growth over the last few decades. Loss and/or alteration of various habitats types (i.e. barrier islands, submerged aquatic vegetation (SAVs), marsh habitat – freshwater and estuarine, wet pine savannah, etc.) had adverse impacts on both fish and wildlife and also on those habitats upon which they depend. Erosion to the barrier islands could possibly increase salinity; thus, greatly changing ecological habitats that exist, which could lead to saltwater intrusion, increased wave action, and destroying coastal wetlands. Increased salinity within Mississippi Sound would impact shellfish and many other forms of marine life. At the Chandeleur Islands in Louisiana, loss of those island masses allows us to anticipate potential environmental changes. Initial assessments are showing SAVs diminishing, marsh erosion ongoing/accelerating, and wave energy having no natural barrier.

Following Hurricane Katrina, the Commerce Secretary declared a complete fisheries failure due to the extensive devastation to the processing facilities, docks, loss of boats, degradation of habitat, deposition of marine debris, and degraded water quality. Losses to many commercially important fisheries stock, foraging areas, nurseries, and etc. have been felt economically in the region. Increased salinity due to continued degradation of the barrier islands will result in detrimental impacts to the vital economic fisheries industry that the estuarine environment sustains.

Oyster reefs have been seriously impacted by Hurricane Katrina and all reefs in Coastal Mississippi were closed immediately following the storm, with some of them still remaining closed almost 2 years later. There are signs the reefs are beginning some of the healing processes on their own; however, much work will be needed to restore the oyster reefs to their former prime condition. Extensive sampling of the reefs is currently being conducted by the MDMR to provide information needed to plan extensive long-term recovery activities. Initial assessments of the reef conditions are underway but at present, are incomplete. Conditions of the reefs are highly variable. Generally, offshore areas were heavily scoured. Recent very heavy oyster spat set (less than one inch in length) was found in some of these areas with no spat set in other areas. Some light SAVs, marsh grass and drift wood were found. Inshore reefs generally had moderate to very low numbers of live oysters in some areas with other areas revealing no live oysters.

The coastal maritime forests on the barrier islands and also the mainland were almost entirely lost as a result of the storm. Almost 2 years following those events, approximately 90% of this habitat is still lost. Even prior to the storms, but especially after, wet pine savannah wetland habitat has been

under increased developmental pressures due to the extreme and urgent housing need faced by Mississippians as they are trying to rebuild. This habitat is becoming fragmented and with the increased development, fire maintenance is increasingly harder to perform. Due to the nature of the flat coastal plains with little relief, these lands are some of the first to be considered for housing development. These habitats are becoming fragmented causing a loss of wildlife corridors and contiguous expanses of habitat necessary for continued species existence. Coastal Mississippi has lost over half of its wet pine savannahs due to the urbanization throughout the area; thus, creating a threatened ecosystem that in turn is home to many threatened and endangered species. Because of the loss of these habitats, the species dependent upon them are increasingly becoming diminished. As a result of Hurricane Katrina and other storms of 2005, estuarine and freshwater marsh habitats were severely impacted by the debris that landed within its footprints; thus, clogging natural tidal and/or runoff flow. Furthermore, many historical marsh habitats (i.e. Shoreline Park) were noted to have detrimental damage due to its historical filling and development. Following those events, many historical habitats were identified that would benefit Coastal Mississippi upon its conversion back to its natural habitat. In conclusion, the hurricane season of 2005 greatly impacted the environmental setting of Coastal Mississippi.

5.3 Future Without-Project Conditions

5.3.1 Period of Analysis

For sensitivity purposes, the period of analysis used for the MsCIP Comprehensive Plan is a 100-year period, which was then converted to a 50-year period of analysis for those plan elements that would be recommended for construction. The base year used for the MsCIP Comprehensive Plan is the first year of the period of analysis. Typically, the base year is considered to be the first year that full project benefits come online and it is always the year to which benefits and costs of measures are discounted (present-worthed) back to in order to make an even ("apple-to-apples") comparison. The base year for the analysis used for the MsCIP Comprehensive Plan is the year 2012. Figure 5.3-1 depicts the methodology that was used for the 100-year period of analysis. This methodology was also used for the 50-year period of analysis, with the exception of the most likely future being 2061 (50 years), instead of 2111 (100 years).

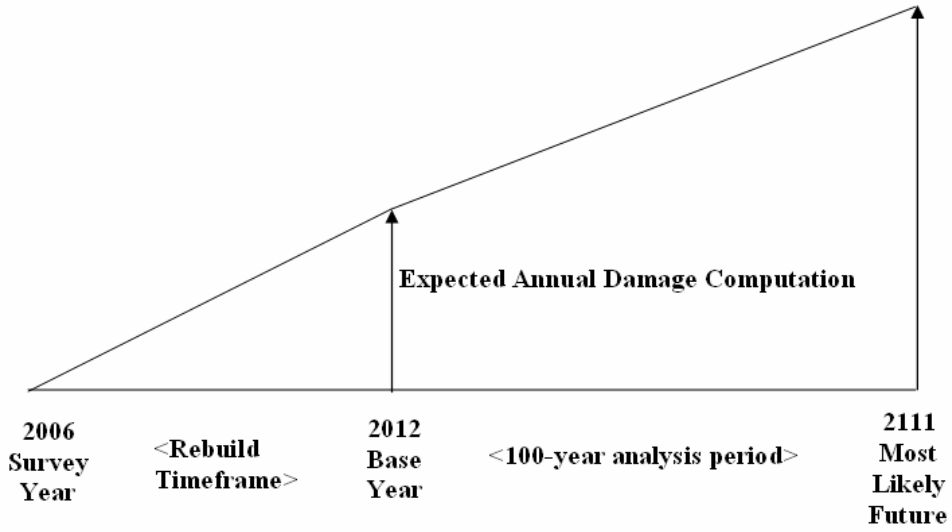

Figure 5.3-1. Period of Analysis used for Flood Damage Reduction and Hurricane and Storm Damage Prevention

5.3.2 Assumptions

The following assumptions were designed to construct the forecast estimate of the of the three county study area. The assumptions were based on discussions with state and local interests, various experts, and past experiences following devastating hurricanes along the northern Gulf Coast such as Hurricanes Camille and Fredrick. Further, these assumptions were based on an existing condition identified by using tax parcel data from the tax assessors of the three coastal counties and by conducting the field inventory to assess the extent of damages and where they occurred. These assumptions drive the future without-project structure inventory that was forecast and evaluated in HEC-FDA along with the hydrodynamic forecast conditions, which can be found in detail in the engineering appendix, to estimate future without-project inundation damages and damages reduced as result of potential measures.

- The base year for which costs and benefits are discounted is 2012.
- The discount rate used for this analysis is the FY-08 discount rate of 4-7/8-percent.
- The period of analysis for screening and sensitivity purposes is 100-years (2012 to 2111), however all measures recommended for construction will be converted back to a 50-year period of analysis (2012 to 2111). A more detailed discussion of this assumption can be found as a sensitivity analysis in chapter VII of this appendix.
- The demands for waterfront and near water living will not decrease in the future as a result of hurricanes (i.e. people will always want to live by the water).
- Only destruction of property occupied prior to Hurricane Katrina will be accounted for in forecasting (i.e. there will be no projection of previously undeveloped land).
- Destruction categories include significant (damaged 50-percent or more and must be completely rebuilt) and moderate to minimal (less than 50-percent rebuilt and can be either repaired or rehabilitated).
- Previously occupied structures that were destroyed as a result of Hurricane Katrina will be redeveloped and the population will return to at least pre-Katrina levels. Redevelopment is defined as the building back of structures that existed before Hurricane Katrina, not development that occurs on land that was undeveloped.
- Full redevelopment of previously occupied structures will occur by the base year 2012.
- Redevelopment of the study area could take the form of residential redevelopment (exactly the way it was pre-Hurricane Katrina) or a mixture of commercial/condominium and residential redevelopment. In addition to redevelopment, it is assumed that relative sea level rise could take the form of base, moderate or high relative sea level rise. The six future scenarios are outlined in the following section.
- Economic cycles such as recessionary and expansionary periods could, and probably will, have an impact on the timing and magnitude of the redevelopment of the coast over the period of analysis, but are not able to be predicted and are not accounted for in the forecast.
- An increase in relative sea level rise will probably occur over the period of analysis.
- Relative sea level rise is not a linear function, meaning that some years may experience more or less than other years. Since the amount of relative sea level rise in any given year is impossible to predict, a linear relationship is used to model relative sea level rise for purposes of forecasting.

- Given the majority of the coast is fronted by man-made seawalls and roadways and the majority of structures are immediately located by the water like other Gulf Coast and Eastern Seaboard communities, effects of future erosion on human development behavior will be none to minimal.

- Effects of future inundation caused by relative sea level rise could have any where from a minimal to a moderate effect on human development behavior, but those effects are currently difficult or impossible to measure and are not account for in this forecasting effort.

- Communities will adopt and adhere to FEMA guidelines under the National Flood Insurance Program (NFIP).

- FEMA guidelines require minimum heights that the first floor elevation must be built to in order to be included in the National Flood Insurance Program (NFIP). For the purposes of the redevelopment projected in this report, houses that will be rebuilt before the start of 2009 are assumed to be rebuilt to the Pre-Hurricane Katrina Base Flood Elevation (BFE) and those that are rebuilt between 2009 and 2011 will be rebuilt to the Advisory Base Flood Elevation (ABFE) as existed May 2007. The BFE and ABFE estimates vary in range of elevation depending on the planning sub-unit in question. Table 5-13 shows these heights by reach.

- Redevelopment is estimated to occur as follows:

Table 5-13.
Assumptions of Structure Redevelopment by Year

Year	Percent Redeveloped	Elevation of Redevelopment
2005	N/A	Hurricane Katrina Landfall (August 29th)
2006	10%	Pre-Hurricane Katrina Base Flood Elevations
2007	25%	Pre-Hurricane Katrina Base Flood Elevations
2008	40%	Pre-Hurricane Katrina Base Flood Elevations
2009	60%	Advisory Base Flood Elevations
2010	80%	Advisory Base Flood Elevations
2011	100%	Advisory Base Flood Elevations
2012	Full Redevelopment	Base Year

- Depth damage characteristics of structures (the percent of structure damage at various levels of inundation) are assumed and used to define economic damage as a result of inundation.

- The depth damage characteristics of structures vary by construction type and are similar to those in other parts for the Gulf Coast, particularly the New Orleans area. It is also assumed that the duration of surge inundation is approximately 24 hours, which is considered short-term duration. The depth-damage relationships are explained in more detail in Addendums A and B.

- Depreciated replacement cost of structures was used unless a structure was destroyed fifty-percent or more due to surge from Hurricane Katrina. For those structures damaged fifty-percent or more and must be rebuilt, full depreciated replacement cost was used to denote the value in the structure inventory.

5.3.3 Scenario Testing

5.3.3.1 Methodology

Forecasting future scenarios is an important part of the Corps planning process. In order to evaluate the true economic value of potential measures over the project life, a forecast is created based on the historic and existing information, as well as quantitative and qualitative assumptions about what may happen within the study area in the future. One method is to identify the 'most likely' future, or the best guess about what may happen based on observed variables and assumptions of both natural and human behaviors. Another method is to conduct scenario planning, where multiple future scenarios are created in order to evaluate what would happen if observed variables or assumptions do not happen as projected. The purpose of scenario planning is to attempt to answer 'what if' questions that arise when making forecasting assumptions and predictions.

For the Mississippi Coastal Improvements Project, the former method was chosen due to the size, scope, and complexity of the overall analysis. The six future without-project scenarios are displayed in table 5-14 summarizes the six future scenarios.

These six future without-project scenarios were based on existing condition characteristics, patterns of rebuilding following historical hurricanes within the specific area such as Hurricane Camille, patterns of rebuilding in other similar parts of the northern Gulf Coastal area such as Gulf Shores and Orange Beach, AL following Hurricane Fredrick, and potential impacts of relative sea level rise over the period of analysis. Following Hurricane Camille, the Mississippi Gulf Coast not only rebuilt the structures and infrastructure it lost to the devastating storm surge, but saw substantial growth in both residential and commercial infrastructure. However, it did not see a major shift in their proportion, i.e., the ratio of residential and commercial infrastructure did not immediately change as a result of a shift in behavior immediately following the storm. In contrast, the effects of Hurricane Fredrick to the Alabama Gulf Coast Communities of Gulf Shores and Orange Beach saw a fundamental shift of infrastructure from typically residential, to condominium and business structures. These two scenarios form the two rebuilding components of the future without-project scenarios; residential (a rebuild of the coastal area based on what existed prior to Hurricane Katrina) and residential and commercial (a rebuild of what type existed prior to Hurricane Katrina with a shift from residential to commercial along the coast.

The other component of the future without-project scenarios is relative sea level rise, or an estimate of the affect of eustatic sea level rise combined with subsidence. In order to evaluate the effects of this component, a range of relative sea level rise was identified and modeled and the details can be found in the engineering appendix. Three potential relative sea level rise settings were identified; base (historical relative sea level rise with no future projection), moderate (historical relative sea level rise and a future projection of up to 2.4-feet depending on location), and high (historical relative sea level rise and a future projection of up to 3.4-feet depending on location). These three components, coupled with the two redevelopment components, form the six future without-project scenarios used in the evaluation of this study.

As with any attempt to project the future, accuracy is limited by a host of factors such as timing (what if a recession hits), reality not fully matching the assumptions used (what if the redevelopment effort doesn't happen as fast as predicted or what if human behavior shifts in a way that was unforeseen), and on. In other words, any attempt to project the future will include some risk and uncertainty and therefore the intent of making these forecasts is to provide an estimate of what the future could be in order to evaluate the impacts of potential actions, not to say this is exactly what is going to happen.

Table 5-14.
Overview of Future Scenarios

Future Scenario	Redevelopment Type	Relative Sea Level Rise	Description
Future Scenario 1	Residential	Historical Only	Rebuild structures as existed pre-Hurricane Katrina with no relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 2	Mixed Residential & Commercial	Historical Only	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, no relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 3	Residential	Expected (up to 2.4-Feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina with up to 2.4-feet relative sea level rise over the This future scenario applies to all three planning units.
Future Scenario 4	Mixed Residential & Commercial	Expected (up to 2.4-Feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, a up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 5	Residential	High Rate (up to 3.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina with up to 3.4-feet of relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 6	Mixed Residential & Commercial	High Rate (Up to 3.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, up to3.4-feet of relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.

Future Scenarios One and Two are included only to evaluate the effects of relative sea level rise. These Future scenarios will not be used in the evaluation of potential measures. Futures Three, Four, Five, and Six will be the future scenarios by which potential measures will be evaluated depending on the planning unit.

5.3.3.2 Future Scenario 1

Scenario one is the full redevelopment of structures within the study area by the year 2012. Under this scenario, structures will be rebuilt as they were pre-Katrina. For example, if the structure was a residential structure pre-Katrina it will be rebuilt as a residential structure; commercial back to commercial; etc. It includes 220,776 tax parcels as defined by Hancock (planning unit one), Harrison (planning unit two), and Jackson (planning unit three) Counties, Mississippi. Of those parcels, 138,170 are structures including 22,313 are in planning unit one, 57,587 in planning unit two, and 58,270 in planning unit three. In addition to the redevelopment of structures, this scenario accounts for no relative sea level rise over the 100-year period of analysis (2012–2111). Table 5-15 displays the parcels by planning unit, category of structure, and by one-foot elevation contour. Table 5-16 displays the parcels for all three planning units by structure category and by one-foot elevation contour. Table 5-17 displays the value of structures and their contents by category and planning unit. **Note:** This scenario will not be used to evaluate potential measures in Chapter IV of this appendix because it does not adequately account for the effect of relative sea level rise. However, it will be used as a sensitivity analysis to evaluate the effects of the increment between a no relative sea level rise scenario and the expected relative sea level rise scenario.

Table 5-15.
Futures Without-Project Scenarios One, Three, and Five Inventory Parcels by Planning Unit and by Structure Category

Structure Categories	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Residential	17,907	49,121	49,688	**116,716**
Mobile Homes	498	2,497	3,553	**6,548**
Commercial	3,255	5,618	4,266	**13,139**
Municipal	653	351	763	**1,767**
Vacant Land	22,843	29,984	29,779	**82,606**
Total	**45,156**	**87,571**	**88,049**	**220,776**

5.3.3.3 Future Scenario 2

Scenario two is the full redevelopment of structures within the study area by the year 2012. Under this scenario, structures away from the water front in Planning Units one and two and all of planning unit three will be rebuilt as they were pre-Katrina. For example, if the structure was a residential structure pre-Katrina it will be rebuilt as a residential structure; commercial structures will be rebuilt back to commercial structures; etc. In addition, structures in planning units one and two, structures

along the Mississippi Sound and Back Bay water fronts will be rebuilt as condominiums and casinos. It includes 220,776 tax parcels as defined by Hancock (planning unit one), Harrison (planning unit two), and Jackson (planning unit three) Counties, Mississippi. Of those parcels, 138,199 are structures including 22,314 are in planning unit one, 57,615 in planning unit two, and 58,270 in planning unit three. In addition to the redevelopment of structures, this scenario accounts for no relative sea level rise over the 100-year period of analysis (2012–2111). Table 5-18 displays the parcels by planning unit, category of structure, and by one-foot elevation contour. Table 5-19 displays the parcels for all three planning units by structure category and by one-foot elevation contour. Table 5-20 displays the value of structures and their contents by category and planning unit. **Note:** This scenario will not be used to evaluate potential measures in Chapter IV of this appendix because it does not adequately account for the effect of relative sea level rise. However, it will be used as a sensitivity analysis to evaluate the effects of the increment between a no relative sea level rise scenario and the expected relative sea level rise scenario.

5.3.3.4 Future Scenario 3

Scenario three is the full redevelopment of structures within the study area by the year 2012. Under this scenario, structures will be rebuilt as they were pre-Katrina. For example, if the structure was a residential structure pre-Katrina it will be rebuilt as a residential structure; commercial structures will be rebuilt back to commercial structures; etc. Scenario three is the same structure inventory as scenario one with the addition of a relative sea level rise of 2.4-feet over the 100-year period of analysis (2012–2111). The structure inventory, structure values, and content values for future scenario three are described in detail in above section 5.3.3.2. This scenario will be used to evaluate potential measures in Chapter IV of this appendix.

5.3.3.5 Future Scenario 4

Scenario four is the full redevelopment of structures within the study area by the year 2012. Under this scenario, structures away from the water front in Planning Units one and two and all of planning unit three will be rebuilt as they were pre-Katrina. For example, if the structure was a residential structure pre-Katrina it will be rebuilt as a residential structure; commercial back to commercial; etc. In planning units one and two, structures along the Mississippi Sound and Back Bay water fronts will be rebuilt as condominiums and casinos. Basically, Scenario three is the same structure inventory as scenario one with the addition of a relative sea level rise of up to 2.4-feet over the 100-year period of analysis (2012–2111). The structure inventory, structure values, and content values for future scenario three are described in detail in above section 5.3.3.3. This scenario will be used to evaluate potential measures in Chapter IV of this appendix.

5.3.3.6 Future Scenario 5

Scenario five is the same structure inventory as scenario one with the addition of a relative sea level rise of up to 3.4-feet depending over the 100-year period of analysis (2012–2111). The structure inventory, structure values, and content values for future scenario three are described in detail in above section 5.3.3.2. This scenario will be used to evaluate potential measures in Chapter IV of this appendix.

5.3.3.7 Future Scenario 6

Scenario six is the same structure inventory as scenario two with the addition of a relative sea level rise of up to 3.4-feet over the 100-year period of analysis (2012–2111). The structure inventory, structure values, and content values for future scenario three are described in detail in above section 5.3.3.3. This scenario will be used to evaluate potential measures in Chapter IV of this appendix.

5.3.4 Future Without-Project Surge Risk

5.3.4.1 Maximum Probable Intensity (MPI) Event

Computer simulations have predicted[2] how far inland storm surge will extend if the worse-case hurricane or maximum possible intensity (MPI) event hits the Mississippi coast. The extent of the surge from the MPI event is shown in Figure 5.3-2. The maximum water level of the MPI event along the Mississippi coastline was determined to be approximately 30 feet along the entire western half of the state and east of Pascagoula. The landward extent of the inundation indicates the storm surge reaches Interstate 10 for much of the western portion of the state. Lower peaks near Biloxi and Mobile Bay (24-27 feet) may be attributed to the protection afforded by the barrier islands. The line of defense accordingly approximates the 24 to 30 feet. (NAVD '88 datum) contours.

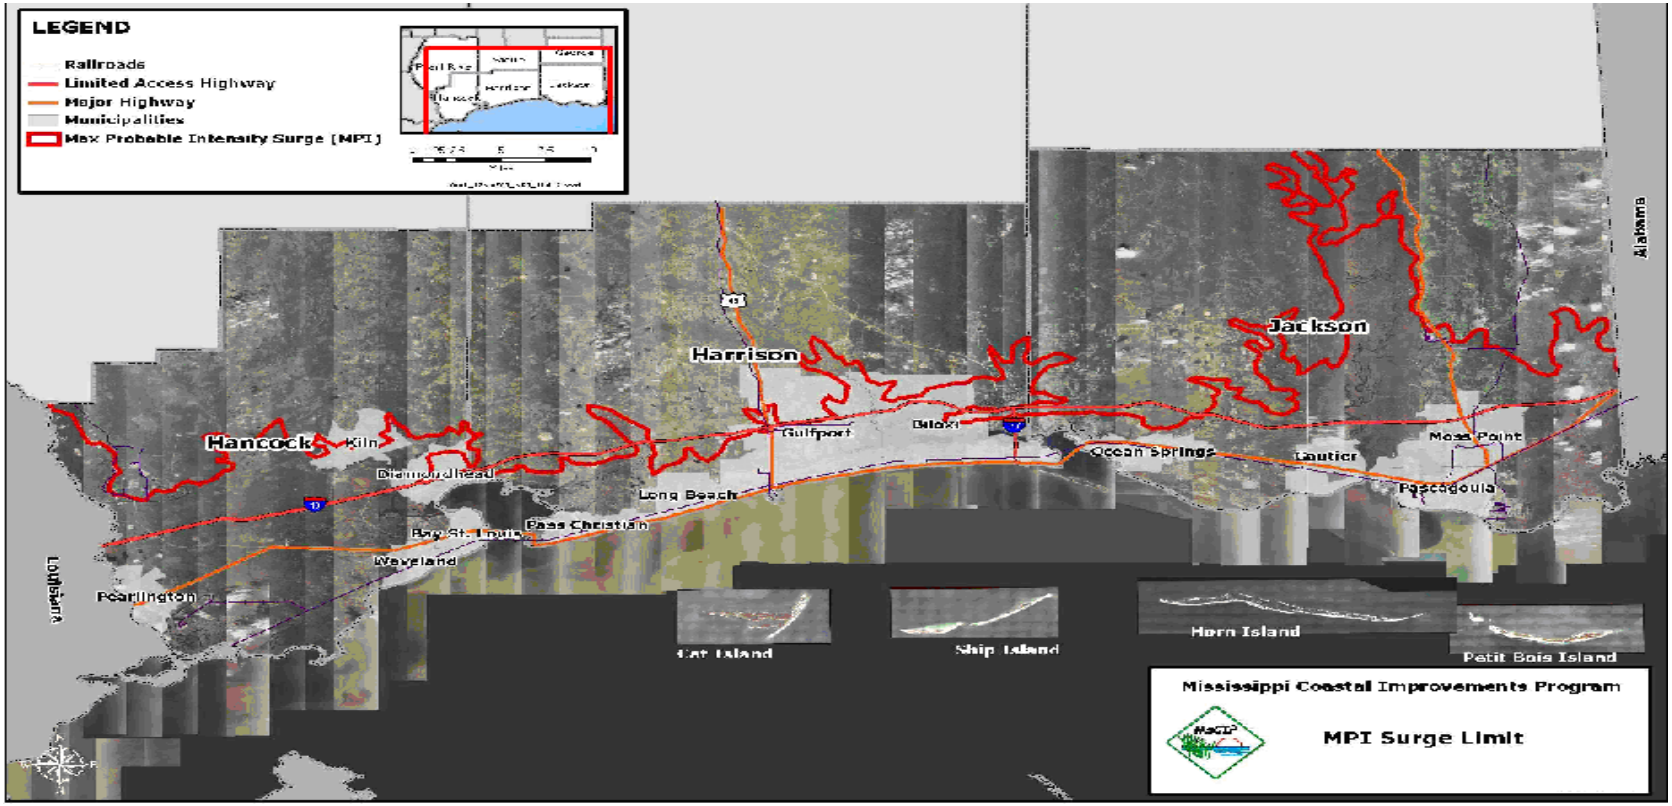

Figure 5.3-2. Maximum Probable Intensity Footprint for the Without Project Condition

[2] Storm surge modeling is described in the MsCIP Comprehensive Plan Engineering Appendix.

Figure 5.3-3 shows the population density of the three planning units within the MPI event footprint.

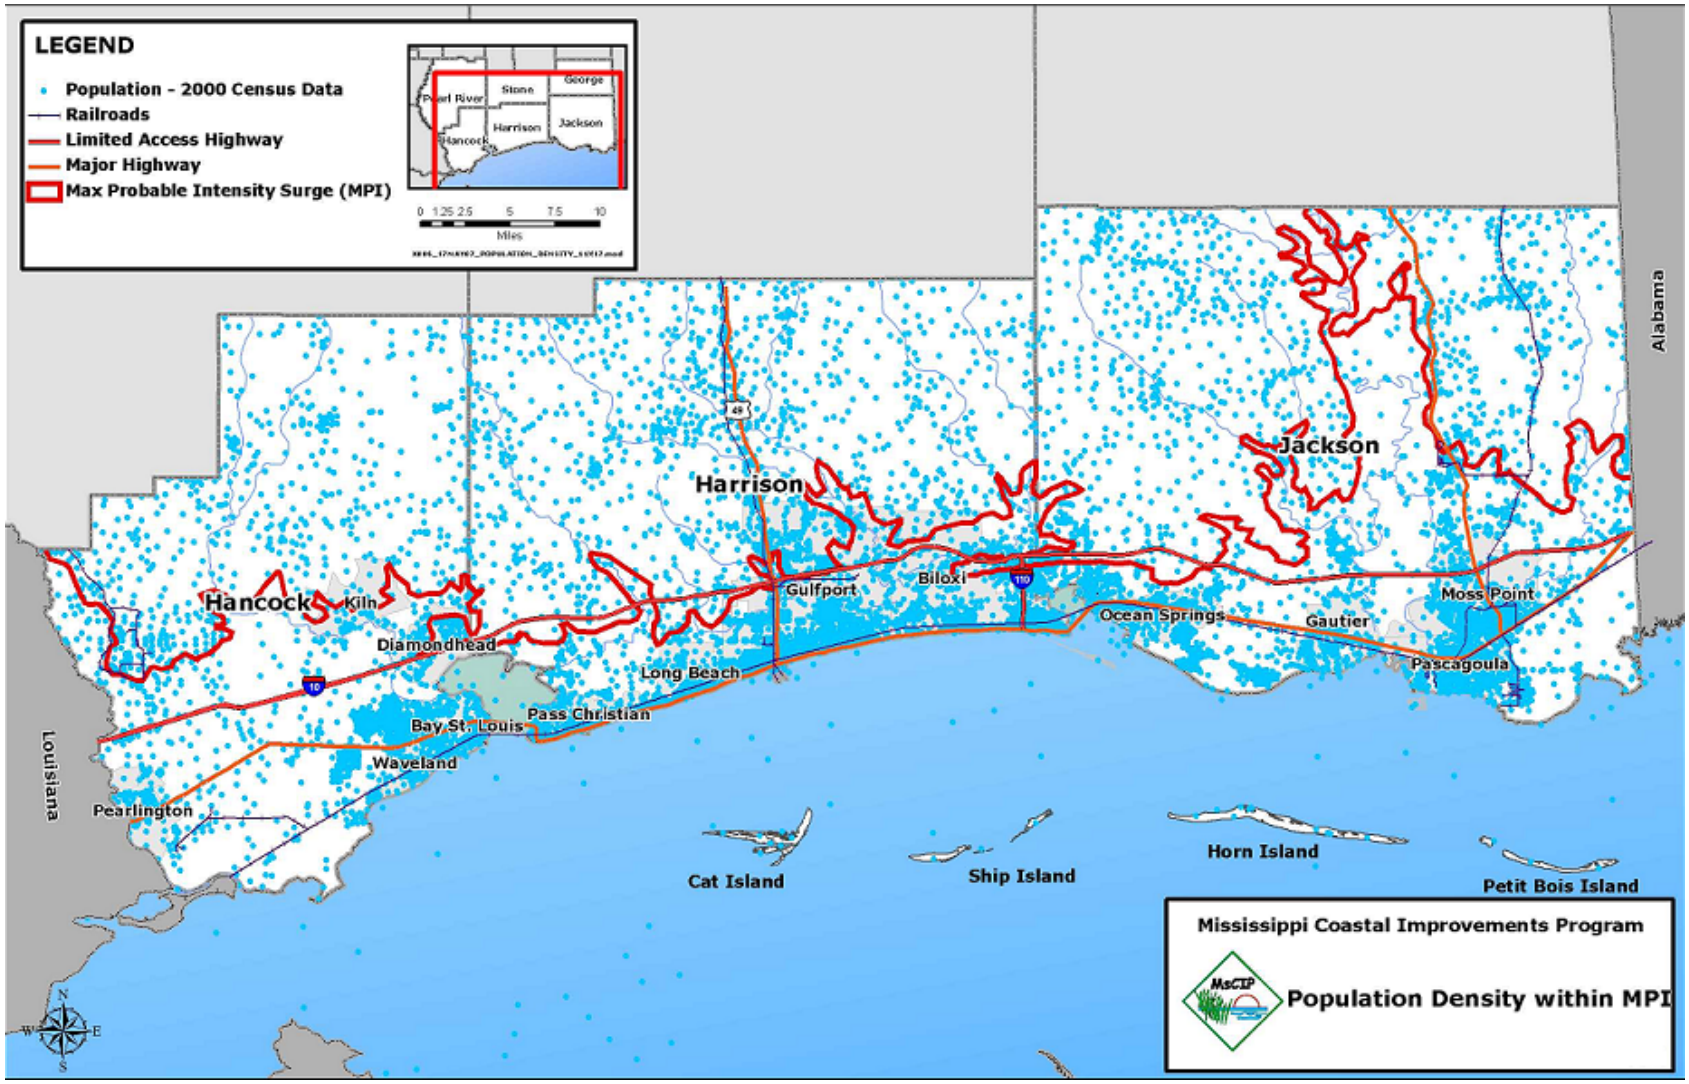

Figure 5.3-3. Population within the Future Without-Project Maximum Probable Intensity Surge Footprint

Figure 5.3-4 shows the various risk zones within the extent of the MPI event.

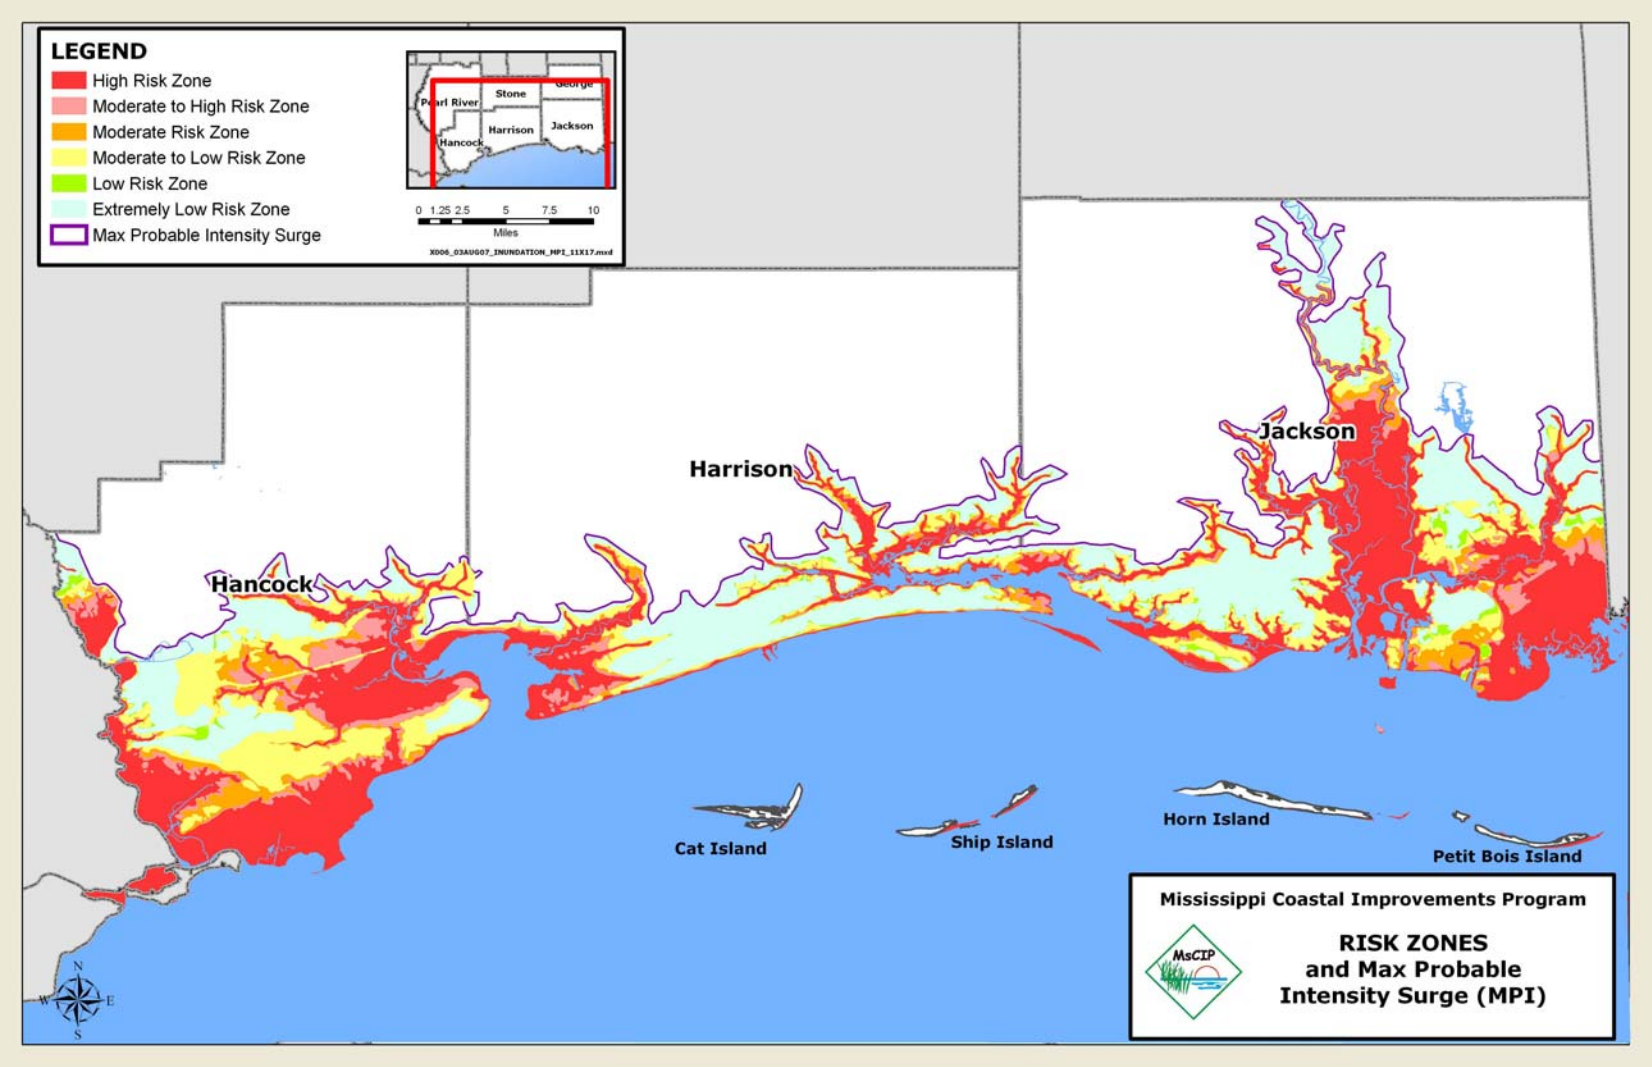

Figure 5.3-4. Risk Zones within the Maximum Probable Intensity Area

5.3.5 Summary of Future Without-Project Damages

This section describes the equivalent annual without-project damages for the entire study area to the 40-foot NAVD88 contour. Future without-project damages for the entire study area were calculated using the HEC-FDA program. Equivalent annual without-project damages were calculated for each of the 54 planning sub-units and each of the six future scenarios. The equivalent annual damages for specific areas, or planning sub-units, will be described in detail in the various sections of Chapter IV of this appendix. Note: The equivalent annual without-project damages calculated at the beach and dune sites will be evaluated on a localized scale using the Beach-FX program. Section 6.2 will describe in detail the equivalent annual without-project damages at the beach and dune sites. The remainder of this section will depict the outputs of the HEC-FDA modeling only.

The results of the without project conditions for all fifty-four planning sub-units in depicted in Table 5-21. The table shows the total equivalent annual without-project damages by planning unit for each of the future scenarios. These values represent the annual damages if no action is taken and if the study area is redeveloped to the levels described in Table 5-14. Figure 5.3-5 shows the without-project damages by future scenario. Table 5-22 shows the expected annual without-project damages by reach and by future scenario.

Table 5-21.
Equivalent Annual Without-Project Damages by Planning Unit and Future Scenario

Without-Project Damages	Future 1[2] Damages	Future 2[2] Damages	Future 3 Damages	Future 4 Damages	Future 5 Damages	Future 6 Damages
Planning Unit One	$198,960,000	$202,060,000	$218,050,000	$222,220,000	$237,310,000	$241,520,000
Planning Unit Two	$91,260,000	$94,680,000	$103,280,000	$107,120,000	$115,470,000	$119,760,000
Planning Unit Three	$88,670,000	$88,670,000	$104,700,000	$104,700,000	$122,420,000	$122,420,000
Total	**$378,890,000**	**$385,410,000**	**$426,030,000**	**$434,040,000**	**$475,200,000**	**$483,700,000**

Damages are rounded to the nearest ten thousand.
1 Futures Two, Four, and Six do not apply to planning unit three, therefore total damages are the same as future scenarios one, three, and five.
2 Future Scenarios one and two will be used to evaluate the impacts of relative sea level rise only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

1 Given the magnitude of the future-without project damages depicted in this table, a sensitivity analysis was conducted with regard to multiple criteria including period of analysis and first floor elevation uncertainty. The results of the sensitivity analysis can be found in Chapter VII of this appendix.
2 Future Scenarios one and two will be used to evaluate the impacts of relative sea level rise only, and will not be discussed in the

Equivalent Annual Without-Project Damages by Planning Sub-Unit and Future Scenario[1]
(continued)

Planning Unit and Sub-Unit	Future 12 Damages	Future 22 Damages	Future 3 Damages	Future 4 Damages	Future 5 Damages	Future 6 Damages

direct evaluation of potential measures detailed in Chapter IV of this appendix.

5.3.5.1 Future Without-Project Stage-Damage for Selected Reaches

As shown in the previous table, the magnitude of the equivalent annual damages is very large for the six future without-project scenario conditions. Planning sub-units two, five, six, eight, twelve, eighteen, nineteen, twenty-one, and fifty-two each have equivalent annual damages in the tens of millions of dollars. In order to communicate the effects that are being modeled, comparisons of the total present worth of damages by frequency event to the total economic value in the planning sub-units shows the nature of the damages that are being expressed by the HEC-FDA modeling.

This section is intended to dissect those nine planning sub-units for future without-project scenario one. This future scenario was chosen because it is the baseline case upon which the other Future Scenarios were built. It does not include the effects of a different type of redevelopment than what actually existed pre-Hurricane Katrina and it does not include the effects of relative sea level rise. Table 5-23 shows the total economic value input into HEC-FDA for each of these nine reaches.

Table 5-23.
Total Structure and Content Value for Selected Planning Sub-Units

Planning Sub-Unit	Structure Value Thousand $'s	Content Value Thousand $'s	Total Economic Value Thousand $'s
2	$1,359,527.34	$1,969,251.33	$3,328,778.67
5	$313,687.82	$256,492.02	$570,179.84
6	$168,756.85	$154,811.46	$323,568.31
8	$2,995,946.35	$987,316.91	$3,983,263.25
12	$1,174,270.25	$1,594,487.74	$2,768,757.99
18	$706,994.07	$365,494.03	$1,072,488.09
19	$95,273.76	$23,225.26	$118,499.03
21	$1,268,159.01	$761,125.18	$2,029,284.19
52	$909,227.20	$1,641,424.90	$2,550,652.10

Tables 5-24 through 5-32 display the total present worth of the stage damages for the 0.9990 to 0.0010 exceedance probability events. These damages are what the HEC-FDA model uses to calculate equivalent annual damages. Those stage damages are then compared to the total economic value for the reach to show what percentage of damage is expected. In each of the reaches, the 0.0100 to the 0.0010 probability events dominate the damage curve.

Probability and stage expressed in these tables was defined by the MOBILE DISTRICT Engineering Division working in concert with the Engineer Research and Development Center (ERDC). Stage mentioned in the tables is the mean stage for the event; however the HEC-FDA model incorporates uncertainty to two standard deviations, or approximately the 95% confidence level. For more detail about the exceedance probability functions, see the engineering appendix.

Table 5-24.
Stage Damage by Event for Future Scenario One, Planning Unit One, Planning Sub-Unit Two

1/ Exceedance probability functions go to two standard deviations over the mean stage in the HEC-FDA model.
2/ Explanation of the exceedance probability function can be found in the engineering appendix.

5.3.6 Impacts of Redevelopment Scenarios on Equivalent Annual Without-Project Damages

The two redevelopment scenarios, as previous discussed, are the redevelopment of the area back to the same way it was pre-Hurricane Katrina (residential redevelopment) and a redevelopment of the way the area was pre-Hurricane Katrina with commercial/condominium redevelopment (mixed redevelopment) along the water fronts of planning units one and two. The impacts of different redevelopment and the corresponding relationship to damages is a combination of different structure and content values that would could occupy the same space (five single family residences versus and condominium) and the depth-damage relationship of those different structures. The measurement of impacts from various redevelopment scenarios can be expressed by comparing the residential redevelopment to the mixed redevelopment for a given relative sea level rise scenario, or future scenario one versus future scenario two, future scenario three versus future scenario four, and future scenario five versus future scenario six. Tables 5-33 and figure 5.3-6 show the comparison of future scenario one to future scenario two, table 5-34 and figure 5.3-7 show the comparison of future scenario three to future scenario four, and table 5-35 and figure 5.3-8 compare future scenario five to future scenario six.

Table 5-33.
Comparison of Residential Redevelopment vs. Mixed Redevelopment for Expected Relative Sea Level Rise

Without-Project Damages	Future 1[1] Damages	Future 2[1] Damages	% Change from Future One
Planning Unit One	$198,960,000	$202,060,000	1.56%
Planning Unit Two	$91,260,000	$94,680,000	3.75%
Planning Unit Three	$88,670,000	$88,670,000	0.00%
Total	**$378,890,000**	**$385,410,000**	**1.72%**

Damages are rounded to the nearest ten thousand.
1 Future Scenarios one and two are used here to evaluate the impacts redevelopment only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

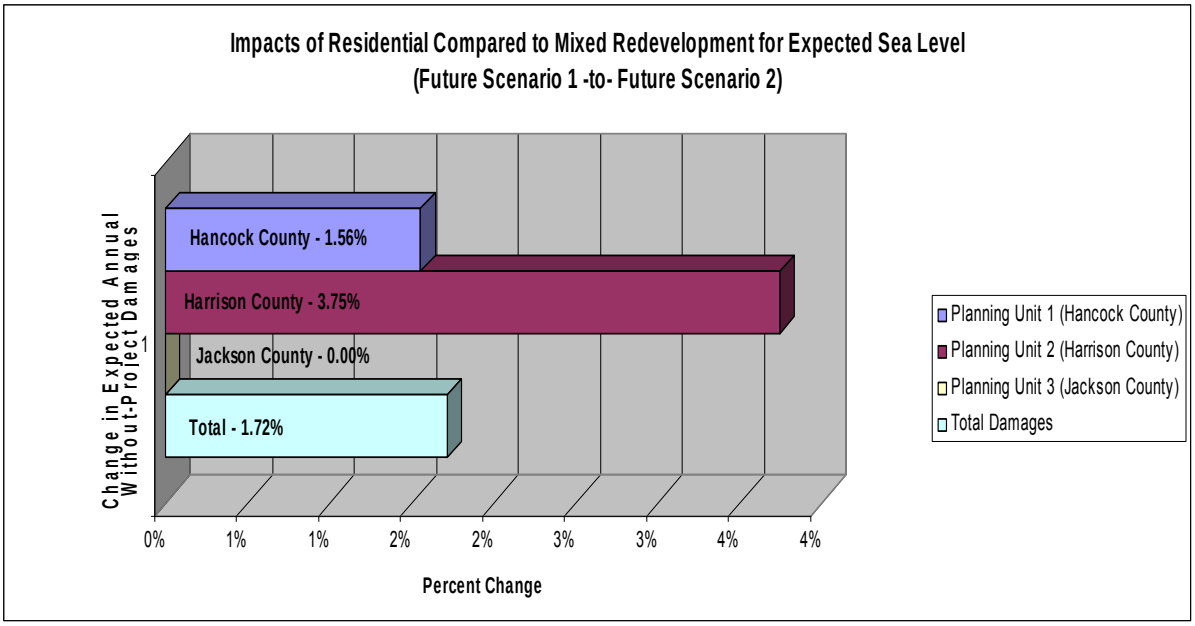

Figure 5.3-6. Impacts of Residential Compared to Mixed Redevelopment for Expected Relative Sea Level

Table 5-34.
Comparison of Residential Redevelopment vs. Mixed Redevelopment for Expected Relative Sea Level Rise

Without-Project Damages	Future 3 Damages	Future 4 Damages	% Change from Future One
Planning Unit One	$ 218,050,000	$ 222,220,000	1.91%
Planning Unit Two	$ 103,280,000	$ 107,120,000	3.72%
Planning Unit Three	$ 104,700,000	$ 104,700,000	0.00%
Total	**$ 426,030,000**	**$ 434,040,000**	**1.88%**

Damages are rounded to the nearest ten thousand.

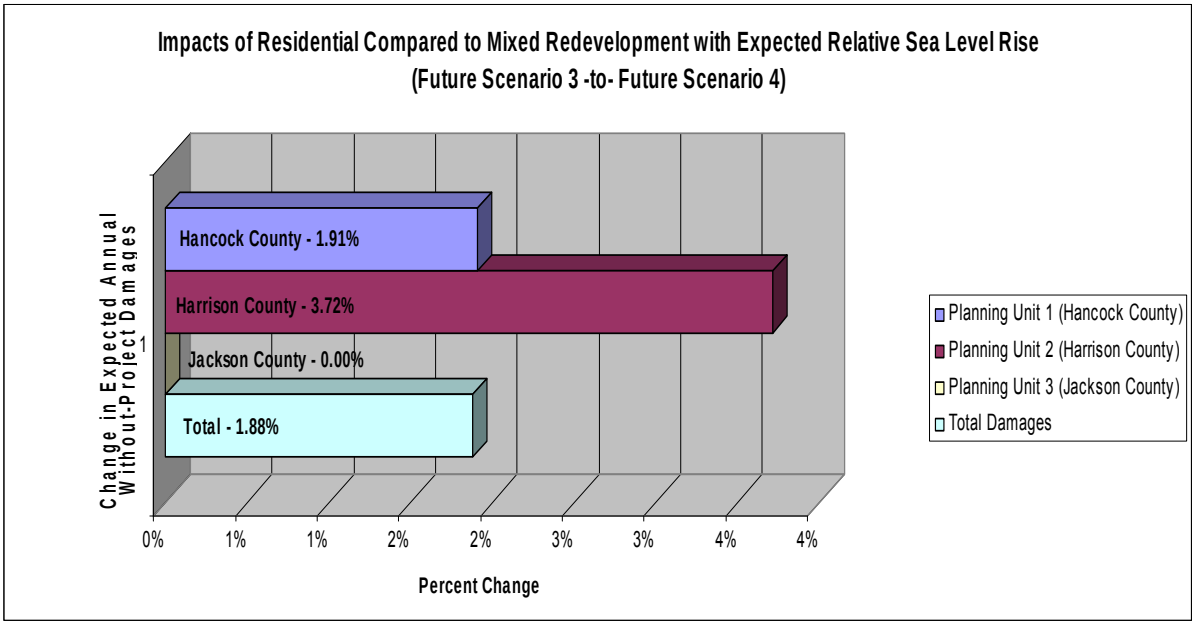

Figure 5.3-7. Impacts of Residential Compared to Mixed Redevelopment for Expected Relative Sea Level Rise

Table 5-35
Comparison of Residential Redevelopment vs. Mixed Redevelopment for Expected Relative Sea Level Rise

Without-Project Damages	Future 4 Damages	Future 6 Damages	% Change from Future One
Planning Unit One	$222,220,000	$241,520,000	1.77%
Planning Unit Two	$107,120,000	$119,760,000	3.72%
Planning Unit Three	$104,700,000	$122,420,000	0.00%
Total	**$434,040,000**	**$483,700,000**	**1.79%**

Damages are rounded to the nearest ten thousand.

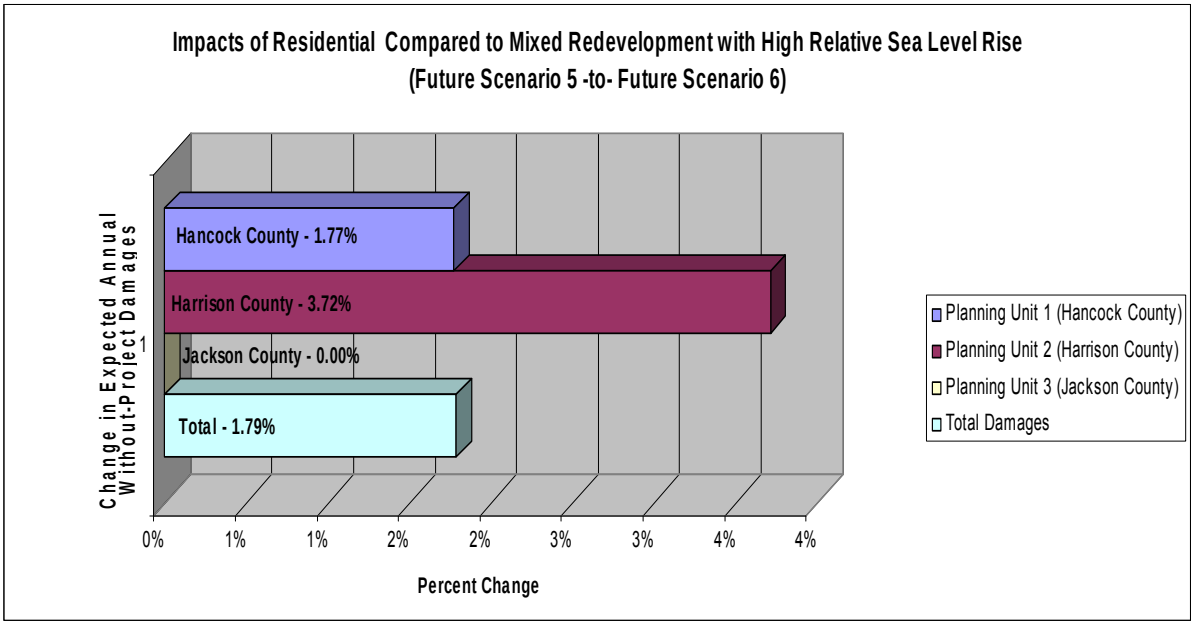

Figure 5.3-8. Impacts of Residential Compared to Commercial Redevelopment for High Relative Sea Level Rise

5.3.7 Impacts of Relative Sea Level Rise on Equivalent Annual Without-Project Damages

The impact of relative sea level rise over the period of analysis is the increase in damages when everything but relative sea level rise remains constant. This can be evaluated by comparing futures one, three and five against each other and futures two, four, and six against each other. The impact of relative sea level rise when compared to futures one, three, and five shows the effects that could be expected if the study area rebuilds exactly the way it was pre-Hurricane Katrina. The impact of relative sea level rise as compared to futures two, four, and six represent what could be expected given the rebuilding of the study area to a mixture of its pre-Hurricane Katrina setting with the shift from a residential coastline in planning units one and two to a commercial and condominium setting.

The increased equivalent annual damages are the direct effect of several phenomenon's' that result from the increased inundation. First, the higher water levels attributed to the expected relative sea level rise (Futures three and four - 2.0-feet) and high sea level rise (Futures five and six - 3.4-feet) would cause more damage to structures and their contents that would already be expected to be impacted under the existing relative sea level scenarios (Futures one and two). The second effect of increased relative sea level rise is that there would be damages to structures and their contents that would not be expected under the existing relative sea level rise scenarios, or completely new damage specifically attributable to the increased relative sea level rise. Table 5-36, figure 5.3-9, and figure 5.3-10 compares the effects of relative sea level rise on futures one, three, and five. Table 5-37, figure 5.3-11, and figure 5.3-12 compares its effects on futures two, four, and six.

Table 5-36.
Impacts of Relative Sea Level Rise on Futures One, Three, and Five

Without-Project Damages	Future 1[2] Damages	Future 3 Damages	% Change from Future One	Future 5 Damages	% Change from Future One
Planning Unit One	$198,960,000	$218,050,000	9.59%	$237,310,000	19.28%
Planning Unit Two	$91,260,000	$103,280,000	13.17%	$115,470,000	26.53%
Planning Unit Three	$88,670,000	$104,700,000	18.08%	$122,420,000	38.06%
Total	**$378,890,000**	**$426,030,000**	**12.44%**	**$475,200,000**	**25.42%**

Damages are rounded to the nearest ten thousand.
1 Future Scenario one is used here to evaluate the impacts of relative sea level rise only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

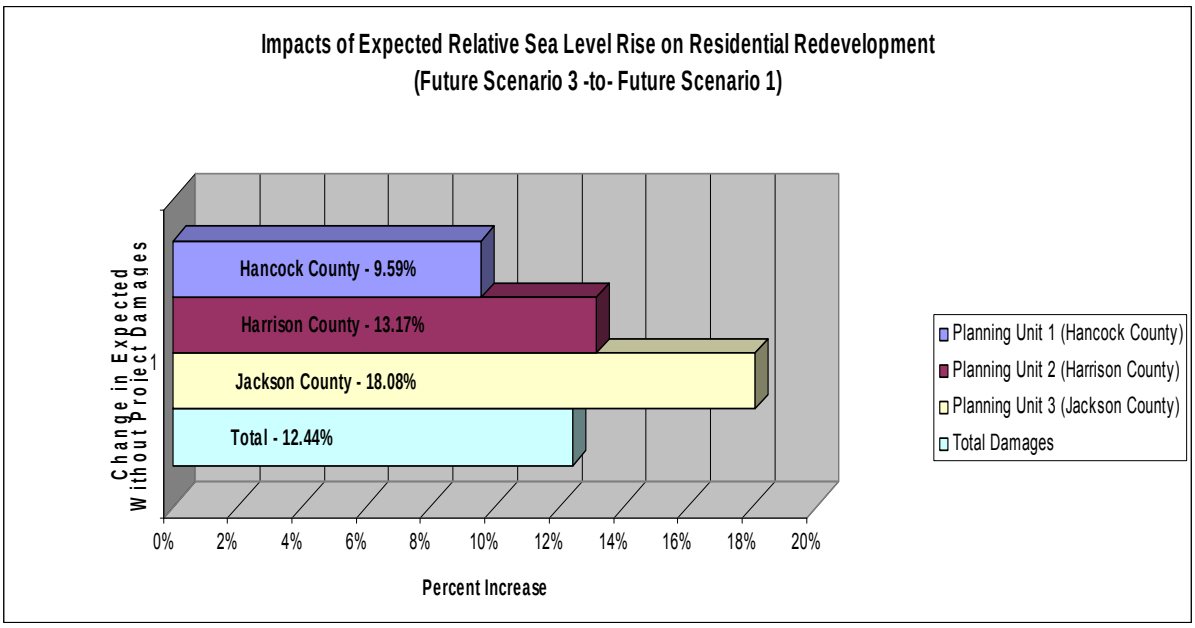

Figure 5.3-9. Impacts of 2.0-feet of relative sea level rise on a residential redevelopment

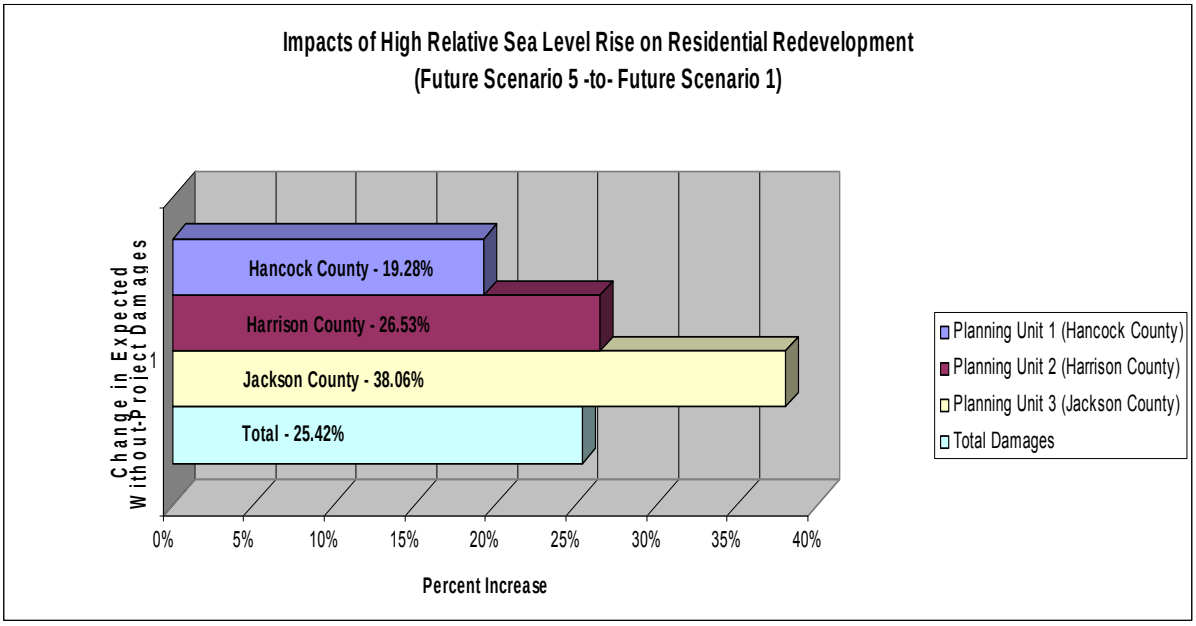

Figure 5.3-10. Impacts of 3.4-feet of relative sea level rise on a residential redevelopment

Table 5-37.
Equivalent Annual Without-Project Damages by Planning Unit and Future Scenario

Without-Project Damages	Future 2[2] Damages	Future 4 Damages	% Change from Future Two	Future 6 Damages	% Change from Future Two
Planning Unit One	$202,060,000	$222,220,000	9.98%	$ 241,520,000	19.53%
Planning Unit Two	$94,680,000	$107,120,000	13.14%	$ 119,760,000	26.49%
Planning Unit Three	$88,670,000	$104,700,000	18.08%	$ 122,420,000	38.06%
Total	**$385,410,000**	**$434,040,000**	**12.62%**	**$ 483,700,000**	**25.50%**

Damages are rounded to the nearest ten thousand.
1 Futures Two, Four, and Six do not apply to planning unit three, therefore total damages are the same as future scenarios one, three, and five for planning unit three.
2 Future Scenario two is used here to evaluate the impacts of relative sea level rise only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

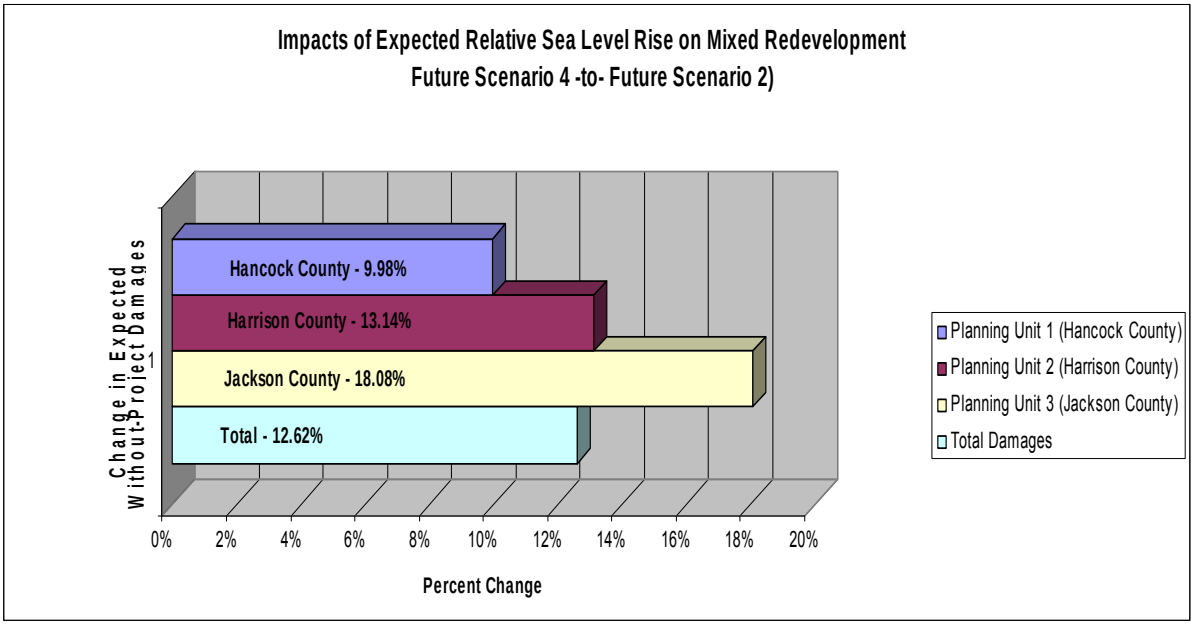

Figure 5.3-11. Impacts of 2.0-feet of relative sea level rise on a mixed redevelopment

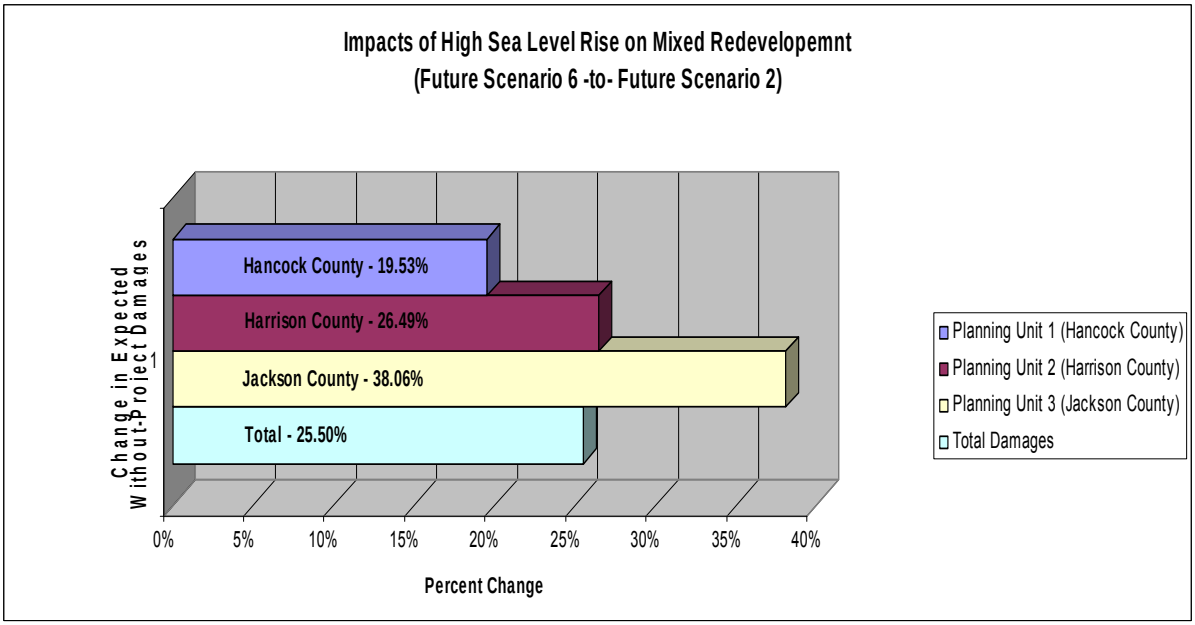

Figure 5.3-12. Impacts of 2.0-feet of relative sea level rise on a mixed redevelopment

CHAPTER VI. DEVELOPMENT AND EVALUATION OF MEASURES

This section describes steps three and four of the Corps six step planning process. These steps are the development of potential measures and the evaluation of those measures as compared to the without project conditions. Initial analysis yielded an extensive list of potential measures that were appropriate to a given site or problem area. The sites/problem areas are illustrated in the Main Report. The development of preliminary measures for structural and non-structural damage reduction is discussed in detail in the Engineering Appendix. The development of preliminary measures for ecosystem restoration and saltwater intrusion remediation is discussed in detail in the Environmental Appendix.

Many measures were initially evaluated and screened, based on technical or environmental criteria, and are not discussed here. Those measures that were found to be technically sound for a particular application, and environmentally sound, in regards to potential impacts to environmental resources, were forwarded for consideration, into the next phase of analysis. Measures forwarded into Round 2 of the evaluation and screening process were developed to a greater level of detail, to allow more detailed comparison, and potential modification for further study. The development of more detail included preliminary design and cost estimation, coastal, hydrologic and/or hydraulic analysis and design, environmental analysis, and determination of potential damages prevented, residual damages, and other factors. This latter process is discussed in more detail in the main report.

6.1 Overview of Benefits and Cost Evaluation

This section describes an overview of the methodology and steps taken in the calculation of benefits and costs. The principles for the overall process are the same no matter the area in question. Since the scope and scale of the comprehensive plan is so extensive, the methodologies utilized will be described here, and then summary tables and paragraphs will be used in the following sections that describe the evaluation of the various measures.

6.1.1 Calculation of National Economic Development Benefits

Except for the Beach and Dune placement measures described in detail in section 6.3, all of the surge inundation reduction benefits for the various measures were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) program. For the analyses in this comprehensive plan, National Economic Development (NED) benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

Equivalent annual flood damages for the various measures and alternatives at each area were evaluated and compared to the applicable future without project scenarios previously described in Chapter V. As previously noted, the six future without project scenarios combine various types of relative sea level rise with two types of redevelopment (see section 5.3 for more detail). The HEC-FDA model calculates damages reduced for a base year and a most likely future year and interpolates damages between the two points to determine equivalent annual damages. The model was set up so the exceedance probability function for the base year does not incorporate relative sea level and the function for the most likely future year does include the relative sea level rise adjustment. This allows the model to determine the damages between the two points.

Equivalent annual damages are calculated as:

Equivalent annual damages (EAD) = Present Worth of Total Damages x Capital Recovery Factor

Capital Recovery Factor (CRF) = i / (1-(1+i) ^-n)

Where:

i = interest rate

n = period of analysis

Figure 6.1-1 shows the linear interpretation used by HEC-FDA to calculate equivalent annual damages. The same methodology was used when converting projects recommended for construction to a 50-year period of analysis.

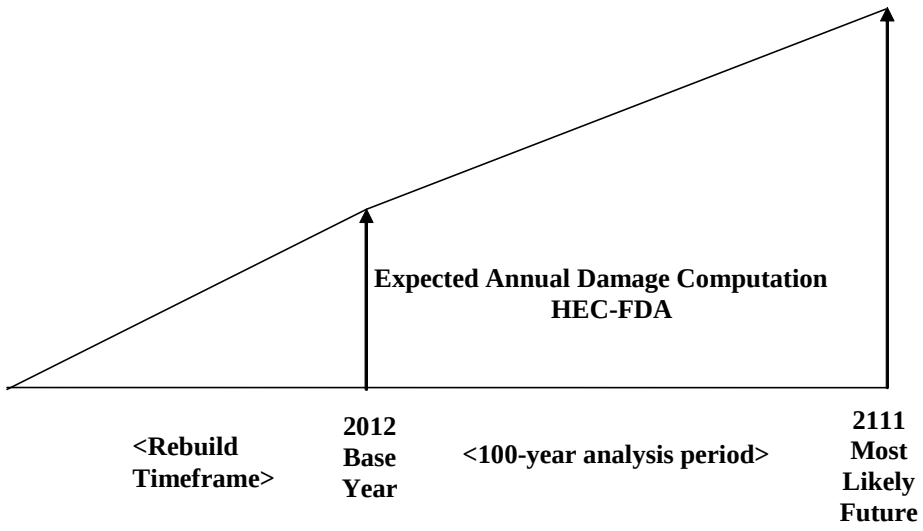

Figure 6.1-1. Linear Interpretation of Equivalent annual damages

6.1.2 Calculation of Costs

This section describes the use of cost estimates in the evaluation of the measures and alternatives. The methodology and application will be described here, and the sections describing the specific measures and alternatives at each site will show summaries of the costs. Detailed line item cost estimates can be found in the MsCIP Comprehensive Plan Cost Appendix.

6.1.2.1 Implementation Costs

Rough Order Magnitude (ROM) implementation costs were developed for each of the different measures and alternatives evaluated at each of the areas. The MOBILE DISTRICT Engineering Division developed the costs for structural measures and the Corps of Engineers Nonstructural Flood proofing Committee (NSFPC) developed the costs for the nonstructural measures. Savannah District Real Estate Division provided the real estate portions of each of the plans. All costs shown are in October 2007 price levels unless otherwise stated. Detailed cost estimates can be found in the cost estimating appendix to the MsCIP Comprehensive Plan Report.

6.1.2.2 Average Annual Implementation Costs

Average annual implementation costs were calculated for each of the measures and alternatives are calculated as:

Average Annual Implementation Cost = (Total Present Worth of Implementation Costs + IDC) x Capital Recovery Factor

Typically, costs are associated to the years they would be expended in should the project be constructed. Those expenditures are then brought back to the same fiscal year (FY) as the benefits in order for a direct and accurate comparison. This methodology was used for all measures and alternatives that will be recommended for construction. For those measures and alternatives that will be recommended for further study, the timing of expenditures have not yet been identified; therefore the total implementation cost act as the total present worth of the implementation costs and will be multiplied by the capital recovery factor to get the average annual implementation cost values.

Interest during construction is an added economic cost because it is the opportunity cost of having construction monies tied up until the measure becomes fully operational. Interest during construction was calculated based on the following formula:

$IDC^3 = \sum$ (Monthly Expenditure x Interest Rate Factor)

Monthly Expenditure = Implementation Cost / D

Interest Rate Factor = $(1+ I_M)$ ^ $(D – M)) - 1$

Where:

I_M = Interest Rate Factor = (Discount Rate / 12)

D = Total Construction Duration

M = Elapsed Time (Months) of Construction

Interest during construction was calculated for all measures and alternatives that will be recommended for construction. Due to the size and scope of the comprehensive effort, at this point in the analysis, the length of construction for many of the measures and alternatives has not been identified; interest during construction was not calculated for all of measures. Further study would be required in order to calculate interest during construction for those measures and alternatives not ready for construction recommendation. The main report details the measures and alternatives and their respective plan features.

[3] IDC was calculated based on Corps of Engineers National Economic Development Procedures Manual--Urban Flood Damage.

6.1.2.3 Operation and Maintenance Costs

Operation and Maintenance (O&M) costs were identified for each of the potential measures and alternatives. O&M costs for the structural solutions are described in the engineering appendix and the cost estimating appendix and are generally two-percent of the contract cost of the structure. O&M costs for the nonstructural measures and alternatives are described in the nonstructural appendix and are mostly based on the up keep of remaining lands associated with acquisition measures. All O&M costs shown for are annual costs and are typically borne by the local sponsor.

6.1.2.4 Total Average Annual Costs

Total average annual costs were calculated for each of the measures and alternative plans. Total average annual costs are the sum of the average annual implementation cost plus annual operation and maintenance cost.

6.1.3 Calculation of Regional Economic Development Benefits

This section describes the methodology and steps used to evaluate the regional economic development impacts attributable to each of the various measures and plans. The Economic Impact Forecasting System (EIFS) model was used in this analysis. Chapter III describes the background EIFS model. The methodology and application will be described here, and the sections describing the specific measures and alternatives at each site will show summaries of the costs.

6.1.3.1 Methodology

Impacts on business, employment, income, and population were evaluated using the Economic Impact Forecast System (EIFS), an economic analysis tool that, given the inputs for a particular project proposal, will asses potential impacts on four indicators of a local economy. EIFS is based on regional economic theory and provides regional economic analyses to planners and analysts. It draws information from a tailored socioeconomic database for any county in the United States. The database items are extracted from: Economic Censuses (wholesale, retail, services, and manufacturers), Census of Agriculture, the Bureau of Economic Analysis (BEA) employment and income time series, the BEA labor time series, and the County Business Patterns (CBP). The entire system-models, tools, and database-is then available to assess potential impacts on four indicators of a local economy: business volume, employment, personal income, and population.

6.1.3.2 EIFS Model Assumptions

EIFS assumes that the infrastructure pre-Katrina is intact, in-place, and functioning as a wholesome economic unit in the region of influence. The fact is that under existing conditions many of the established economic infrastructure is not present but transient. In some cases, rebuilt economic units have moved into fill that deficit to provide the goods and services. The assumption of this analysis assumes that the last or destroyed infrastructure will be rebuilt or replaced in the near-term and will not significantly reduce the impacts and outputs forecasted in this investigation.

6.1.3.3 Summary Explanation of the EIFS Model Inputs and Outputs

6.1.3.3.1 EIFS Model Inputs

The two data sources used as inputs for the EIFS model were the implementation cost and O&M cost for each of the measures and alternatives. Each of the cost inputs used was in present worth dollars, not average annual. Present worth costs were used because it is the actual estimated

amount that will be spent to implement, operate, and maintain the measure or alternative and that is what will drive the regional impacts.

6.1.3.3.2 EIFS Model Outputs

- Change in Sales Volume

Changes in local business activity include direct sales volume and induced volume. Direct sales volume is the change in the dollar value of sales in the retail and wholesale trade sector and receipts in the service sector resulting from local purchases by people as well as construction and procurement expenditures. Induced sales volume is the additional sales activity generated as a result of the direct change in sales.

- Income

Changes in income represent the wage and salary payments made to construction workers and to the resident workforce.

- Employment

Employment changes include both direct and indirect changes, as well as short and long term changes. The direct long-term change in local employment is the increase in employment associated with construction. Subsequent indirect increases in employment are produced by the multiplier effect resulting from increased spending by the additional staff and construction employees.

6.2 Evaluation of Barrier Island Measures

6.2.1 General Description

The coastline of mainland Mississippi is bordered on the south by the Mississippi Sound, a shallow body of water that separates the coast from four barrier islands that lie several miles to the south. These barrier islands are located along a littoral drift zone that moves sand westward creating three elongated islands and then westward toward Cat Island, where littoral currents are not as well defined. Cat Island has a different origin than the other islands and is a remnant of a lobe of the St. Bernard Delta that was created by the Mississippi River. Wave action has created a beach on the eastern side of the island forming a distinctive T-shape. From west to east, the islands are Cat, Ship (now actually two islands, West and East Ship Island), Horn and Petit Bois. The western ends of both Petit Bois and Ship Islands have migrated to maintained navigation channels and the continuing littoral drift of the sand into the channels is causing an artificial termination of the migration. A new island has emerged on the west side of the channel from Petit Bois Island, created from the dredged sand coming from island that is disposed of on the west side of the channel.

6.2.1.1 Location

The barrier islands of Mississippi are located 10 to 15 miles south of the mainland. Currently, there are five islands in the chain that extends for 45 miles west from a point south of the Alabama – Mississippi state line along the coast. Currently, Ship Island exists as two islands separated by a shallow sand bar. It was breached during Hurricane Camille in 1969 and remains today as West and East Ship Island. Two maintained navigation channels pass through the chain of islands. The Gulfport channel passes near the west end of West Ship Island and the Pascagoula channel passes near the end of Petit Bois Island. The present day location of the channels prevents any further westward migration of either island.

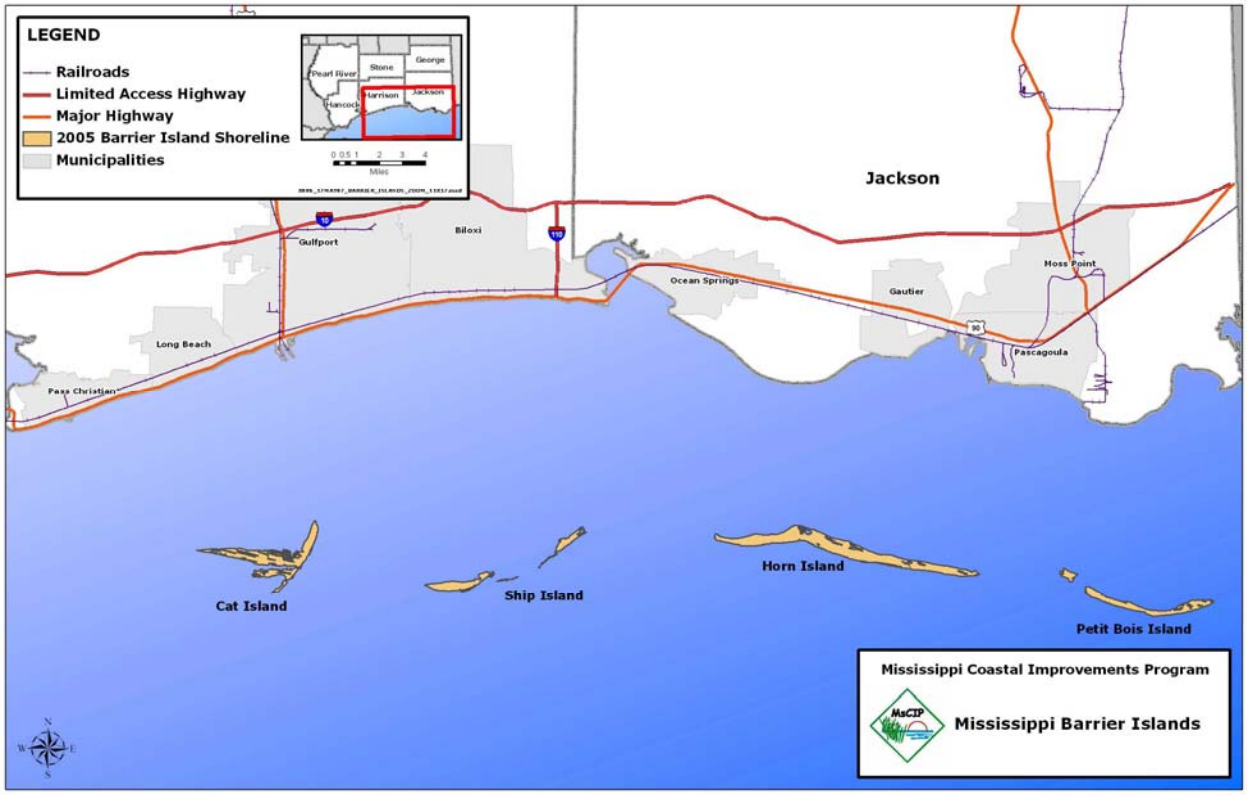

Figure 6.2.1-1. Location of the Mississippi Barrier Island

6.2.1.2 Historic Conditions (Pre-Hurricane Katrina)

6.2.1.2.1 Historic Fisheries

The value of the fisheries that are harvested from the Mississippi Sound has been an integral aspect of the local economy for decades. The industry has seen a significant rise in value since the 1970's, as is shown in table 6.2-1. The table and figure also show the effects of increased salinity on the system.

Table 6.2-1.
Historic Landings and Value of All Fisheries from Mississippi Sound

Year	Metric Tons	Pounds	% Change Pounds Since 1975	Value ($)	% Change Value ($) Since 1975
1975	138,690.7	305,757,600	N/A	$14,347,114	N/A
1976	130,708.7	288,160,500	-3%	$21,008,332	89%

6.2.1.3 Existing Condition (Post-Hurricane Katrina)

6.2.1.3.1 Damage to Structures

The three coastal Mississippi counties suffered tremendous devastation from Hurricane Katrina's surge. It is estimated that 32,446 structures were significantly destroyed (at least fifty-percent or more), with another 15,000 to 25,000 suffering moderate to minimal inundation damage. Of the structures sustaining significant destruction, 9,555 were in planning unit one, 16,528, in planning unit two, and 6,363 in planning unit three. Of those significant loss structures, approximately 19,000 claims were paid out by the Federal Emergency Management Agency's (FEMA's) National Flood Insurance Program (NFIP) totally over $2.3 Billion dollars, with the average claim around $137,000. Currently, no accurate data exists for uninsured losses, but estimates range in the billions of dollars. Table 1 displays the significantly damaged structures by planning unit and by structure category. Table 6.2-2 shows the severely damaged structure by planning unit.

Table 6.2-2.
Structures Damaged 50% or More by Planning Unit and by Category

	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Commercial	1,267	1,794	378	3,439
Residential	8,099	14,500	5,780	28,379
Municipal	127	89	136	352
Mobile Home	62	145	69	276
Total	**9,555**	**16,528**	**6,363**	**32,446**

Source: Estimated from field inventory cluster sampling.

6.2.1.3.2 Damage to Barrier Islands

Immediately following Hurricane Katrina, most of the effort was spent protecting human life and securing structures throughout the impacted areas on the mainland; therefore, few assessments of the vegetation impacts exist, especially on the barrier islands. For the barrier island system, most all of the marsh vegetation recovered several months following Hurricane Katrina. The predominant vegetation that has long-term impacts consists of those pines found in the maritime forests. It is estimated that about 75% of these pine species were killed following the hurricane season of 2005, with most that attributable to Hurricane Katrina. The emergent marsh habitat is thriving so well it actually looks as though hurricanes never past through the barrier island system. The sea oats are still found in small patches due to the reduced dune system. Any measure that includes the planting of marsh vegetation will have to consider the current population of nutria that inhabits the islands. These exotic animals from South America can destroy attempts to establish marsh planting and any program should include the control of these rodents.

As is typical of most barrier island systems, the Mississippi islands are an ever-changing and dynamic landscape. Data shows that the islands have lost approximately 20 to 25 percent of their land mass since pre-Camille times. The islands have been heavily influenced by the various hurricanes including even the lower intensity ones. Hurricane George, in 1998, even though a small hurricane, proved to be devastating to the islands due heavy erosion from waves. Many of the higher dunes systems on the islands were destroyed and much of the elevation the islands once had is gone. Most of the islands are now very susceptible to over-wash during storms. Another result of being submerged during Hurricane Katrina was the loss of much of the maritime pine forest that existed on the islands. The trees, mostly now dead from the salt water submergence, played a major role in preventing erosion both from wind and any surges against the islands.

Figure 6.2.1-2. Photo of the south beach at Horn Island. Pre-existing dunes have been destroyed by numerous hurricanes over the last several years

6.2.1.2 Without-Project Condition

6.2.1.2.3 Equivalent annual damages

As previously described in Chapter V, six future without-project scenarios were developed, based on the existing condition characteristics, for the evaluation of future without-project conditions. The six scenarios were evaluated over a 100-year period of analysis from the base year 2012 (2012–2111) and using the FY08 federal discount rate of four-and-seven-eighths (4.875) percent. The six future scenarios include two redevelopment scenarios (residential and mixed-residential and commercial) and three relative sea level rise scenarios (base sea level, expected relative sea level rise, and high relative sea level rise) for a total of six different future scenarios. Scenario one is a residential redevelopment with no relative sea level rise over the 100-year period of analysis, scenario two is a mixed residential and commercial redevelopment with no relative sea level rise, scenario three is a residential redevelopment with an expected relative sea level rise, scenario four is a mixed residential and commercial redevelopment and an expected relative sea level rise, scenario five is a residential redevelopment with a high relative sea level rise, and scenario six is a mixed residential and commercial redevelopment with a high relative sea level rise. Table 6.2-3 shows the equivalent annual damages for the six future without-project scenarios.

Table 6.2-3.
Equivalent Annual Without-Project Damages by Planning Unit and Future Scenario

Without-Project Damages	Future 1[2] Damages	Future 2[2] Damages	Future 3 Damages	Future 4 Damages	Future 5 Damages	Future 6 Damages
Planning Unit One	$198,960,000	$202,060,000	$218,050,000	$222,220,000	$237,310,000	$241,520,000
Planning Unit Two	$91,260,000	$94,680,000	$103,280,000	$107,120,000	$115,470,000	$119,760,000
Planning Unit Three	$88,670,000	$88,670,000	$104,700,000	$104,700,000	$122,420,000	$122,420,000
Total	**$378,890,000**	**$385,410,000**	**$426,030,000**	**$434,040,000**	**$475,200,000**	**$483,700,000**

Damages are rounded to the nearest ten thousand.
1 Futures Two, Four, and Six do not apply to planning unit three, therefore total damages are the same as future scenarios one, three, and five.
2 Future Scenarios one and two will be used to evaluate the impacts of relative sea level rise only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

These equivalent annual without-project damages are those that would be expected to occur over the period of analysis should the barrier islands remain in their existing state, however, recent data collected by the USGS, and analysis of historical data by the Corps and others, suggests that this may not be the case. The long-term trends exhibited by the Barrier Islands and wetlands of Louisiana, and the coastal areas of Alabama and the panhandle of Florida, suggest that the regional sediment budget of the Northern Gulf of Mexico is not sufficient to restore and/or maintain these areas in their existing condition. Although no one study or investigator has suggested a time frame for the demise of these features, it is increasingly evident that their effectiveness at reducing storm surge and wave energies has been reduced significantly in the last 50 years. This has been exhibited most dramatically after Katrina in reduction of Barrier Island extent [note – look at Bob Morten's report].

Unfortunately, due to severe timing and funding constraints pertaining to the MsCIP Comprehensive Plan and the complexity of modeling various states of the barrier islands, only a sensitivity analysis was conducted to roughly capture the increased inundation risk of the further degradation of the islands. The data from that sensitivity analysis indicates that further loss of the barrier islands could result in as much as ten-feet of additional wave damage to structures and their contents. This loss of surge protection could actually increase the total equivalent annual damages over the project life by as much as an additional eight to nine-percent. Table 6.2-4 displays the anticipated effects of increased damages due to further loss of the barrier islands.

Table 6.2-4.
Increase in Equivalent Annual Without-Project Damages by Planning Unit and Future Scenario due to Further Degradation of the Barrier Islands

Without-Project Damages	Future 1[2] Damages	Future 2[2] Damages	Future 3 Damages	Future 4 Damages	Future 5 Damages	Future 6 Damages
Planning Unit One with Islands	$198,960,000	$202,060,000	$218,050,000	$222,220,000	$237,310,000	$241,520,000

Total $ Increase without Islands	**$15,058,200**	**$15,297,600**	**$17,699,600**	**$17,968,400**	**$20,324,900**	**$20,625,200**

Damages are rounded to the nearest ten thousand.
1/ Futures Two, Four, and Six do not apply to planning unit three, therefore total damages are the same as future scenarios one, three, and five.
2/ Future Scenarios one and two will be used to evaluate the impacts of relative sea level rise only, and will not be discussed in the direct evaluation of potential measures detailed in Chapter IV of this appendix.

6.2.1.2.3 Loss of Fisheries

Marine resources harvested from the Mississippi Sound are crucial to the economy of the three coastal counties and the state of Mississippi. It is estimated that in 2004, approximately 4,800 jobs and $300 million in gross annual revenue were dependent on fisheries from the sound. Various species harvested include oysters, bluefish, drum sea trout, sea catfish, white and brown shrimp, mullet, and snapper. According to National Marine Fisheries, total landings in 2004, the most accurate pre-Katrina data available, included 83,262 metric tons (183,558,261 pounds) for an estimated landing value of $43,618,143. In 2004, oyster production from the Mississippi Sound accounted for 8-percent of national oyster production and 11-percent of eastern oyster production. Comparison of pre-Katrina and post-Katrina landings provides a sharp comparison of what Mississippi Sound provided the State of Mississippi in terms of economic benefits, and what was lost as a result of the hurricane.

Comparison of the nearest full year (use of 2005 is problematic due to the fact that the hurricanes occurred mid-year) of monetary benefits due to commercial fish and shellfish landings, on either side of the hurricanes of 2005, provides the following insight into losses caused by those hurricanes. Table 6.2-5 shows an example of the devastating impacts of increased salinity in the Mississippi Sound due to Hurricane Katrina. If the islands continue to degrade, a point will be reached where the

salinity would kill the entire oyster and shrimp harvesting and the majority of all other existing fisheries as well. More detail about the devastating impacts of island degradation can be found in the environmental appendix.

Table 6.2-5.
Loss of Shrimp, Oysters, and other Species Due to Hurricane Katrina

Species	2004	2006	Loss
Shrimp	$26,353,576	$11,854,449	$14,499,127
Oysters	$6,073,242	$1,447,132*	$4,626,110
All Species Listed Above	$43,618,143	$21,741,108	$21,877,035

6.2.1.2.4 Loss of Recreation

This section describes the without-project recreation conditions for the barrier islands, which are the continued degradation of the islands and loss of all recreational use as a result of the continued degradation. Typically, recreational uses on the islands include general recreation such as boating, sightseeing, picnicking, swimming, and fishing from banks and boats. Additionally, the western portion of Ship Island, known as West Ship Island, is the home to two historic sites; Fort Massachusetts and the French Warehouse. Ship Island, the second island from the west in figure 6.2.1-1 above, was split into two islands by Hurricane Camille.

Visitors attend West Ship Island by using a commercial company called Ship Island Excursions or privately owned recreation boats. The island and facilities are run by the National Park Service. Table 6.2-6 below shows annual statistics estimated by the Park Service from 1989 through 2006.

Table 6.2-6.
Annual Ship Island Visitation

Year	Annual Visitation	Change from Previous Year (%)
1989	45,386	N/A
1990	54,661	20.436%
1991	49,301	-9.806%
1992	51,623	4.710%
1993	49,432	-4.244%
1994	51,059	3.291%
1995	53,793	5.355%
1996	59,724	11.026%
1997	58,969	-1.264%
1998	59,917	1.608%
1999	65,657	9.580%
2000	66,609	1.450%
2001	63,059	-5.330%
2002	62,720	-0.538%
2003	65,327	4.157%
2004	62,135	-4.886%
2005	41,453	-33.286%
2006	20,340	-50.932%

As the table shows, annual attendance to West Ship Island was relatively stable until the Island was impacted by Hurricane Katrina. Attendance in 2006 plummeted by more than 67-percent from its 2004 pre-Katrina level. The average yearly attendance for the five year period pre-Hurricane Katrina (2000-2004) was 63,970 visitors. Since there is little other data available on the recreational use of the barrier islands, and due to the timing constraints of this study, this number was used to estimate the annual recreational use.

Based on 63,970 annual user days, a unit day value (UDV) analysis was conducted to determine the monetary recreational value of use of the barrier islands. The UDV method relies on expert or informed opinion and judgment to estimate the average willingness to pay of recreational users. Interviews conducted pertaining to the without-project condition relied on expert or informed opinion and judgment to approximate the average willingness to pay of users of West Ship Island.

The guidelines for assigning points to general recreation include five categories:

- The quality of the recreational experience as affected by congestion,
- Availability of substitute areas in terms of travel time,
- Carrying capacity determined by level of facility development,
- Accessibility as affected by road and parking conditions, and
- Environmental quality based on aesthetics.

A resource is then rated on a 100-point scale. The total possible points that can be assigned to each criterion are as follows:

- Recreational Experience – 30,
- Availability of Opportunity – 18,
- Carrying Capacity – 14,
- Accessibility – 18, and
- Environmental - 20.

The conversion of points to dollar values for general recreation is expressed in two activity categories: general recreation and general fishing and hunting. Hence, points are expressed in the same manner. Therefore, for this project, general recreation includes boating, sightseeing, picnicking, swimming, and the visitation of the historical Fort Massachusetts and the French Warehouse. General fishing and hunting includes fishing from banks and boats. Table 6.2-7 summarizes the point value system as defined by EGM 08-02.

Table 6.2-7.
Guidelines for Assigning Points for General Recreation

Criteria	Judgment Factors				
Recreation experience[1] **Total Points: 30**	Two general activities[2]	Several general activities	Several general activities; one high quality value activity[3]	Several general activities; more than one high quality value activity	Numerous high quality value activities; some general activities
Point Value:	0-4	5-10	11-16	17-23	24-30
Availability of opportunity[4] **Total Points: 18**	Several within 1 hr. travel time; a few within 30 min. travel time	Several within 1 hr. travel time; none within 30 min. travel time	One or two within 1 hr. travel time; none within 45 min. travel time	None within 1 hr. travel time	None within 2 hr. travel time
Point Value:	0-3	4-6	7-10	11-14	15-18
Carrying Capacity[5] **Total Points: 14**	Minimum facility for development for public health and safety	Basic facility to conduct activity(ies)	Adequate facilities to conduct without deterioration of the resource or activity experience	Optimum facilities to conduct activity at site potential	Ultimate facilities to achieve intent of selected alternative
Point Value:	0-2	3-5	6-8	9-11	12-14
Accessibility **Total Points: 18**	Limited access by any means to site or within site	Fair access, poor quality roads to site; limited access within site	Fair access, fair road to site; fair access, good roads within site	Good access, good roads to site; fair access, good roads within site	Good access, high standard road to site; good access within site
Point Value:	0-3	4-6	7-10	11-14	15-18
Environmental **Total Points: 20**	Low aesthetic factors6 that significantly lower quality[7]	Average aesthetic quality; factors exist that lower quality to minor degree	Above average aesthetic quality; any limiting factors can be reasonably rectified	High aesthetic quality; no factors exist that lower quality	Outstanding aesthetic quality; no factors exist that lower quality
Point Value:	0-2	3-6	7-10	11-15	16-20

Table 6.2-8 shows the average respondent values for the value of recreational use of the barrier islands. Notes from those interviews include overwhelming high aesthetic value, general uses except for the ability to visit the historical Fort Massachusetts and French Warehouse, fair to good accessibility, and adequate to optimum facilities at the site.

Table 6.2-8.
Point Value of Recreational Use

	Recreational Experience	Availability of Opportunity	Carrying Capacity	Accessibility	Environmental	Totals
Average Respondent	10.00	3.00	8.00	10.00	20.00	**51.00**

Table 6.2-9 shows the conversion of points to FY 2008 dollar based on EGM 08-02.

Table 6.2-9.
Point Value of Recreational Use

Point Values	General Recreation Values	General Fishing and Hunting Values	Specialized Fishing and Hunting Values	Specialized Recreation Values other than Fishing and Hunting
0	$3.40	$4.89	$23.81	$13.82
10	$4.04	$5.53	$24.44	$14.67
20	$4.46	$5.95	$24.87	$15.73
30	$5.10	$6.59	$25.51	$17.00
40	$6.38	$7.23	$26.14	$18.07
50	$7.23	$7.86	$28.69	$20.40
60	$7.86	$8.71	$31.24	$22.53
70	$8.29	$9.14	$33.16	$27.21
80	$9.14	$9.78	$35.71	$31.67
90	$9.78	$9.99	$38.26	$36.13
100	$10.20	$10.20	$40.38	$40.38

Table is from EGM 08-02 "Unit Day Values for Recreation, Fiscal Year 2008"

The general recreation score of 51 translates to unit day value of $7.29. The average annual benefits were calculated by multiplying the UDV by the annual visitor occasions. Using the estimated 63,970 annual users and the interpolated $7.29 unit day value, the average annual recreation loss of continuing to allow the islands to degrade is $466,341

6.2.2 List of Measures

Measure A – Restore Island Footprint

The pre-Camille footprint of the islands was obtained from historical records and the amount of area that has been lost to coastal erosion since that time was computed. Without accurate topography of the islands and an assumption was made that some dunes had a top of elevation of 20 feet NAVD88. It should be noted that some of the islands have migrated and any reconstruction would be to increase their footprint at their present location and not move them back to historical locations.

Several approaches to restoration of the islands were considered. This measure will only include new land mass that is being added to the islands by using sand dredged and transported from an off-shore location. The shaping of the sand into beaches, dunes and marsh areas will not affect the existing islands other than that narrow strip of land that will form the boundary between the existing island and the new land mass. This measure can be used in combination with other measures under this line of defense should it be desired to restore habitat on the existing islands.

Restoration of Ship Island to a pre-Camille configuration includes closing the post-Katrina, 3-mile long breach to a 2000-foot width and with elevation 20.0-foot NAVD88 dunes, along with some rebuilding of the other islands to a larger land area. The land mass of each of the islands was estimated in a pre-Hurricane Camille condition using historical aerial photography.

Measure B – Replenish Sand in Littoral Zone, Inland Source

Another consideration to help restore the islands is to supplement the sand in the littoral system. This could be accomplished by adding sand in specific locations based on sediment transport modeling. This would allow the littoral currents to move the sand onto the islands where the natural process of island building could take place. This would not directly affect the present-day islands and would help mitigate any effects of dredging the ship channels that pass through the chain of islands where sand may have been lost from the system.

The construction of inland waterways in Alabama and Mississippi has resulted in continuing maintenance dredging to maintain the channel depths and alignments. Dredging of some of the areas along the river has produced large quantities of sand that have potential use for replenishment of littoral zones such as are found along the Mississippi Barrier Islands. This dredged material, approximately 30 million cubic yards, is now accumulated in disposal areas along the banks of the rivers.

Measure C – Replenish Sand in Select Littoral Zones, Offshore and Inland River Sources

Another consideration to help restore the islands is to supplement the sand into specific areas of the littoral system with sand obtained from both Inland and offshore borrow areas. Like Measure B, this could be accomplished by adding sand in specific locations based on sediment transport modeling. The general locations for this measure were based on islands that have migrated westward to alignments of maintained navigation channels causing an artificial termination of further migration. Placing sand into these locations would allow the littoral currents to move the sand onto the islands where the natural process of island building could take place. While this process would not directly affect the present-day islands, it would help mitigate any effects of dredging the ship channels that pass through the chain of islands where sand may have been lost from the system. The sand that could be used in this measure may come from the same offshore borrow area as Measure A, the St. Bernard Shoals located about 45 miles south of the barrier islands as well as the inland river systems as described in Measure B.

Measure D – Environmental Restoration w/ 2-foot Dune

This measure would involve environmental restoration of the islands consisting of shaping existing sand into low dunes on the beaches with planted vegetation and planting of maritime forests on the existing islands where they were mostly destroyed by Hurricane Katrina.

Despite continual changes that occur, the barrier islands remain to buffer the mainland from storms and provide habitat for the rich, diverse wildlife residing within the area. On the southern portion of the islands, sea oats primarily, which are tolerant of high salt levels, thrive on the dune system which is located behind the beach area. Behind the primary dunes, trees and shrubs, such as short-leaf and long-leaf pines, can be found in the maritime forest. In the island interiors, emergent marshes collect fresh rainwater to help support its inhabitants

A restoration measure with the least impact on the existing post-Katrina islands would be to re-establish the vegetation that was destroyed. This measure could involve restoration of the existing islands through adding sand dunes on the beaches along with planted vegetation (i.e. *Uniola paniculata*), planting of marshes (i.e. *Spartina alterniflora*, *Juncus roemerianus*, and *Spartina patens*) and maritime forests (i.e. *Pinus elliottii Engelm*, *Serenoa repens, Sabal minor*, etc.), and planting sea grasses (i.e. *Diplanthera wrightii, Cymodocea manatorum, Thalassia testudinum*, and *Ruppia maritime*) in the near-shore areas of the islands. Foremost, the vegetation would restore the island's natural setting, which allows for the diverse array of flora and fauna to persist. This plan would not involve adding any land mass to the islands other than the possibility of adding to the dune system. Vegetation would aid in reducing erosion from wind; thus helping in maintaining the stability of the

islands. The vegetation would also aid in preventing erosion in the event that the islands gets overtopped by storm surge in a large hurricane.

Measure E – Environmental Restoration w/ 6-foot Dune

This measure would involve environmental restoration of the islands consisting of adding sand onto the existing beaches in sufficient quantities to construct a dune approximately 6 feet high. The dunes on the beaches would be planted with vegetation along with the planting of maritime forests on the existing islands where they were mostly destroyed by Hurricane Katrina. The sand required to construct a dune of this size would be more than could be removed from the existing beach berm and would come from the same offshore borrow area as the sand used in Measure A. Placement of the sand would require moving the sand from a hopper dredge to a staging area on the beach, then moving the sand to the area of placement along the beach.

Measure F – Environmental Restoration of Sea Grass Beds

This measure would involve environmental restoration of the sea grass beds that have historically existed on the north side of the islands in the Mississippi Sound. Knowledge of submerged aquatic vegetation (SAVs) is limited to reports by Humm (1956) and Humm and Caylor (1957) before the Gulf of Mexico Estuarine Inventory (GMEI) Study (1973). They reported the occurrence of five flowering species known as “seagrasses” and 77 algal species all along the Mississippi barrier islands. Studies carried out by the GMEI personnel revealed that there were about 17,000 acres of SAVs in Mississippi Sound prior to Hurricane Katrina. Information obtained from MDMR indicated that since Hurricane Camille in 1969, 8,800 acres of SAVs have been lost. Using maps from MDMR, fifty percent of the total lost acreage would be replaced throughout the previous range to help restore this valuable habitat under this measure.

Measure G – Restore Ship Island Breach

The most predominate affect of Hurricane Katrina on the Mississippi Barrier Islands was the large increase in size of the breach in Ship Island commonly known as the Camille Cut. The pre-Camille footprint of Ship Island was obtained from historical records. This data showed the area that was breached during Hurricane Camille forming two separate islands. West and East Ship Island has two major historic sites that are in danger from the continuing erosion of the barrier islands. Current studies by the Corps indicate that restoring the two islands to a single island, pre-Camille condition may prevent the rapid erosion of the beaches that is now occurring as well as helping to provide wave erosion on the mainland. Estimates indicated that the total restoration of Ship Island to a single land mass off the Mississippi coast will involve approximately 8 million cubic yards of sand. As happened during Hurricane Camille, the breach was opened during Hurricane Katrina leaving two islands with approximately three miles of open water between the remaining portions. This portion of the island has also been breached during other prior hurricanes and while most of the island has reformed to a low bar over time, it never gained enough sand to form dunes and establish vegetation along this center portion.

Fort Massachusetts is located on the northern shore of West Ship and the French Warehouse is located on the northern shore of East Ship Island. Both of these sites are endangered by on-going erosion of the shoreline with Mississippi Sound. Another site, known as the Quarantine Station, has already been lost to erosion.

Measure H – Comprehensive Measure

This plan is a physical implementation combination of measures C and G.

6.2.3 With-Project Conditions

The benefits attributable to the proposed barrier island measures are those avoided future losses should no action be taken. Implementation of the measures would result in the avoidance of increased surge damages due to amplified wave attack, the preservation of the Mississippi Sound habitat that is vital to both local fisheries and economies, but also a large source of national oyster production, and the continued use of the barrier islands as a recreational resource. Table 6.2-10 shows the estimated NED benefits for each of the barrier island measures and table 6.2-11 shows the EQ benefits by measure. Benefits were quantified where possible and are based on expert elicitation from six interviews conducted with project delivery team members and knowledgeable federal and state agency contacts.

Table 6.2-10.
NED Benefits by Measures

Measures	Future 3 Avoidance of Increased Surge Damage (Annual $)	Future 4 Avoidance of Increased Surge Damage (Annual $)	Future 5 Avoidance of Increased Surge Damage (Annual $)	Future 6 Avoidance of Increased Surge Damage (Annual $)	Avoidance of Recreation Loss (Annual $)
	NED Benefits				
(No Action)	$0	$0	$0	$0	$0
Measure A	$17,699,600	$17,699,600	$17,699,600	$17,699,600	$466,341

1/ Estimates are based on expert or informed opinion and judgment to estimate the extent of the losses avoided in each category.

6.2.4 Summary of Costs

Table 6.2-12 summarizes the rough order magnitude (ROM) costs for potential barrier island measures. IDC was calculated based on a five-year (60 month) construction duration and the FY08 discount rate of 4-7/8-percent. Average annual costs are based on the 4-7/8-percent discount rate and a 100-year period of analysis. There are no estimated direct costs for annual operation and maintenance; however, a maintenance plan does exist and is detailed in the barrier island appendix.

Table 6.2-12.
Total Average Annual Costs by Measure

Measures	Total Implementation Cost ($)[1]	IDC ($)	Total First Cost ($)	Average Annual First Cost ($)	Average Annual O&M Cost ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A	$942,200,000	$119,317,000	$1,061,517,000	$53,431,000	$0	$53,431,000
Measure B	$1,013,800,000	$128,383,000	$1,142,183,000	$57,491,000	$0	$57,491,000
Measure C	$147,400,000	$18,667,000	$166,067,000	$8,359,000	$0	$8,359,000
Measure D	$14,200,000	$1,798,000	$15,998,000	$805,000	$0	$805,000
Measure E	$39,200,000	$4,965,000	$44,165,000	$2,223,000	$0	$2,223,000
Measure F	$264,500,000	$33,495,000	$297,995,000	$14,999,000	$0	$14,999,000
Measure G	$181,400,000	$22,972,000	$204,372,000	$10,287,000	$0	$10,287,000
Measure H	$328,800,000	$41,639,000	$370,439,000	$18,646,000	$0	$18,646,000

1/ Numbers are rounded to the nearest thousand and are based on ROM costs at an FY-08 price level. The cost estimating appendix shows these in more detail, as well as MCACES costs for the tentatively-recommended plan.

6.2.5 Regional Economic Development (EIFS Model)

The purpose of this analysis is to determine the economic impact of the proposed project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local areas of Jackson County, Harrison County and Hancock County Mississippi. The expenditures for the measures are estimated to be $942,200,000 for Measure A, Restore Island Footprint measure, $1,013,800,000 for Measure B, Replenish Littoral Zone (river sand) measure, $147,700,000 for Measure C, Replenish Littoral Zone (offshore sand) measure, $14,200,000 for Measure D, 2-foot Dune with beach sand measure, $39,200,000 for Measure E, 6-foot Dune with plantings measure, $264,500,000 for the Measure F measure and $181,400,000 for Measure G, Restore Ship Island measure. Tables 6.2-10 and 6.2-11 summarize the EIFS model inputs and outputs for the Barrier Island Measures.

Table 6.2-13.
EIFS Model Inputs for Barrier Island Measures

	Measure A	Measure B	Measure C	Measure D	Measure E	Measure F	Measure G	Measure H
Region of Influence (ROI)	Three Counties	Three Counties	Three Counties	Three Counties	Three Counties	Three Counties	Three Counties	Three Counties
Change in Local Expenditures	$942,200,000	$1,013,800,000	$147,400,000	$14,200,000	$39,200,000	$264,500,000	$181,400,000	$328,800,000

Based of the given inputs the outputs are as followed:

Table 6.2-14.
EIFS Model Outputs for Barrier Island Measures

	Measure A	Measure B	Measure C	Measure D	Measure E	Measure F	Measure G	Measure H
Direct Sales Volume	$942,200,000	$1,013,800,000	$147,400,000	$14,200,000	$39,200,000	$264,500,000	$181,400,000	$328,800,000

6.3 Evaluation of Beach and Dune Construction Measures

6.3.1 Planning Unit One

6.3.1.1 Background

The beaches of Hancock County are approximately 9 miles in length, and host one of the Gulf Coast's largest populations of Least Tern, a Federally-listed endangered species, plus a significant number of Piping Plover. The beaches possessed a vegetated dune system (pre-Katrina) that was maintained by local interests and supported a significant ecosystem, in addition to passive recreation usage outside the dune system. This dune system provided not only ecosystem benefits, but some measure of hurricane or storm damage reduction due to its ability to absorb some of the surge and wave energy during those types of events. During Hurricane Katrina, this dune system was almost entirely destroyed by surge and wave action. Almost all ecosystem functions and values were eliminated during this single event. Much of the sand removed is believed to be close off shore in the near shore zone. The MsCIP Interim Chiefs Report recommended that a beach and dune placement project be constructed in planning unit one. The interim project consists of the following: (1) replacing approximately 43,800 cubic yards of lost sand dune material, (2) placing 37,000 linear feet of stabilizing sand fence, and (3) planting 19.3 acres of dune vegetation. Figures 6.3-1 and 6.3-2 show the project location and extent for planning unit one.

6.3.1.1.1 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation
- Preservation of Fish & Wildlife and restoration of their habitats
- Prevention or remediation of erosion
- Other related water resource purposes, such as ecosystem restoration or barrier island restoration

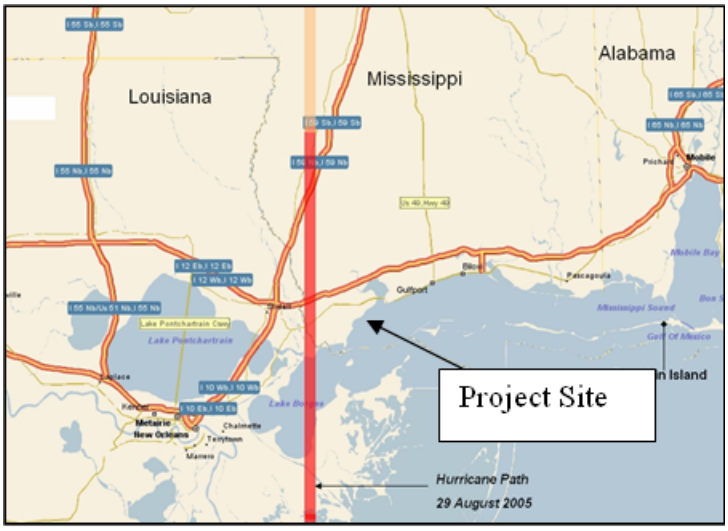

Figure 6.3-1. Project Sites for LOD2 in Planning Unit One

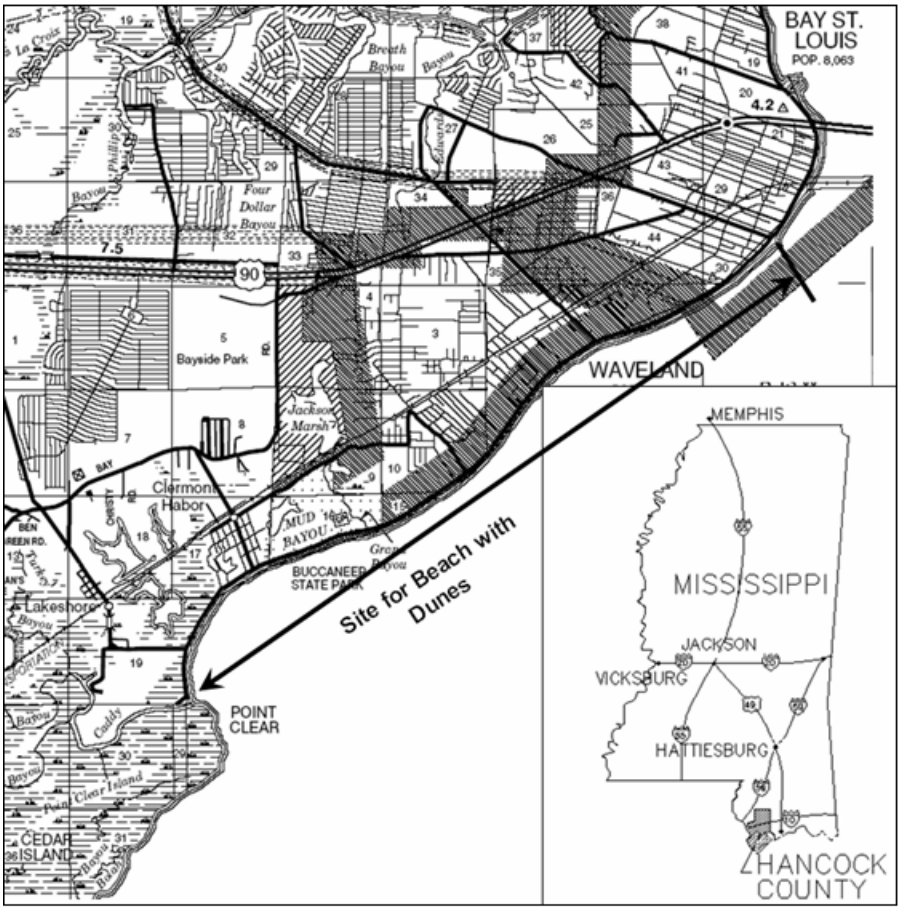

Figure 6.3-2. Project Limits for Line of Defense 2 in Planning Unit One

6.3.1.2 General Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs,
- Price levels are October, 2007 unless otherwise stated,
- A 50-year period of analysis was used to calculate average annual benefits and costs.

6.3.1.3 Measures

Eleven measures were evaluated for enhanced beach protection at the study site. All involve providing a dune and berm to the location. Some of the measures, Measures A through H described below, can not be constructed without the construction of the Seawall and Elevated roadway measure, which is evaluated in great detail later in this appendix. The measures for Line of Defense 2 in planning unit one are as follows:

- Measure A consists of a 10.0 feet NAVD88 dune elevation, 40.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.
- Measure B consists of an 8.0 feet NAVD88 dune elevation, 50.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.
- Measure C consists of a 10.0 feet NAVD88 dune elevation, 20.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.
- Measure D consists of an 8.0 feet NAVD88 dune elevation, 30.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.
- Measure E consists of a 10.0 feet NAVD88 dune elevation, 40.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows starting at the seaward toe of the dune. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.
- Measure F consists of an 8.0 feet NAVD88 dune elevation, 50.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows starting at the seaward toe of the dune. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.

- Measure G consists of a 10.0 feet NAVD88 dune elevation, 20.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows starting at the seaward toe of the dune. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure.

- Measure H consists of an 8.0 feet NAVD88 dune elevation, 30.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of starting at the seaward toe of the dune. This measure is dependent on the elevated roadway and seawall and could not be implemented as a stand alone measure. Figure 6.3-3 shows a typical cross section for Measures A though H.

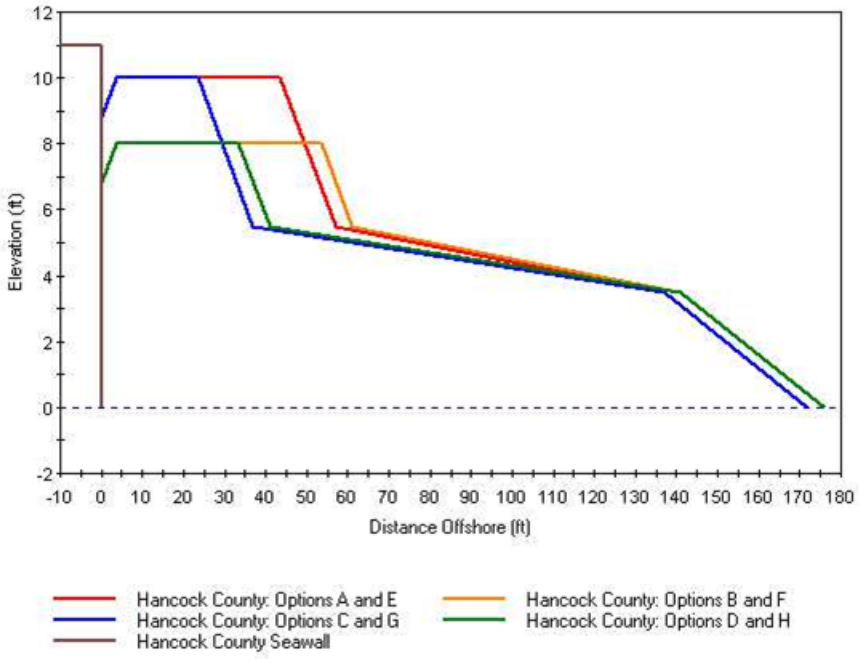

Figure 6.3-3. Typical Cross Section for Measures A through H

- Measures I and J are comparative with-project measures, for future evaluation, consisting of a design cross-section which includes a dune and berm constructed as a stand alone project which does not incorporate the Line of Defense 3 seawall. Measure I consists of a dune feature constructed approximately 50.0 feet seaward of the seawall at an elevation of 10.0 feet NAVD 88, with a crest width of 55.0 feet, and a dune slope of 1:3. The berm width would be extended to accommodate the placement of the dune feature. Sand fencing would be placed on the dunes to reduce sand transport due to the strong winds which frequently occur during storms. The cross section for Measure J is the same as Measure I; however the dune would be planted to provide for additional environmental habitat. For Measure J, sea oats would be planted on both the landward and seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of planted starting at the landward and seaward toes of the dune. The dunes will require initial and continued maintenance of vegetation and sand fencing. These measures are intended to be stand alone and are not dependent on the elevated roadway and seawall that is described in section 6.4.

- Measure K is also a measure for future evaluation which consists of an elevated berm section constructed primarily for the creation of environmental habitat. Measure K would be constructed as a stand alone measure which does not incorporate the Line of Defense 3 seawall. The elevated berm section would be constructed approximately 50.0 feet seaward of the existing seawall to an elevation 2.0 feet NAVD88 above the existing berm with a width of approximately 60.0 feet. The berm width would not be extended to accommodate the placement of the elevated berm feature. The new feature would be vegetated and sand fencing would be placed to create environmental habitat and to reduce sand transport due to the strong winds which frequently occur during storms. For Measure K, sea oats would be planted in a 30 by 30 inch grid pattern over the entire elevated berm area. The new feature will require initial and continued maintenance of vegetation and sand fencing. This measure is intended to be a stand alone and is not dependent on the elevated roadway and seawall that is described in section 6.4.

6.3.1.4 National Economic Development (NED)

This section describes the National Economic Development benefits for the various beach and dune placement measures in planning unit one that are attributable to hurricane and storm damage reduction. National economic development benefits are damages to structures and their contents that are reduced when a measure or alternative is implemented, or the difference between the with-project and without-project conditions.

There are two types of beach and dune placement measures for planning unit one; those that are dependent on the seawall and elevated roadway and those that can be implemented as stand alone measures. Those measures dependent on the seawall and elevated roadway, measures A through H, would be implemented to abut the seawall and elevated roadway and would be constructed to a maximum elevation of 1.0 foot lower than the seawall and elevated roadway, or to elevation 10.0 feet NAVD88, thus acting as a system. For these measures, equivalent annual damage reduction would be limited to structures that are physically located south of Beach Boulevard, since seawall and elevation of that roadway would be higher than the dune system itself. A visual description of this system can be seen above in figure 6.3-3. The remaining measures I, J, and K are stand alone, and would be implemented in lieu of the seawall and elevated roadway with dune system. The equivalent annual damage reduction attributable to the stand alone measures would impact structures located south of Beach Boulevard in planning unit one and some footprint of structures north of beach boulevard. Also, all beach and dune placement measures would provide some level of protection to the seawall and roadways that they abut, but those benefits are difficult to quantify and were not conducted in this analysis.

The Beach-FX program was selected to quantify the damage reduction benefits of all of the beach and dune placement measures. Beach-FX is a Monte Carlo based model that combines coastal processes economic conditions to evaluate damages from storm events and the level of damage reduction that would be attributable to a given measure. Chapter III of this appendix depicts the overall process of the Beach-FX evaluation. For this study, the exploration of the costal processes and economic inventorying was conducted. Further study would be required to combine the observed data and to evaluate the eleven alternatives previously mentioned. More detail on the further study can be found in the MsCIP Comprehensive Plan Main Report. Table 6.3-1 summarizes the costs by measure.

Summary of Costs

Table 6.3-1 summarizes the ROM costs at an FY-08 price level for the beach and dune placement measures for planning unit one.

Table 6.3-1.
Summary of Beach and Dune Costs by Measure for Planning Unit One

Measures	Implementation Cost ($)	IDC ($)	Total Implementation Cost ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A[1] (10FT by 40FT Dune no plantings)	$8,070,000	$178,700	$8,248,700	$443,139	$2,167,694	$2,610,833
Measure B[1] (8FT by 50FT Dune no plantings)	$6,100,000	$134,900	$6,234,900	$334,953	$1,638,530	$1,973,483
Measure C[1] (10FT by 20ft Dune no plantings)	$4,960,000	$109,600	$5,069,600	$272,350	$1,332,313	$1,604,663
Measure D[1] (8FT by 30FT Dune no plantings)	$4,030,000	$89,200	$4,119,200	$221,293	$1,082,504	$1,303,797
Measure E[1] (10FT by 40FT Dune with plantings)	$8,400,000	$185,900	$8,585,900	$461,254	$2,256,336	$2,717,590
Measure F[1] (8FT by 50FT Dune with plantings)	$6,440,000	$142,500	$6,582,500	$353,627	$1,729,857	$2,083,484
Measure G[1] (10FT by 20ft Dune with plantings)	$5,300,000	$117,300	$5,417,300	$291,030	$1,423,640	$1,714,670
Measure H[1] (8FT by 30FT Dune with plantings)	$4,360,000	$96,400	$4,456,400	$239,408	$1,171,146	$1,410,554
Measure I (10FT by 50FT Dune without plantings)	$19,100,000	$422,600	$19,522,600	$1,048,799	$5,130,478	$6,179,277
Measure J (10FT by 50FT Dune with plantings)	$19,450,000	$430,300	$19,880,300	$1,068,015	$5,224,492	$6,292,507
Measure K (2FT by 60FT Dune with plantings)	$4,640,000	$102,600	$4,742,600	$254,783	$0	$254,783

1/ Denotes measures that could not be implemented without the construction of the seawall, which is discussed in section 6.4.
2/ Cost include Construction Management, Supervision & Administration, and Contingencies. More detail on the costs can be found in the Cost Estimating Appendix.

6.3.1.6 National Ecosystem Restoration (NER)

The P&G defines the environmental quality account as, "displays of non-monetary effects on ecological, cultural, and aesthetic resources…" The EQ account is typically associated with ecosystem restoration projects, although it does address the following:

Cost Effective Analysis

The justification for the proposed section is evaluated on a cost effective and incremental cost basis in accordance with guidelines contained in ER 1105-2-100, *Planning – Planning Guidance Notebook*. The Corps' ecosystem restoration policy is described in more detail in ER 1165-2-501, *Water Resources Policies and Authorities – Civil Works Ecosystem Restoration Policy;* and EP 1165-2-501, *Water Resources Policies and Authorities – Ecosystem Restoration – Supporting Policy Information.* As cited in the *Planning Guidance Notebook,* Cost Effectiveness and Incremental Cost Analyses procedures are detailed in IWR Report 94-PS-2, Cost Effectiveness Analysis for Environmental Planning: Nine EASY steps; IWR Report 95-R-1, *Evaluation of Environmental Investments Procedures Manual Interim: Cost Effectiveness and Incremental Cost Analyses; and IWR Report 98-R-1, Making More Informed Decisions in Your Watershed When Dollars aren't Enough*. The analysis compares the cost effectiveness of the five measures based on their environmental outputs to determine the selected measure. Note: this section is intended to identify the cost effective environmental measures that can be constructed with the elevated roadway and seawall. Since measures I, J, and K are concept measures at the time of this report, and they were formulated based on reducing flood damages to be stand alone measures, they will automatically be carried forward for further consideration.

6.3.1.6.1 Cost Effective Analysis Assumptions

This analysis assumes a 50-year project life. Costs were amortized using the FY 2008 federal discount rate of 4.875-percent and are presented at October 2008 price levels. The outputs quantified in this cost effective analysis are defined as the quantification of expected improvements in target functions as related to project objectives (functional habitat index, FHI). FHI scores were based on an assessment protocol, which provide a basic level of stream health evaluation that is based on physical conditions within the assessment area. The assessment is used to record the scores for up to 15 assessment elements (i.e., channel condition, hydrologic alteration, riparian zone, bank stability, water appearance, nutrient enrichment, barriers to fish movement, instream fish cover, pools, insect/invertebrate habitat, canopy cover [warm water fishery], manure presence, salinity, riffle embeddedness, and macroinvertebrates observed). However, all assessment elements were not applicable to the assessment area and were not included.

The first step in cost-effective analysis is to display the environmental outputs (effects on habitat expressed in Functional Habitat Index, FHI) and the cost estimates of the management measure increments. Outputs and costs are displayed as average annual outputs and average annual costs. Both are acceptable so long as they are comparable. Average annual outputs and average annual costs were used for this analysis.

Table 6.3-2 displays the project measures and their associated average annual outputs and average annual costs. Project outputs for each measure are displayed in terms of functional habitat index (FHI) that can be supported for each measure considered.

Table 6.3-2.
Outputs and Costs by Measure

Measures	Annualized Implementation Cost ($)	Annual O&M ($)	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	$0	$0	0
Measure A	$443,139	$2,167,694	$2,610,833	142
Measure B	$334,953	$1,638,530	$1,973,483	172
Measure C	$272,350	$1,332,313	$1,604,663	142
Measure D	$221,293	$1,082,504	$1,303,797	154
Measure E	$461,254	$2,256,336	$2,717,590	304
Measure F	$353,627	$1,729,857	$2,083,484	330
Measure G	$291,030	$1,423,640	$1,714,670	250
Measure H	$239,408	$1,171,146	$1,410,554	276

The second step in incremental analysis is to identify combinable management measures. This involves the analysis of the management measures to determine those that can be implemented together from those that cannot be implemented together. Each of the measures in this analysis is independent of the others. After the selection of one of the measures, the other measures are not needed; therefore the measures are not combinable.

The next step is to calculate outputs and costs of combinations. The combinations of the management measures are defined and analyzed incrementally. In this step, each combination of output (FHI) and cost ($) is calculated. However, since the measures cannot be combined, this step is not necessary in this case.

Eliminating economically inefficient solutions is the fourth step in incremental analysis. In order to do this, the list of solutions is reordered so that they are listed in ascending order of their outputs. Where two or more solutions produce the same output, the solutions are ranked in ascending order of their costs. The result is a ranking of measures AA, A, C, D, B, G, H, E, and F as displayed below in table 6.3-3. At each level of output the least cost measure is determined. Measure A was identified as an inefficient measure because it provides the same output as measure C for a greater cost. Measure A will not be carried forward in this analysis.

Table 6.3-3.
List of Efficient Measures

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure A	$2,610,833	142
Measure C	$1,604,663	142
Measure D	$1,303,797	154
Measure B	$1,973,483	172
Measure G	$1,714,670	250
Measure H	$1,410,554	276
Measure E	$2,717,590	304
Measure F	$2,083,484	330

The fifth step in incremental analysis is to eliminate economically ineffective solutions. The outputs and costs undergo a pair-wise comparison. The results of the comparison are analyzed to determine which solutions will produce less output at equal or greater cost than subsequently ranked solutions. Those solutions that will produce less output at equal or greater cost than subsequently ranked solutions are deleted. Measures C, B, G, and E were eliminated because they were found to be ineffective solutions. Measure C was eliminated because measure D produces more output for less cost than measure C, measures B and G were eliminated because measure H produces more output for less cost, and measure E was eliminated because measure F produces more output for less cost. Table 6.3-4 summarizes the results of step five.

Table 6.3-4.
List of Effective Measures

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure C	$1,604,663	142
Measure D	$1,303,797	154
Measure B	$1,973,483	172
Measure G	$1,714,670	250
Measure H	$1,410,554	276
Measure E	$2,717,590	304
Measure F	$2,083,484	330

Step six calculates the average cost of each of the cost effective solutions and eliminates those measures that yield less output at a higher cost than the measure with the lowest average cost per functional habitat index (FHI). Step seven repeats step six to further screen measures. Steps eight and nine perform an incremental cost analysis on the measures that were moved forward after going through steps six and seven.

Traditionally, these steps are part of the incremental analysis portion of the “Nine Easy Steps” and are performed on the remaining measures. However, since the Congressional Authority that was given to do the MsCIP Comprehensive study specifically directs the Corps of Engineers not to conduct Incremental Cost Analysis, this analysis will conclude at step six, with measures D, H and F moving forward for further consideration. Table 6.3-5 shows the environmentally cost effective measures for beach and dune placement for planning unit one that will be carried forward for further comparison.

Table 6.3-5.
List of Cost Effective Measures for Planning Unit One

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure D	$1,303,797	154
Measure H	$1,410,554	276
Measure F	$2,083,484	330
Measure I	$6,179,277	136
Measure J	$6,292,507	216
Measure K	$254,783	248

6.3.1.7 Regional Economic Development (RED)

The purpose of this section is to show the regional economic impact of the cost effective measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Hancock County, Mississippi. The expenditures for the measures are estimated to be $4,030,000 for the Measure D measure, $6,440,000 for the Measure F measure, $4,360,000 for the Measure H measure, $19,100,000 for the Measure I measure, $19,450,000 for the Measure J measure and $4,640,000 for the Measure K measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $20,150,000 for the measure D, $32,200,000 for the measure F, $21,800,000 for the measure H, $95,500,000 for the measure I, $97,520,000 for the Measure J measure and $0 for the Measure K measure (assuming a 50-year period of analysis and an interest rate of 4.875 percent). Tables 6.3-6 through 6.3-9 summarize the EIFS model inputs and outputs for the beach and dune placement measures at for Planning Unit One.

Table 6.3-6.
EIFS Model Implementation Inputs for LOD2

	Measure D	Measure F	Measure H	Measure I	Measure J	Measure K
Region of Influence (ROI)	Hancock County	Hancock County	Hancock County	Hancock County	Hancock County	Hancock County
Change in Local Expenditures	$4,030,000	$6,440,000	$4,360,000	$19,100,000	$19,450,000	$4,640,000

Based of the given inputs the outputs are as follows:

Table 6.3-7.
EIFS Model Implementation Outputs for LOD2

	Measure D	Measure F	Measure H	Measure I	Measure J	Measure K
Direct Sales Volume	$4,030,000	$6,440,000	$4,360,000	$19,100,000	$19,450,000	$4,640,000
Induced Sales Volume	$4,030,000	$6,440,000	$4,360,000	$19,100,000	$19,450,000	$4,640,000
Total Sales Volume	$8,060,000	$12,880,000	$8,720,000	$38,200,000	$38,900,000	$9,280,000
Direct Income	$971,774	$1,552,910	$1,051,349	$4,605,680	$4,690,077	$1,118,867
Induced Income	$971,774	$1,552,910	$1,051,349	$4,605,680	$4,690,077	$1,118,867
Total Income	$1,943,549	$3,105,820	$2,102,698	$9,211,359	$9,380,154	$2,237,733
Direct Employment	24	39	26	116	118	28

6.3.1.8 Summary of Cost Effective Measures and their Benefits

Table 6.3-10 shows the potential measures that are being carried forward for further consideration. Measures D, H, and F are beach and dune placement measures that depend on the construction of the seawall in order to be implemented. Measures I, J, and K are stand alone measures that do not depend on the seawall and elevated roadway for implementation.

Table 6.3-10.
List of Cost Effective Measures Carried Forward for Further Consideration
Planning Unit One

Measures	Total Annual Cost ($)	Environmental Output (FHI)	Change in Sales Volume	Change in Income	Change in Employment
Measure AA (No Action)	$0	0	$0	$0	0
Measure D	$1,303,797	154	$48,360,000	$11,661,292	293
Measure H	$1,410,554	276	$52,320,000	$12,616,186	317
Measure F	$2,083,484	330	$77,280,000	$18,634,917	468
Measure I	$6,179,277	136	$229,200,000	$55,268,156	1,387
Measure J	$6,292,507	216	$233,400,000	$56,280,923	1,412
Measure K	$254,783	248	$9,280,000	$2,237,733	56

6.3.1.9 Public Access and Parking

An analysis of public access and parking was conducted on the sections where beach and dune construction would take place. It was determined that planning unit one has sufficient access and parking to satisfy the requirements established in Engineering Regulation (ER) 1165-2-100. Planning unit one has access along the entire stretch of beach with 592 parking spaces that are available to everyone for no cost. Addendum C describes the result of the access and parking analysis in greater detail.

6.3.2 Panning Unit Two

6.3.2.1 Background

The beaches of Hancock County are approximately 9 miles in length, and host one of the Gulf Coast's largest populations of Least Tern, a Federally-listed endangered species, plus a significant number of Piping Plover. The beaches possessed a dune system (pre-Katrina) that was maintained by local interests, that was vegetated and supported a significant ecosystem, in addition to passive recreation usage outside the dune system. This dune system provided not only ecosystem benefits, but some measure of hurricane or storm damage reduction due to its ability to absorb some of the surge and wave energy during those types of events. During Hurricane Katrina, this dune system was almost entirely destroyed by surge and wave action. Almost all ecosystem functions and values were eliminated during this single event. Much of the sand removed is believed to be close off shore in the near shore zone. The MsCIP Interim Chief's Report recommended that a beach and dune placement project be constructed in Panning Unit 3. This interim project consists of restoring approximately 26 miles of dune systems that were destroyed by Hurricane Katrina. The proposed project area for planning unit two is shown in figures 6.3.2-1 through 6.3.2-3.

6.3.2.1.1 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation
- Prevention or remediation of Saltwater Intrusion
- Preservation of Fish & Wildlife and restoration of their habitats
- Prevention or remediation of erosion
- Other related water resource purposes, such as ecosystem restoration or barrier island restoration

Figure 6.3.2-1. Project Sites for LOD2 in Panning Unit 2

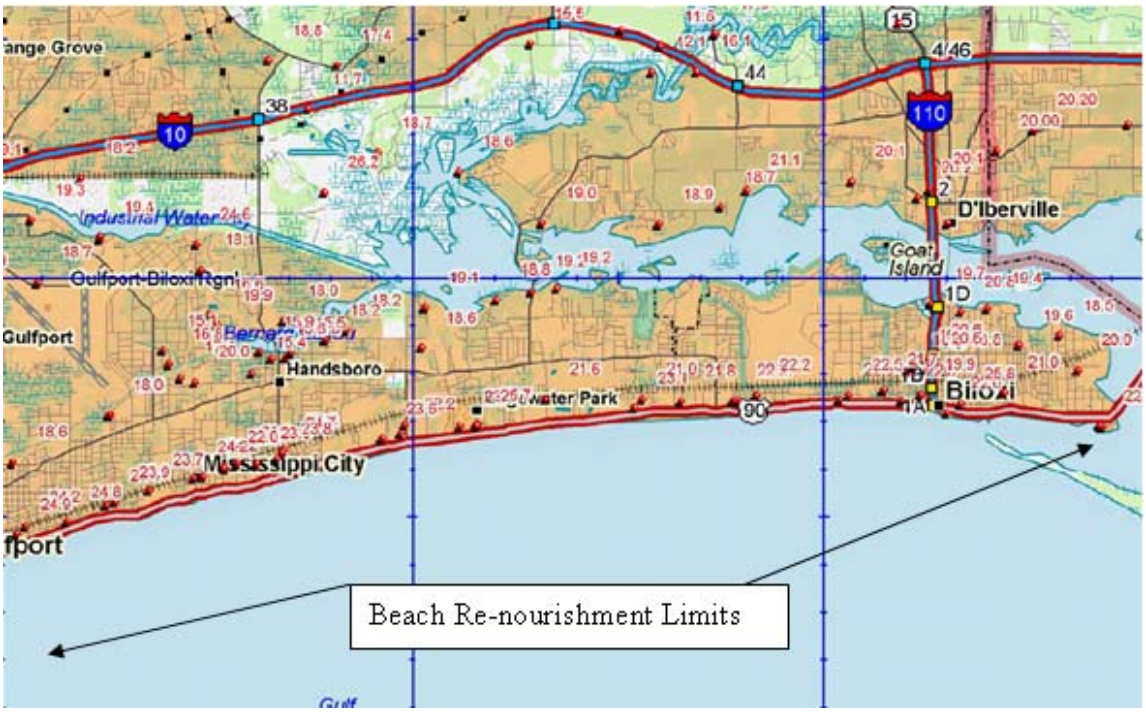

Figure 6.3.2-2. Eastern Project Limits for Line of Defense 2 in Panning Unit 2

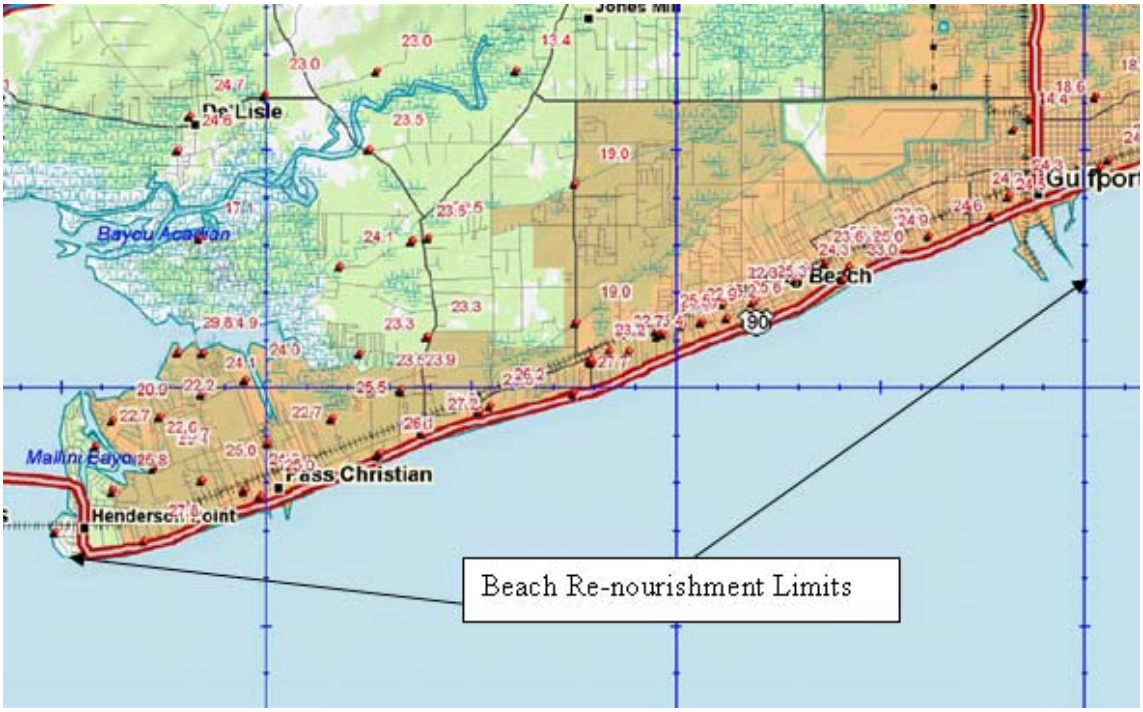

Figure 6.3.2-3. Western Project Limits for Line of Defense 2 in Panning Unit 2

6.3.2.2 General Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 50-year period of analysis was used to calculate average annual benefits and costs.

6.3.2.3 Measures

Eleven plans were evaluated for enhanced beach protection at the study site. All involve providing a dune and berm to the location. Some of the alternatives, Measures A through H described below, can not be constructed without the construction of the Seawall and Elevated roadway measure, which is evaluated in great detail later in this appendix. The measures for Line of Defense 2 in Panning Unit 2 are as follows:

- Measure A consists of a 15.0 feet NAVD88 dune elevation, 35.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure B consists of a 13.0 feet NAVD88 dune elevation, 45.0 feet NAVD88 dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure C consists of a 15.0 feet NAVD88 dune elevation, 25.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 170.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure D consists of a 13.0 feet NAVD88 dune elevation, 15.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure E consists of a 15.0 feet NAVD88 dune elevation, 35.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure F consists of a 13.0 feet NAVD88 dune elevation, 45.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure G consists of a 15.0 feet NAVD88 dune elevation, 25.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 170.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure H consists of a 13.0 feet NAVD88 dune elevation, 15.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 160.0 feet width, an upper berm elevation of 7.2 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern,

with a total of three rows of plants starting at the seaward toe of the dune. Figure 6.3.2-4 shows a typical cross section for Measures A though H.

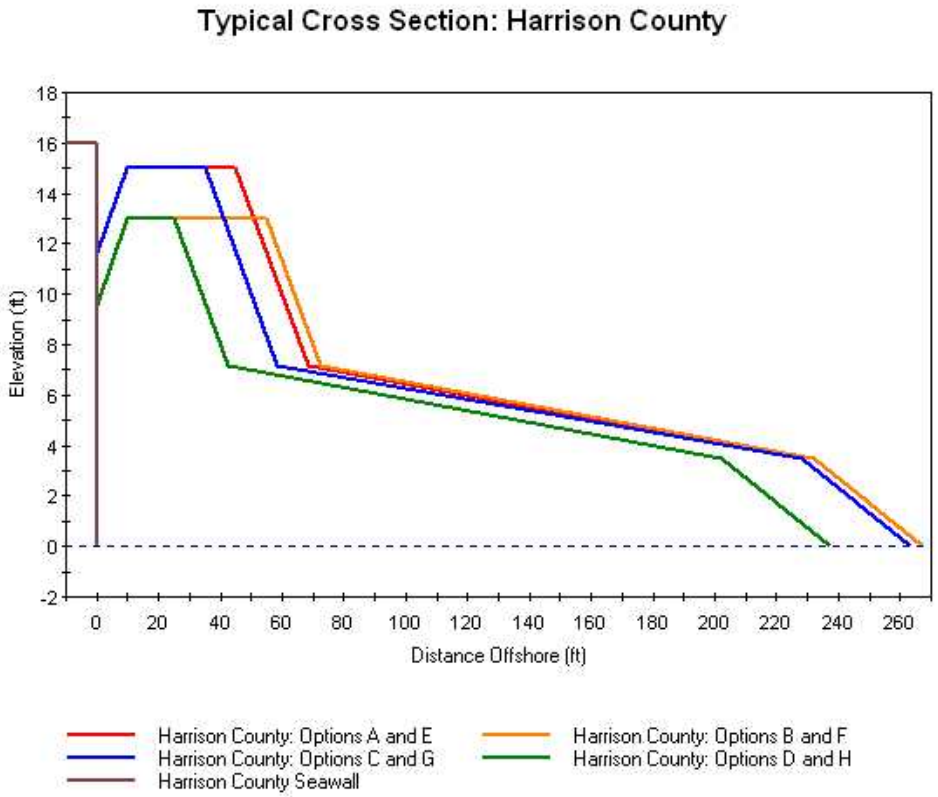

Figure 6.3.2-4. Typical Cross Section for Measures A through H

- Measures I and J are comparative with-project measures, for future evaluation, consisting of a design cross-section which includes a dune and berm constructed as a stand alone project which does not incorporate the Line of Defense 3 seawall. Measure I consists of a dune feature constructed approximately 50.0 feet seaward of the seawall at an elevation of 15.0 feet NAVD 88, with a crest width of 55.0 feet, and a dune slope of 1:3. The berm width would be extended to accommodate the placement of the dune feature. Sand fencing would be placed on the dunes to reduce sand transport due to the strong winds which frequently occur during storms. The cross section for Measure J is the same as Measure I; however the dune would be planted to provide for additional environmental habitat. For Measure J, sea oats would be planted on both the landward and seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the landward and seaward toes of the dune. The dunes will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Measures I and J is shown in Figure 6.3.2-5.

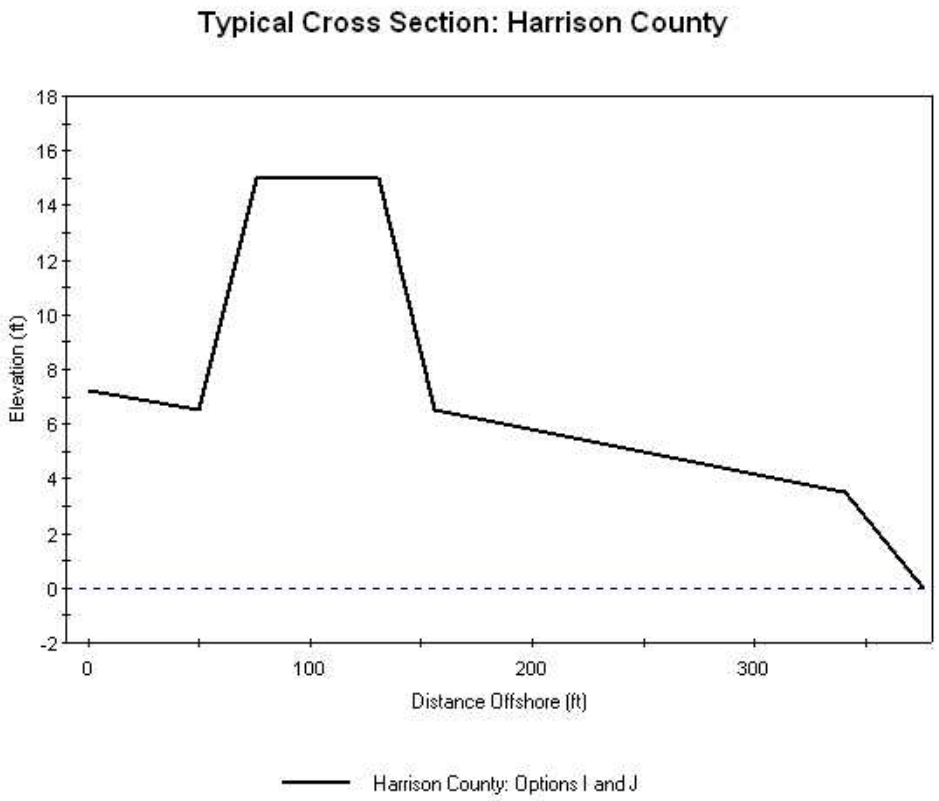

Figure 6.3.2-5. Typical Cross Section for Measures I and J

- Measure K is also a measure for future evaluation which consists of an elevated berm section constructed primarily for the creation of environmental habitat. Measure K would be constructed as a stand alone measure which does not incorporate the Line of Defense 3 seawall. The elevated berm section would be constructed approximately 50.0 feet seaward of the existing seawall to an elevation 2.0 feet above the existing berm with a width of approximately 60.0 feet. The berm width would not be extended to accommodate the placement of the elevated berm feature. The new feature would be vegetated and sand fencing would be placed to create environmental habitat and to reduce sand transport due to the strong winds which frequently occur during storms. For Measure K, sea oats would be planted in a 30 by 30 inch grid pattern over the entire elevated berm area. The new feature will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Measure K is shown in Figure 6.3.2-6.

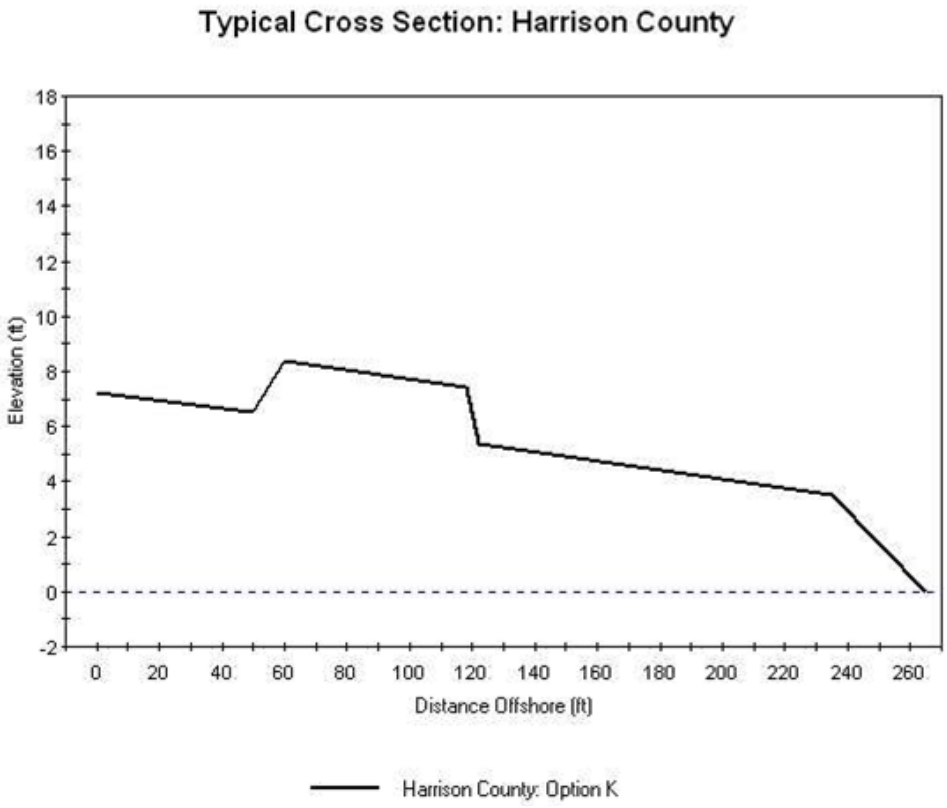

Figure 6.3.2-6. Typical Cross Section for Measure K

6.3.2.4 National Economic Development (NED)

This section describes the National Economic Development benefits for the various beach and dune placement measures in planning unit two that are attributable to hurricane and storm damage reduction. National economic development benefits are damages to structures and their contents that are reduced when a measure or alternative is implemented, or the difference between the with-project and without-project conditions.

There are two types of beach and dune placement measures for planning unit two; those that are dependent on the seawall and elevated roadway and those that can be implemented as stand alone measures. Those measures dependent on the seawall and elevated roadway, measures A through H, would be implemented to abut the seawall and elevated roadway and would be constructed to a maximum elevation of 1.0 foot lower than the seawall and elevated roadway, or to elevation 15.0 feet NAVD88, thus acting as a system. For these measures, equivalent annual damage reduction would be limited to structures that are physically located south of Beach Boulevard, since seawall and elevation of that roadway would be higher than the dune system itself. A visual description of this system can be seen above in figure 6.3-7. The remaining measures I, J, and K are stand alone, and would be implemented in lieu of the seawall and elevated roadway with dune system. The equivalent annual damage reduction attributable to the stand alone measures would impact structures located south of Beach Boulevard in planning unit two and some footprint of structures north of beach boulevard. Also, all beach and dune placement measures would provide some level of protection to the seawall and roadways that they abut, but those benefits are difficult to quantify and were not conducted in this analysis.

The Beach-FX program was selected to quantify the damage reduction benefits of all of the beach and dune placement measures. Beach-FX is a Monte Carlo based model that combines coastal processes economic conditions to evaluate damages from storm events and the level of damage reduction that would be attributable to a given measure. Chapter III of this appendix depicts the overall process of the Beach-FX evaluation. For this study, the exploration of the costal processes and economic inventorying was conducted. Further study would be required to combine the observed data and to evaluate the eleven alternatives previously mentioned. More detail on further study can be found in the MsCIP Comprehensive Plan Main Report. Table 6.3.2-1 summarizes the costs by measure for planning unit two.

6.3.2.6 National Ecosystem Restoration (NER)

The P&G defines the environmental quality account as, "displays of non-monetary effects on ecological, cultural, and aesthetic resources…" The EQ account is typically associated with ecosystem restoration projects, although it does address the following:

6.3.2.6.1 Cost Effective Analysis Assumptions

This analysis assumes a 50-year project life. Costs were amortized using the FY 2008 federal discount rate of 4.875-percent and are presented in October 2007 dollars. The outputs quantified in this cost effective analysis are defined as the quantification of expected improvements in target functions as related to project objectives (functional habitat index, FHI). FHI scores were based on an assessment protocol, which provide a basic level of stream health evaluation that is based on physical conditions within the assessment area. The assessment is used to record the scores for up to 15 assessment elements (i.e., channel condition, hydrologic alteration, riparian zone, bank stability, water appearance, nutrient enrichment, barriers to fish movement, instream fish cover, pools, insect/invertebrate habitat, canopy cover [warm water fishery], manure presence, salinity, riffle embeddedness, and macroinvertebrates observed). However, all assessment elements were not applicable to the assessment area and were not included.

The first step in cost-effective analysis is to display the environmental outputs (effects on habitat expressed in Functional Habitat Index, FHI) and the cost estimates of the management measure increments. Outputs and costs can be displayed as average annual outputs and average annual costs or total outputs and total costs. Both are acceptable so long as they are comparable. Average annual outputs and average annual costs were used for this analysis.

Table 6.3.2-2 displays the project alternatives and their associated average annual outputs and average annual costs. Project outputs for each alternative are displayed in terms of functional habitat index (FHI) that can be supported for each alternative considered.

Summary of Costs

Table 6.3.2-1 summarizes the ROM costs at an FY-08 price level for the beach and dune measures in planning unit two.

Table 6.3.2-1.
Summary of Beach and Dune Costs by Measure for Planning Unit Two

Measures	Implementation Cost (FY-08) ($)	IDC ($)	Total Implementation Cost ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A[1] (15FT by 35FT Dune without plantings)	$21,840,000	$752,800	$22,592,800	$1,213,737	$5,866,473	$7,080,210
Measure B[1] (13FT by 45FT Dune without plantings)	$18,600,000	$641,200	$19,241,200	$1,033,681	$4,996,172	$6,029,853
Measure C[1] (15FT by 25FT Dune without plantings)	$18,100,000	$624,100	$18,724,100	$1,005,901	$4,861,867	$5,867,768
Measure D[1] (13FT by 15FT Dune without plantings)	$10,400,000	$358,500	$10,758,500	$577,971	$2,793,559	$3,371,530
Measure E[1] (15FT by 35FT Dune with plantings)	$22,970,000	$791,800	$23,761,800	$1,276,538	$6,170,004	$7,446,542
Measure F[1] (13FT by 45FT Dune with plantings)	$19,760,000	$681,200	$20,441,200	$1,098,148	$5,307,761	$6,405,909
Measure G[1] (15FT by 25FT Dune with plantings)	$19,210,000	$662,100	$19,872,100	$1,067,575	$5,160,025	$6,227,600
Measure H[1] (13FT by 15FT Dune with plantings)	$11,520,000	$397,100	$11,917,100	$640,214	$3,094,403	$3,734,617
Measure I (Standalone 15FT Dune without plantings)	$40,290,000	$1,389,000	$41,679,000	$2,239,091	$10,822,354	$13,061,445
Measure J (Standalone 15FT Dune with plantings)	$41,460,000	$1,429,000	$42,889,000	$2,304,095	$11,136,629	$13,440,724
Measure K (Standalone 2FT Dune with plantings)	$9,680,000	$333,600	$10,013,600	$537,953	$0	$537,953

1/ Denotes measures that could not be implemented without the construction of the seawall, which is discussed in section 6.4.
2/ Cost include Construction Management, Supervision & Administration, and Contingencies. More detail on the costs can be found in the Cost Estimating Appendix.

Table 6.3.2-2.
Outputs and Costs by Measure

Measures	Annualized Implementation Cost ($)	Annual O&M ($)	Total Annual Cost ($)	Output (FHI)
Measure AA (No Action)	$0	$0	$0	0
Measure A	$1,213,737	$5,866,473	$7,080,210	142
Measure B	$1,033,681	$4,996,172	$6,029,853	172
Measure C	$1,005,901	$4,861,867	$5,867,768	154
Measure D	$577,971	$2,793,559	$3,371,530	130
Measure E	$1,276,538	$6,170,004	$7,446,542	304
Measure F	$1,098,148	$5,307,761	$6,405,909	330
Measure G	$1,067,575	$5,160,025	$6,227,600	276
Measure H	$640,214	$3,094,403	$3,734,617	250

The second step in cost effective analysis is to identify combinable management measures. This involves the analysis of the management measures to determine those that can be implemented together from those that cannot be implemented together. Each of the alternatives in this analysis is independent of the others. After the selection of one of the alternatives, the other alternatives are not needed; therefore the alternatives are not combinable.

The next step is to calculate outputs and costs of combinations. The combinations of the management measures are defined and analyzed incrementally. In this step, each combination of output (HU) and cost ($) is calculated. However, since the alternatives cannot be combined, this step is not necessary in this case.

Eliminating economically inefficient measures is the fourth step in cost effective analysis. In order to do this, the list of measures is reordered so that they are listed in ascending order of their outputs. Where two or more measures produce the same output, the measures are ranked in ascending order of their costs. The result is a ranking of measures AA, D, A, C, B, H, G, E, and F as displayed below in table 6.3.2-3. At each level of output the least cost measure is determined. No measures were identified as inefficient measures since all of the measures provide different levels of environmental lift; therefore all measures will be carried forward to the next step of this analysis.

Table 6.3.2-3.
List of Efficient Measures

Measures	Total Annual Cost ($)	Output (FHI)
Measure AA (No Action)	$0	0
Measure D	$3,371,530	130
Measure A	$7,080,210	142
Measure C	$5,867,768	154
Measure B	$6,029,853	172
Measure H	$3,734,617	250
Measure G	$6,227,600	276
Measure E	$7,446,542	304
Measure F	$6,405,909	330

The fifth step in cost effective analysis is to eliminate economically ineffective measures. The outputs and costs undergo a pair-wise comparison. The results of the comparison are analyzed to determine which measures will produce less output at equal or greater cost than subsequently ranked measures. Those measures that will produce less output at equal or greater cost than subsequently ranked measures are deleted. Measures A, C, and B were eliminated because they were found to be ineffective measures. Measure H produces more output for less cost than measures A, C, B. The results of this step are shown in table 6.3.2-4.

Table 6.3.2-4.
List of Effective Measures

Measures	Total Annual Cost ($)	Output (FHI)
Measure AA (No Action)	$0	0
Measure D	$3,371,530	130
Measure A	$7,080,210	142
Measure C	$5,867,768	154
Measure B	$6,029,853	172
Measure H	$3,734,617	250
Measure G	$6,227,600	276
Measure E	$7,446,542	304
Measure F	$6,405,909	330

Step six calculates the average cost of each of the cost effective measures and eliminates those measures that yield less output at a higher cost than the measure with the lowest average cost per functional habitat index (FHI). Step seven repeats step six to further screen alternatives. Steps eight and nine perform an incremental cost analysis on the measures that were moved forward after going through steps six and seven.

Traditionally, these steps are part of the cost effective analysis portion of the “Nine Easy Steps” and are performed on the remaining plans. However, since the Congressional Authority that was given to do the MsCIP Comprehensive study specifically directs the Corps of Engineers not to conduct Incremental Cost Analysis, this analysis will conclude at step five, with measures D, G, H and F moving forward for further consideration. Table 6.3.2-5 shows the environmentally cost effective plans for beach and dune placement for Panning Unit two that will be carried forward for further comparison.

Table 6.3.2-5.
List of Cost Effective Measures for Planning Unit Two

Measures	Total Annual Cost ($)	Output (FHI)
Measure AA (No Action)	$0	0
Measure D	$3,371,530	130
Measure H	$3,734,617	250
Measure G	$6,227,600	276
Measure F	$6,405,909	330
Measure I	$13,061,445	140
Measure J	$13,440,724	220
Measure K	$537,953	240

6.3.2.7 Regional Economic Development (RED)

The purpose of this section is to show the economic impact of the cost effective measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Harrison County, Mississippi. The expenditures for the measures are estimated to be $10,400,000 for the measure D, $19,760,000 for the measure F, $19,210,000 for measure G, $11,520,000 for the measure H, $40,290,000 for the measure I, $41,460,000 for the measure J, and $9,680,000 for the measure K. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $52,000,000 for the measure D, $98,800,000 for the measure F, $$96,050,000 for measure G, $57,600,000 for the measure H, $201,450,000 for the measure I, $207,300,000 for the measure J, and $0 for the measure K (assuming a 50-year period of analysis and an interest rate of 4.875 percent). Tables 6.3.2-6 through 6.3.2-9 summarize the EIFS model inputs and outputs for the beach and dune placement measures at Planning Unit Two.

Table 6.3.2-6.
EIFS Model Implementation Cost Inputs for LOD2

	Measure D	Measure F	Measure G	Measure H	Measure I	Measure J	Measure
Region of Influence (ROI)	Harrison County	Harrison County	Harrison County	Harrison County	Harrison County	Harrison County	Harrison County
Change in Local Expenditures	$10,400,000	$19,760,000	$19,210,000	$11,520,000	$40,290,000	$41,460,000	$9,680,000

Based of the given inputs the outputs are as follows:

Table 6.3.2-7.
EIFS Model Implementation Cost Outputs for LOD2

	Measure D	Measure F	Measure G	Measure H	Measure I	Measure J	Measure K
Direct Sales Volume	$10,400,000	$19,760,000	$19,210,000	$11,520,000	$40,290,000	$41,460,000	$9,680,000
Induced Sales Volume	$13,000,000	$24,700,000	$24,012,500	$14,400,000	$50,362,500	$51,825,000	$12,100,000
Total Sales Volume	$23,400,000	$44,460,000	$43,222,500	$25,920,000	$90,652,500	$93,285,000	$21,780,000

6.3.2.8 Summary of Cost Effective Measures

Table 6.3.2-10 shows the potential measures that are being carried forward for further consideration. Measures D, H, G, and F are beach and dune placement measures that depend on the construction of the seawall in order to be implemented. Measures I, J, and K are stand alone measures that do not depend on the seawall for implementation.

Table 6.3.2-10.
List of Measures Carried Forward for Further Evaluation in Planning Unit Two
Planning Unit Two

Measures	Total Annual Cost ($)	Total Annual Output (FHI)	Change in Sales Volume	Change in Income	Change in Employment
Measure AA (No Action)	$0	0	$0	$0	0
Measure D[1]	$3,371,530	130	$140,400,000	$29,719,219	892
Measure H[1]	$3,734,617	250	$155,520,000	$32,919,750	988
Measure G[1]	$6,227,600	276	$259,335,000	$54,894,826	1,647
Measure F[1]	$6,405,909	330	$266,760,000	$56,466,515	1,694
Measure I	$13,061,445	140	$543,915,000	$115,133,396	3,454
Measure J	$13,440,724	220	$559,710,000	$118,476,808	3,555
Measure K	$537,953	240	$21,780,000	$4,610,289	138

6.3.2.9 Public Access and Parking

A parking and access analysis was conducted on the sections where beach and dune constriction would take place for planning unit two. It was determined that planning unit two has sufficient access and parking to satisfy the requirements established in Engineering Regulation (ER) 1165-2-100. Planning unit two also has access along the entire twenty-six mile length of beach and has 2,788 free parking spaces. Addendum C describes the result of the access and parking analysis in greater detail.

6.3.3 Planning Unit Three

6.3.3.1 Background

The beaches of Jackson County are host one of the Gulf Coast's largest populations of Least Tern, a Federally-listed endangered species, plus a significant number of Piping Plover. During Hurricane Katrina, this dune system was almost entirely destroyed by surge and wave action. Almost all ecosystem functions and values were eliminated during this single event. Much of the sand removed is believed to be close off shore in the near shore zone. The MsCIP Interim Chiefs Report did not recommend a beach and dune placement project be constructed in planning unit three; therefore the without-project condition for this planning unit is the post storm condition. Maintenance occurs on the Jackson County beaches if it is determined that significant erosion occurs following a significant event; with the beaches restored to the pre-storm condition. There is no scheduled periodic maintenance of the beaches. The future without-project conditions assume continuation of the present maintenance activities to restore the berm only feature in Jackson. The berm elevation varies from approximately 5.0 feet NAVD88 at the seawall to 3.5 feet NAVD88 at the slope break to the Mississippi Sound. Figure 6.3.3-1 shows the project location for planning unit three.

Figure 6.3.3-1. Project Sites for Beach and Dune Placement in Planning Unit Three

6.3.3.1.1 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation
- Preservation of Fish & Wildlife and restoration of their habitats
- Prevention or remediation of erosion
- Other related water resource purposes, such as ecosystem restoration or barrier island restoration

6.3.3.2 General Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 50-year period of analysis was used to calculate average annual benefits and costs.

6.3.3.3 Measures

Two plans were evaluated for enhanced beach protection at the study site. All involve providing a dune and berm to the location. Some of the alternatives, Measures A through H described below, can not be constructed without the construction of the Seawall and Elevated roadway measure, which is evaluated in great detail later in this appendix. The measures for Line of Defense 2 in planning unit three are as follows:

- Measure A consists of a 10.0 feet NAVD88 dune elevation, 40.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure B consists of an 8.0 feet NAVD88 dune elevation, 50.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure C consists of a 10.0 feet NAVD88 dune elevation, 20.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure D consists of an 8.0 feet NAVD88 dune elevation, 30.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10.
- Measure E consists of a 10.0 feet NAVD88 dune elevation, 40.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure F consists of an 8.0 feet NAVD88 dune elevation, 50.0 feet dune crest width, with a dune slope of 1:3, and a berm with an 80.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure G consists of a 10.0 feet NAVD88 dune elevation, 20.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.
- Measure H consists of an 8.0 feet NAVD88 dune elevation, 30.0 feet dune crest width, with a dune slope of 1:3, and a berm with a 100.0 feet width, an upper berm elevation of 5.5 feet NAVD88, and seaward berm elevation of 3.5 feet NAVD88, and a foreshore slope of 1:10. In addition, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern,

with a total of three rows of plants starting at the seaward toe of the dune. Figure 6.3.3-2 shows a typical cross section for Measures A though H.

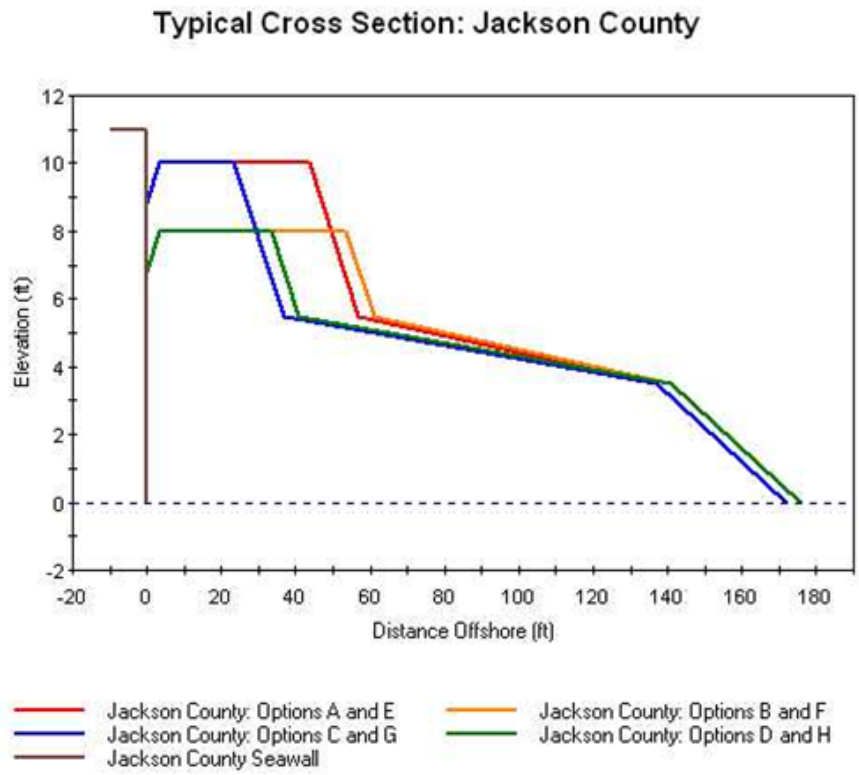

Figure 6.3.3-2. Typical Cross Section for Measures A through H

Measures I and J are comparative with-project measures, for future evaluation, consisting of a design cross-section which includes a dune and berm constructed as a stand alone project which does not incorporate the Line of Defense 3 seawall. Measure I consists of a dune feature constructed approximately 50.0 feet seaward of the seawall at an elevation of 10.0 feet NAVD 88, with a crest width of 55.0 feet, and a dune slope of 1:3. The berm width would be extended to accommodate the placement of the dune feature. Sand fencing would be placed on the dunes to reduce sand transport due to the strong winds which frequently occur during storms. The cross section for Measure J is the same as Measure I; however the dune would be planted to provide for additional environmental habitat. For Measure J, sea oats would be planted on both the landward and seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the landward and seaward toes of the dune. The dunes will require initial and continued maintenance of vegetation and sand fencing. Figure 6.3.3-3 shows the typical cross section for measures I and J.

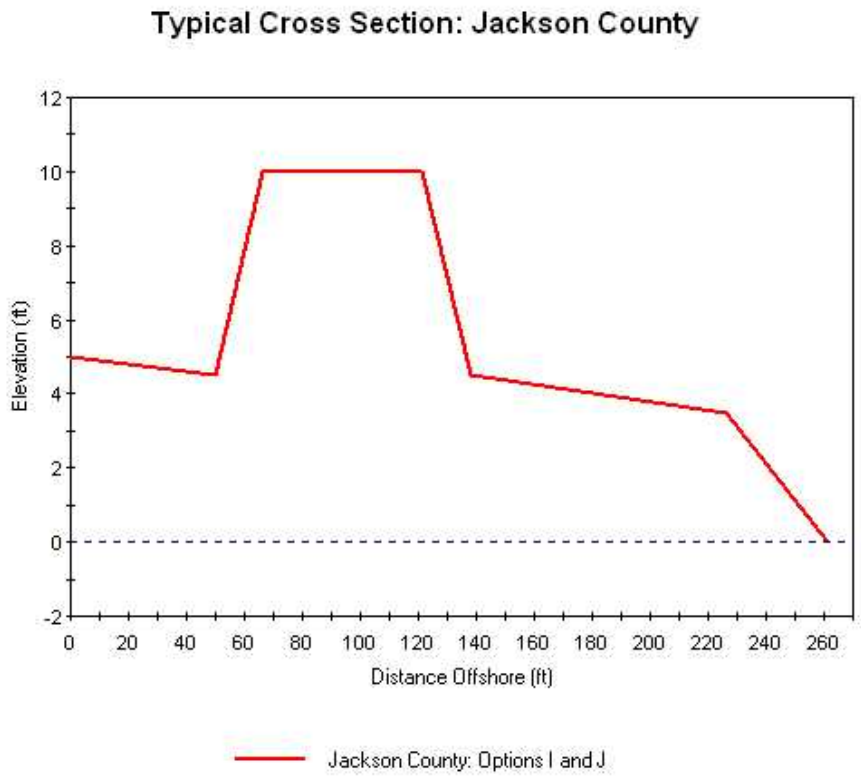

Figure 6.3.3-3. Typical cross section for Measures I and J

Measure K is also a measure for future evaluation which consists of an elevated berm section constructed primarily for the creation of environmental habitat. Measure K would be constructed as a stand alone measure which does not incorporate the Line of Defense 3 seawall. The elevated berm section would be constructed approximately 50.0 feet seaward of the existing seawall to an elevation 2.0 feet above the existing berm with a width of approximately 60.0 feet. The berm width would not be extended to accommodate the placement of the elevated berm feature. The new feature would be vegetated and sand fencing would be placed to create environmental habitat and to reduce sand transport due to the strong winds which frequently occur during storms. For Measure K, sea oats would be planted in a 30 by 30 inch grid pattern over the entire elevated berm area. The new feature will require initial and continued maintenance of vegetation and sand fencing. Figure 6.3.3-4 shows the typical cross section for measure K.

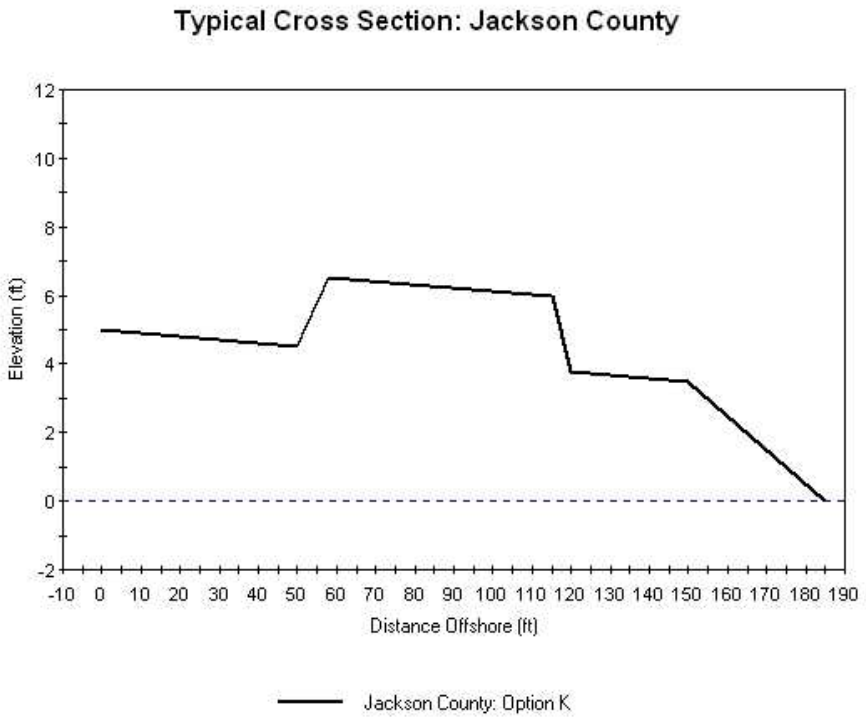

Figure 6.3.3-4. Typical cross section for measure K

6.3.3.4 National Economic Development (NED)

This section describes the National Economic Development benefits for the various beach and dune placement measures in planning unit three that are attributable to hurricane and storm damage reduction. National economic development benefits are damages to structures and their contents that are reduced when a measure or alternative is implemented, or the difference between the with-project and without-project conditions.

There are two types of beach and dune placement measures for planning unit three; those that are dependent on the seawall and elevated roadway and those that can be implemented as stand alone measures. Those measures dependent on the seawall and elevated roadway, measures A through H, would be implemented to abut the seawall and elevated roadway and would be constructed to a maximum elevation of 1.0 foot lower than the seawall and elevated roadway, or to elevation 10.0 feet NAVD88, thus acting as a system. For these measures, equivalent annual damage reduction would be limited to structures that are physically located south of Beach Boulevard, since seawall and elevation of that roadway would be higher than the dune system itself. A visual description of this system can be seen above in figure 6.3-11. The remaining measures I, J, and K are stand alone, and would be implemented in lieu of the seawall and elevated roadway with dune system. The equivalent annual damage reduction attributable to the stand alone measures would impact structures located south of Beach Boulevard in planning unit three and some footprint of structures north of Beach Boulevard. Also, all beach and dune placement measures would provide some level of protection to the seawall and roadways that they abut, but those benefits are difficult to quantify and were not conducted in this analysis.

The Beach-FX program was selected to quantify the damage reduction benefits of all of the beach and dune placement measures. Beach-FX is a Monte Carlo based model that combines coastal processes economic conditions to evaluate damages from storm events and the level of damage reduction that would be attributable to a given measure. Chapter III of this appendix depicts the overall process of the

Beach-FX evaluation. For this study, the exploration of the coastal processes and economic inventorying was conducted. Further study would be required to combine the observed data and to evaluate the eleven alternatives previously mentioned. More detail on the further study can be found in the MsCIP Comprehensive Plan Main Report. Table 6.3.3-1 summarizes the costs for the beach and dune construction measures for planning unit three. For this study, the exploration of the coastal processes and economic inventorying was conducted. Further study would be required to combine the observed data and to evaluate the eleven alternatives previously mentioned. More detail on the further study can be found in the MsCIP Comprehensive Plan Main Report. Table 6.3.3-1 summarizes the costs for the beach and dune construction measures for planning unit three.

6.3.3.5 Summary of Costs

Table 6.3.3-1 summarizes the ROM costs at an FY-08 price level for the beach and dune measures in planning unit three.

Table 6.3.3-1.
Summary of Beach and Dune Costs by Measure for Planning Unit Three

Measures	Implementation Cost ($)	IDC ($)	Total Implementation Cost ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A[1] (10FT by 40FT Dune without plantings)	$1,910,000	$42,200	$1,952,200	$104,877	$513,048	$617,924
Measure B[1] (8FT by 50FT Dune without plantings)	$1,450,000	$32,100	$1,482,100	$79,622	$389,487	$469,108
Measure C[1] (10FT by 20FT Dune without plantings)	$1,180,000	$26,400	$1,206,400	$64,811	$316,961	$381,772
Measure D[1] (8FT by 30FT Dune without plantings)	$960,000	$21,200	$981,200	$52,712	$257,867	$310,579
Measure E[1] (10FT by 40FT Dune with plantings)	$1,990,000	$44,000	$2,034,000	$109,271	$534,537	$643,808
Measure F[1] (8FT by 50FT Dune with plantings)	$1,530,000	$33,900	$1,563,900	$84,016	$410,975	$494,992
Measure G[1] (10FT by 20ft Dune with plantings)	$1,260,000	$27,900	$1,287,900	$69,189	$338,450	$407,639
Measure H[1] (8FT by 30FT Dune with plantings)	$1,040,000	$22,900	$1,062,900	$57,101	$279,356	$336,457
Measure I (10FT by 50FT Dune without plantings)	$4,490,000	$99,400	$4,589,400	$246,553	$1,206,065	$1,452,618
Measure J (10FT by 50FT Dune with plantings)	$4,570,000	$101,200	$4,671,200	$250,948	$1,227,554	$1,478,502
Measure K (2FT by 60FT Dune with plantings)	$1,110,000	$24,600	$1,134,600	$60,953	$0	$60,953

1/ Denotes measures that could not be implemented without the construction of the seawall, which is discussed in section 6.4.
2/ Cost include Construction Management, Supervision & Administration, and Contingencies. More detail on the costs can be found in the Cost Estimating Appendix.

6.3.3.6 National Ecosystem Restoration (NER)

The P&G defines the environmental quality account as, “displays of non-monetary effects on ecological, cultural, and aesthetic resources…” The EQ account is typically associated with ecosystem restoration projects, although it does address the following:

6.3.3.6.1 Cost Effective Analysis Assumptions

This analysis assumes a 50-year project life. Costs were amortized using the FY 2008 federal discount rate of 4.875-percent and are presented in October 2007 dollars. The outputs quantified in this cost effective analysis are defined as the quantification of expected improvements in target functions as related to project objectives (functional habitat index, FHI). FHI scores were based on an assessment protocol, which provide a basic level of stream health evaluation that is based on physical conditions within the assessment area. The assessment is used to record the scores for up to 15 assessment elements (i.e., channel condition, hydrologic alteration, riparian zone, bank stability, water appearance, nutrient enrichment, barriers to fish movement, instream fish cover, pools, insect/invertebrate habitat, canopy cover [warm water fishery], manure presence, salinity, riffle embeddedness, and macroinvertebrates observed). However, all assessment elements were not applicable to the assessment area and were not included.

The first step in cost-effective analysis is to display the environmental outputs (effects on habitat expressed in Functional Habitat Index, FHI) and the cost estimates of the management measure increments. Outputs and costs can be displayed as average annual outputs and average annual costs or total outputs and total costs. Both are acceptable so long as they are comparable. Average annual outputs and average annual costs were used for this analysis.

Table 6.3.3-2 displays the project alternatives and their associated average annual outputs and average annual costs. Project outputs for each alternative are displayed in terms of functional habitat index (FHI) that can be supported for each alternative considered.

Table 6.3.3-2.
Outputs and Costs by Increments by Measure

Measures	Annualized Implementation Cost ($)	Annual O&M ($)	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	$0	$0	0
Measure A	$104,877	$513,048	$617,924	142
Measure B	$79,622	$389,487	$469,108	172
Measure C	$64,811	$316,961	$381,772	142
Measure D	$52,712	$257,867	$310,579	154
Measure E	$109,271	$534,537	$643,808	304
Measure F	$84,016	$410,975	$494,992	330
Measure G	$69,189	$338,450	$407,639	250
Measure H	$57,101	$279,356	$336,457	276

The second step in cost effective analysis is to identify combinable management measures. This involves the analysis of the management measures to determine those that can be implemented together from those that cannot be implemented together. Each of the alternatives in this analysis is independent of the others. After the selection of one of the alternatives, the other alternatives are not needed; therefore the alternatives are not combinable.

The next step is to calculate outputs and costs of combinations. The combinations of the management measures are defined and analyzed incrementally. In this step, each combination of output (FHI) and cost ($) is calculated. However, since the alternatives cannot be combined, this step is not necessary in this case.

Eliminating economically inefficient solutions is the fourth step in cost effective analysis. In order to do this, the list of solutions is reordered so that they are listed in ascending order of their outputs. Where two or more solutions produce the same output, the solutions are ranked in ascending order of their costs. The result is a ranking of measures AA, A, C, D, B, G, H, E, and F as displayed below in table 6.3.3-3. At each level of output the least cost measure is determined. Measure A was identified as an inefficient measure and will not be carried forward in this analysis.

Table 6.3.3-3.
List of Economically Efficient Measures for Planning Unit Three

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure A	$617,924	142
Measure C	$381,772	142
Measure D	$310,579	154
Measure B	$469,108	172
Measure G	$407,639	250
Measure H	$336,457	276
Measure E	$643,808	304
Measure F	$494,992	330

The fifth step in cost effective analysis is to eliminate economically ineffective solutions. The outputs and costs undergo a pair-wise comparison. The results of the comparison are analyzed to determine which solutions will produce less output at equal or greater cost than subsequently ranked solutions. Those solutions that will produce less output at equal or greater cost than subsequently ranked solutions are deleted. Measures C, B, G, and E were eliminated because they were found to be ineffective solutions. These measures were eliminated from further consideration because measure D produces more output for less cost than measure C, measure H produces more output for less cost than measures B and G, and measure F produces more output at less cost than measure E. The results of this step are summarized in table 6.3.3-4.

Step six calculates the average cost of each of the cost effective solutions and eliminates those measures that yield less output at a higher cost than the measure with the lowest average cost per functional habitat index (FHI). Step seven repeats step six to further screen alternatives. Steps eight and nine perform an incremental cost analysis on the measures that were moved forward after going through steps six and seven.

Table 6.3.3-4.
List of Economically Effective Measures for Planning Unit Three

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure C	$381,772	142
Measure D	$310,579	154
Measure B	$469,108	172
Measure G	$407,639	250
Measure H	$336,457	276
Measure E	$643,808	304
Measure F	$494,992	330

Traditionally, these steps are part of the cost effective analysis portion of the "Nine Easy Steps" and are performed on the remaining plans. However, since the Congressional Authority that was given to do the MsCIP Comprehensive study specifically directs the Corps of Engineers not to conduct Incremental Cost Analysis, this analysis will conclude at step six, with measures H and F moving forward for further consideration. Table 6.3.3-5 shows the environmentally cost effective plans for beach and dune placement for planning unit three that will be carried forward for further comparison.

Table 6.3.3-5.
List of Cost Effective Measures for Planning Unit Three

Measures	Total Annual Cost ($)	Total Annual Output (FHI)
Measure AA (No Action)	$0	0
Measure D	$310,579	154
Measure H	$336,45	276
Measure F	$494,992	330
Measure I	$1,452,618	136
Measure J	$1,478,502	216
Measure K	$60,953	248

6.3.3.7 Regional Economic Development (RED)

The purpose of this section is to show the economic impact of the cost effective project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Jackson County, Mississippi. The expenditures for the measures are estimated to be $960,000 for the measure D, $1,530,000 for the measure F, $1,040,000 for the measure H, $4,490,000 for the measure I, $4,570,000 for the measure J, and $1,110,000 for the measure K. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $4,800,000 for the measure D, $7,650,000 for the measure F, $5,200,000 for the measure H, $22,450,000 for the measure I, $22,850,000 for the Measure J measure, and $0 for the Measure K measure (assuming a 50-year period of analysis and an interest rate of 4.875 percent). Tables 6.3.3-6 through 6.3.3-9 show the EIFS model inputs and outputs for the measures ate planning unit three.

Table 6.3.3-6.
EIFS Model Implementation Inputs for LOD2

	Measure D	Measure F	Measure H	Measure I	Measure J	Measure K
Region of Influence (ROI)	Jackson County	Jackson County	Jackson County	Jackson County	Jackson County	Jackson County
Change in Local Expenditures	$960,000	$1,530,000	$1,040,000	$4,490,000	$4,570,000	$1,110,000

Based of the given inputs the outputs are as follows:

Table 6.3.3-7.
EIFS Model Implementation Outputs for LOD2

	Measure D	Measure F	Measure H	Measure I	Measure J	Measure K
Direct Sales Volume	$960,000	$1,530,000	$1,040,000	$4,490,000	$4,570,000	$1,110,000
Induced Sales Volume	$1,075,200	$1,713,600	$1,164,800	$5,028,800	$5,118,400	$1,243,200
Total Sales Volume	$2,035,200	$3,243,600	$2,204,800	$9,518,800	$9,688,400	$2,353,200
Direct Income	$187,225	$298,389	$202,827	$875,665	$891,267	$216,478
Induced Income	$209,691	$334,196	$227,166	$980,744	$998,219	$242,456
Total Income	$396,916	$632,585	$429,992	$1,856,409	$1,889,486	$458,934

Total Employment	58	92	62	269	274	0
Local Population	0	0	0	0	0	0

6.3.3.8 Summary of Cost Effective Measures and their Benefits for Planning Unit Three

Table 6.3.3-10 shows the potential measures that are being carried forward for further consideration. Measures D, H, and F are beach and dune placement measures that depend on the construction of the seawall in order to be implemented. Measures I, J, and K are stand alone measures that do not depend on the seawall for implementation.

Table 6.3.3-10.
List of Measures Carried Forward for Further Evaluation in Planning Unit Three

Measures	Total Annual Cost ($)	Total Annual Output (FHI)	Change in Sales Volume	Change in Income	Change in Employment
Measure AA (No Action)			$0	$0	0
Measure D[1]	$310,579	154	$12,211,200	$2,381,496	69
Measure F[1]	$494,992	330	$19,461,600	$3,795,509	110
Measure H[1]	$336,45	276	$13,228,800	$2,579,954	75
Measure I	$1,452,618	136	$57,112,800	$11,138,455	323
Measure J	$1,478,502	216	$58,130,400	$11,336,913	329
Measure K	$60,953	248	$2,353,200	$458,934	13

6.3.3.9 Public Access and Parking

A public access and parking analysis was conducted on the sections where beach and dune constriction would take place. It was determined that each of the three planning units has sufficient access and parking to satisfy the requirements established in Engineering Regulation (ER) 1165-2-100. Planning unit three has three access points for the Ocean Springs beach area that are all within the required half mile distance and have 300 free parking spaces all within a quarter mile of one of the access points. Addendum C describes the result of the access and parking analysis in greater detail.

6.4 Seawall and Elevated Roadway Area Measures

6.4.1 General

The Seawall and Elevated Roadway area is located in all three planning units just north of the roadways that run parallel to the beach. These areas are denoted by the coastal zone area. In planning unit one, the seawall area includes planning sub-units two, three and four, in planning unit two, planning sub-units eight, ten, thirteen, fifteen, eighteen, and twenty, and in planning unit three the planning sub-units are twenty-one and twenty-two. These areas are all highly populated and include several east/west evacuation routes.

6.4.2 Historic (Pre-Hurricane Katrina) Conditions

The pre-Hurricane Katrina conditions for planning sub-units three and four in planning unit one represented a mostly residential community. The areas in planning unit one included 27,310 tax parcels, of which 15,464 contained an asset with some economic value and 11,846 were vacant land. Of the 15,464 parcels that contain assets, 12,061 were residential one-story, 337 were residential two-story, 237 were mobile homes, 2,419 were commercial, and 410 were municipal. The areas in planning unit two included 34,028 tax parcels, of which 20,028 contained an asset with

some economic value and 14,000 were vacant land. Of the 20,028 parcels that contain assets, 18,628 were residential one-story, 658 were residential two-story, 318 were mobile homes, 256 were commercial, and 168 were municipal. The areas in planning unit three included 17,360 tax parcels, of which 12,705 contained an asset with some economic value and 4,655 were vacant land. Of the 12,705 parcels that contain assets, 11,380 were residential one-story, 315 were residential two-story, 85 were mobile homes, 793 were commercial, and 132 were municipal. Table 6.4-1 summarizes the assets by planning unit for the seawall and elevated roadway area.

Table 6.4-1.
Pre-Hurricane Katrina Economic Asset Characteristics for the Impacted Seawall and Roadway Areas

	Planning Unit One	Planning Unit Two	Planning Unit Three	
Asset Categories	**Assets by Category**	**Assets by Category**	**Assets by Category**	**Total**
Residential	12,398	19,286	11,695	43,379
Mobile Homes	237	318	85	640
Commercial	2,419	256	793	3,468
Municipal	410	168	132	710
Vacant Land	11,846	14,000	4,655	30,501
Total	**27,310**	**34,028**	**17,360**	**78,698**

Figure 6.4-1 denotes the various zones and shows the coastal zone in beige. Figure 6.4-2 shows the planning sub-units of the area by planning unit.

6.4.2.1 Existing (Post-Hurricane Katrina) Conditions

Hurricane Katrina made its Mississippi landfall just west of planning sub-units three and four. It is estimated that the storm destroyed 21,228 structures at least fifty-percent or more in these areas. Of those, 7.903 were destroyed in planning unit one, 12,789 in planning unit two, and 536 were destroyed in planning unit three. Table 6.4-2 displays the destroyed structures by category and by planning unit for these areas.

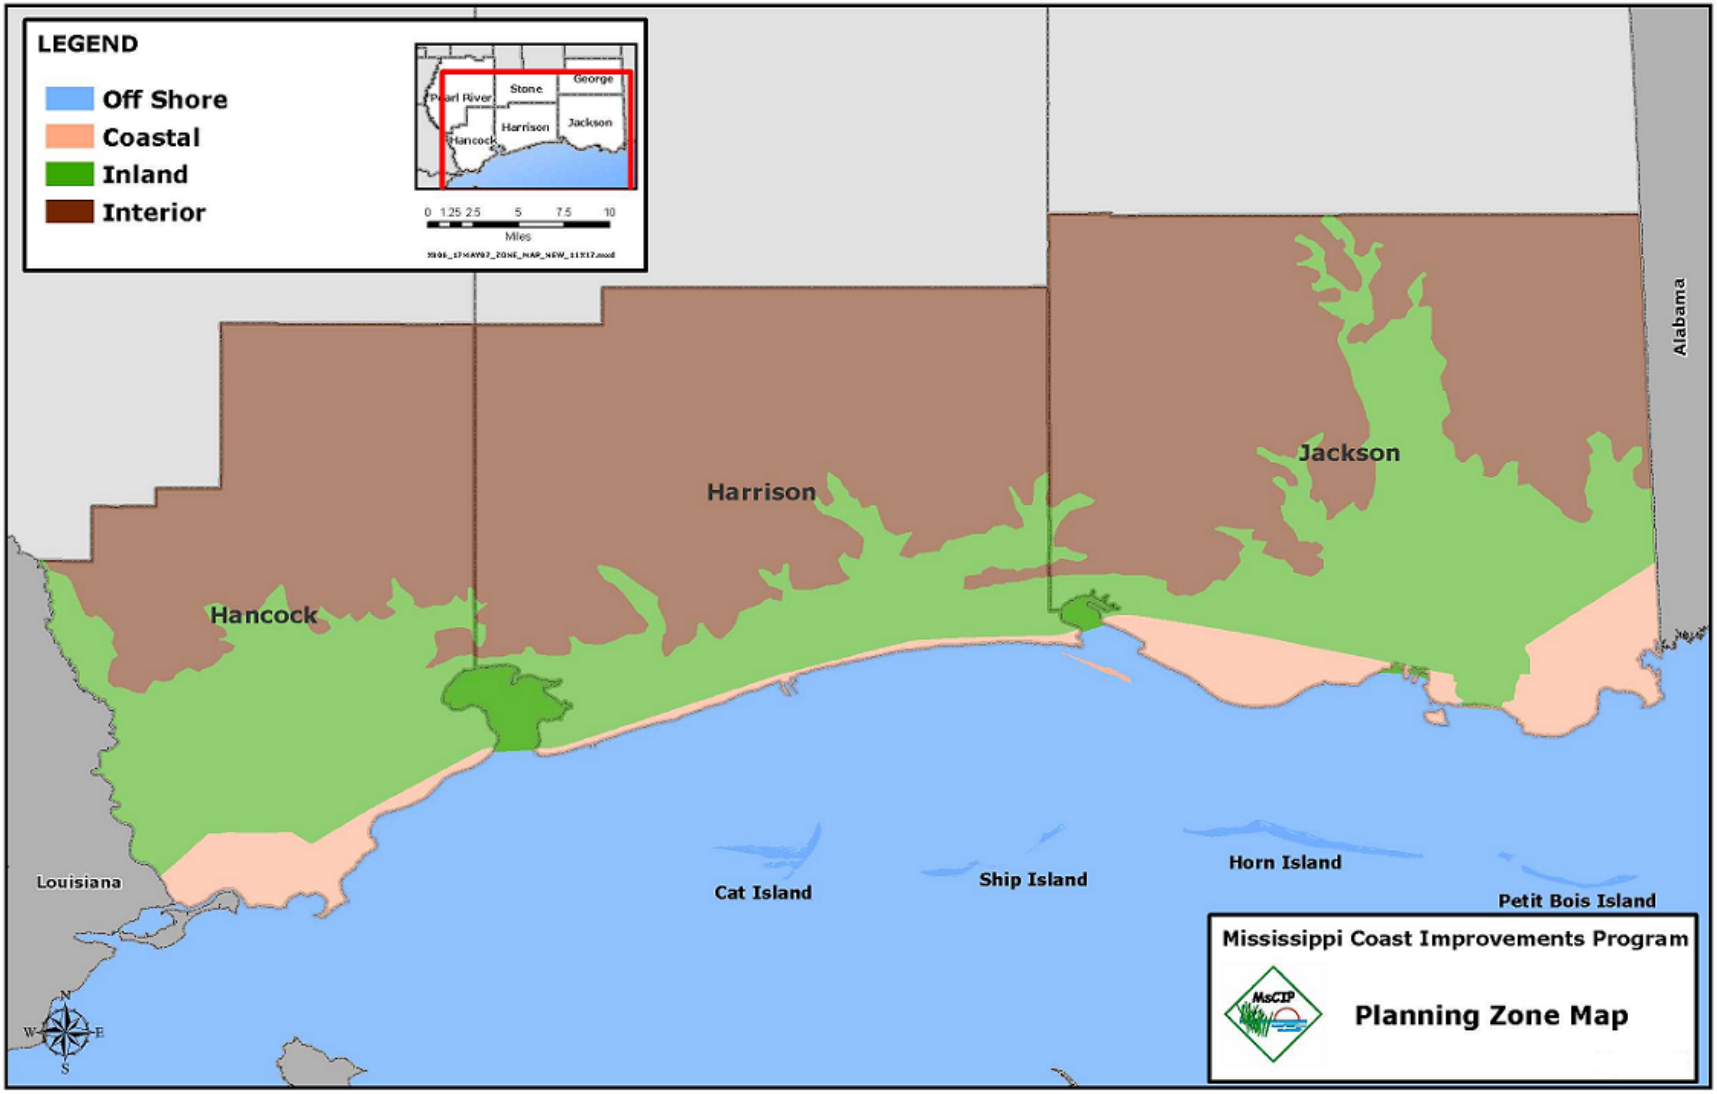

Figure 6.4-1. Planning Zones – Impacted area is the coastal zone

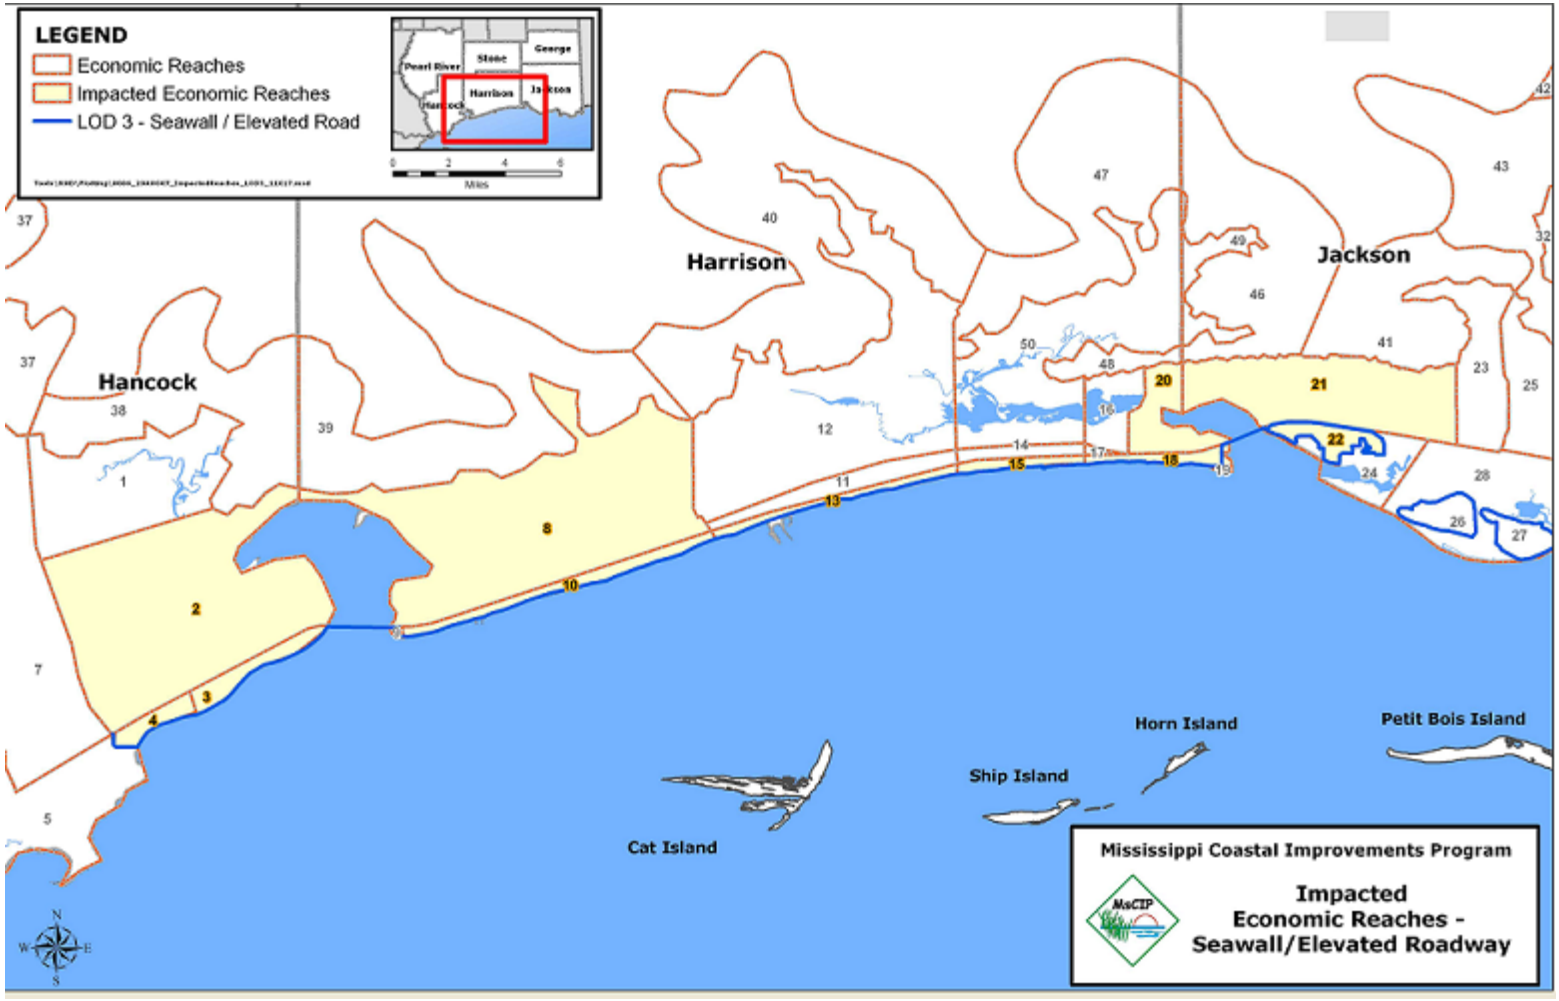

Figure 6.4-2. Planning sub-units in Coastal Area for Planning Unit One, Two, and Three

Table 6.4-2.
Destroyed Structures by Category and Planning Unit

	Planning Unit One	Planning Unit Two	Planning Unit Three	
Asset Categories	**Assets by Category**	**Assets by Category**	**Assets by Category**	**Total**
Residential	6,741	11,106	474	18,321
Mobile Homes	27	111	10	148
Commercial	1,054	1,492	44	2,590
Municipal	81	80	8	169
Total	**7,903**	**12,789**	**536**	**21,228**

6.4.3 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation.

6.4.4 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8-percent was used in estimating average annual benefits and costs.
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.
- Full redevelopment of the area will take place by the base year 2012.

6.4.5 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit one. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A - LOD-3, Seawall and Elevated Roadway

This measure will elevate an existing 2-lane roadway up to an elevation of 11.0-feet NAVD88 in planning unit one, to an elevation of 16.0-feet NAVD88 in planning unit two, and up to an elevation of 11.0-feet NAVD88 in planning unit three. This will include raising an associated seawall, landward slope protection, interior drainage, and pumping stations as required. This measure also requires the installation of surge barriers across St. Louis Bay and Biloxi Bay to elevation 20.0-feet NAVD88. See the Engineering Appendix for more detail on this measure.

- Measure B – Nonstructural One

This measure includes the acquisition and flood proofing (elevate in place) of structures to an ABFE level of protection. See the Nonstructural Appendix for more detail on this measure.

- Measure C – Nonstructural Two

This measure includes the acquisition and flood proofing (elevate in place) of structures to approximately elevation 20.0-feet NAVD88. See the Nonstructural Appendix for more detail on this measure.

- Measure D – Nonstructural Three

This measure includes the acquisition and flood proofing (elevate in place) of structures to approximately elevation 30.0-feet NAVD88. See the Nonstructural Appendix for more detail on this measure. See the Nonstructural Appendix for more detail on this measure.

6.4.6 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.4.6.1 Future Without-Project Conditions

Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the alternatives were evaluated and compared to the without project conditions for three of the six future without project scenarios. Future without-project scenarios one, two, three, four, five and six were used to evaluate the flood damage reduction benefits for this area. These future scenarios were chosen because the redevelopment projected for this area could take the form it was before Hurricane Katrina or it could be redeveloped back as condominiums and condos.

Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Structures will be rebuilt to what they were pre-Hurricane Katrina; residential back to residential, commercial back to commercial, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Inland Barrier area.

Future scenario two is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Structures will be rebuilt to what they were pre-Hurricane Katrina; residential back to residential, commercial back to commercial, etc, with the exception of the water front areas for planning units one and two. In these planning units,

the scenario will address what if commercial and casino redevelopment would occur along the water front and Back Bay areas. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Inland Barrier area.

Future scenario three has the same redevelopment as future scenario one with a maximum relative sea level rise of 2.0-feet depending on location. Equivalent annual damages that could occur under this scenario are $426,040,000 (rounded to the nearest thousand).

Future scenario four has the same redevelopment as future scenario two with a maximum relative sea level rise of 2.0-feet depending on location. Equivalent annual damages that could occur under this scenario are $434,040,000 (rounded to the nearest thousand).

Future scenario five has the same redevelopment as future scenario one with a maximum relative sea level rise of 3.4-feet depending on location. Equivalent annual damages that could occur under this scenario are $475,200,000 (rounded to the nearest thousand). These damages are an 11.54-percent increase over the 2.0-feet relative sea level rise accounted for in future scenario two.

Future scenario six has the same redevelopment as future scenario two with a maximum relative sea level rise of 3.4-feet depending on location. Equivalent annual damages that could occur under this scenario are $483,700,000 (rounded to the nearest thousand). These damages are an 11.44-percent increase over future scenario four with a maximum of 2.0-feet relative sea level rise.

6.4.6.2 Equivalent annual damages Reduced and Residual Damages

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios and the damages incurred with the measure in place. The HECFDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without-project inventory except that footprints of seawall and elevated roadway and the acquisitions were deleted from the inventory and flood proofed (structure to be raised in place) structures were given a specific first floor elevation. The structure inventories for each of the HEC-FDA with-measure runs are as follows:

- Measure A – Seawall and Elevated Roadway

This measure includes the without-project inventory less 1,543 parcels that were deleted out of the inventory. Of those, 411 parcels were estimated to be impacted in planning unit one, 1,004 in planning unit two, and 128 in planning unit three. These parcels represent the footprint of the seawall and elevated roadway across the three planning units and some portion of the total would have to be purchase for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – ABFE Nonstructural

This measure includes the acquisition of 24,411 parcels some with structures and some vacant land, and the flood proofing (elevate structure in place) of 8,053 structures to an elevation ranging from 14.9-feet NAVD88 to 22.4-feet NAVD88 depending on the planning sub-unit the structures is assigned. This plan was formulated by the nonstructural flood proofing committee and details can be found in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE

level of protection is defined as still water elevation, plus wave run-up plus and estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

The equivalent annual damage reduction by measure for the Seawall and Elevated Roadway is shown in table 6.4-3.

Table 6.4-3.
Equivalent Annual Damage Reduction by Future Scenario

Measures	Equivalent Annual Damage Reduction Future 3 ($)	Equivalent Annual Damage Reduction Future 4 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Equivalent Annual Damage Reduction Future 6 ($)
(No Action)	$0	$0	$0	$0
Measure A Seawall/Elevated Roadway	$52,030,000	$54,260,000	$58,090,000	$59,920,000
Measure B ABFE Nonstructural	$200,860,000	$206,490,000	$220,160,000	$226,120,000

Equivalent annual damages reduced are rounded to the nearest thousand dollars.

6.4.6.3 Residual Damages

Residual damages are the equivalent annual damages that still remain even when a project is in place. Residual damages are calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damages is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table". Residual damage by measure is shown in table 6.4-4.

Table 6.4-4.
Residual Damages by Measure and by Future Scenario

Measures	Residual Damages Future 3 ($)	Residual Damages Future 4 ($)	Residual Damages Future 5 ($)	Residual Damages Future 6 ($)
(No Action)	$0	$0	$0	$0
Measure A Seawall/Elevated Roadway	$374,010,000	$379,780,000	$417,110,000	$423,780,000
Measure B ABFE Nonstructural	$225,180,000	$227,550,000	$255,040,000	$257,580,000

Equivalent annual damages reduced are rounded to the nearest thousand dollars.

6.4.7 Environmental Quality (EQ)

6.4.7.1 Impacts of Seawall Elevated Roadway Measure

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1) A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2) A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.4-5 and 6.4-6 show the impacts of the Jackson, Hancock, and Harrison Counties Seawall footprints respectively.

Table 6.4-5.
Wetland Acres Impacted by Jackson County Seawall

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Total
22	0.0	0.7	0.2	0.5	1.4
24	0.6	0.6	0.0	0.0	1.3
Total	**0.6**	**1.4**	**0.2**	**0.5**	**2.7**

Table 6.4-6.
Wetland Acres Impacted by Hancock and Harrison Seawall

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Total
2	0.0	0.0	0.6	3.8	4.4
3	0.0	0.1	0.0	0.0	0.1
4	0.6	0.7	0.8	0.0	2.1
5	0.0	0.4	0.0	5.3	5.6
7	0.0	0.0	0.0	1.9	1.9
10	0.0	4.7	0.0	0.0	4.7
13	0.0	6.4	0.0	0.0	6.4
18	0.0	0.1	0.1	0.0	0.3
Total	**0.6**	**12.4**	**1.5**	**10.9**	**25.4**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the coast wide area can be found in the Environmental Appendix.

6.4.8 Summary of Costs

Table 6.4-7 summarizes the ROM costs at an FY-08 price level by measure for the seawall and elevated roadway impact area.

Table 6.4-7.
Summary of Costs by Measure for Seawall and Elevated Roadway Area

Measures	Implement Cost (FY-08) ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0
Measure A Seawall and Elevated Roadway	$5,002,500,000	$245,979,051	$60,148,000	N/A	$306,127,051
Measure C ABFE Nonstructural	$8,580,261,000	$421,902,000	$110,000	N/A	$422,012,000

6.4.9 Regional Economic Development (RED)

The purpose of this section is to describe the economic impact of the proposed measure on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Hancock, Jackson, and Harrison Counties, Mississippi. The expenditures for the measures are estimated to be $5,002,500,000 for the seawall and elevated roadway measure, $8,580,261,333 for the ABFE nonstructural measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $1,223,235,756 for the seawall and elevated roadway measure, $2,237,081 for the ABFE nonstructural measure based on a 100-year period of analysis and an FY 08 discount rate of 4.875-percent. The EIFS model inputs and outputs for the seawall and elevated roadway area are summarized in tables 6.4-8 through 6.4-11.

Table 6.4-8.
EIFS Model Implementation Costs Inputs for the Seawall and Elevated Area

	Seawall & Elevated Roadway	ABFE Nonstructural
Region of Influence (ROI)	Hancock, Harrison & Jackson Counties	Hancock, Harrison & Jackson Counties
Change in Local Expenditures	$5,002,500,000	$8,580,261,333

Based of the given implementation cost inputs the outputs are as follows:

Table 6.4-9.
EIFS Model Implementation Costs Outputs for the Seawall and Elevated Area

	Seawall & Elevated Roadway	ABFE Nonstructural
Direct Sales Volume	$5,002,500,000	$8,580,261,333
Induced Sales Volume	$5,755,350,000	$9,336,803,805
Total Sales Volume	$10,757,850,000	$17,917,065,137
Direct Income	$1,115,405,211	$1,965,390,069
Induced Income	$1,274,630,230	$2,124,627,724
Total Income	$2,390,035,440	$4,090,017,793
Direct Employment	31,133	52,577
Induced Employment	35,915	57,351
Total Employment	67,048	109,928
Local Population	0	0

Table 6.4-10.
EIFS Model O&M Costs Inputs for the Seawall and Elevated Area

	Seawall & Elevated Roadway	ABFE Nonstructural
Region of Influence (ROI)	Hancock, Harrison & Jackson Counties	Hancock, Harrison & Jackson Counties
Change in Local Expenditures	$1,223,235,756	$2,237,081

Based of the given O&M cost inputs the outputs are as follows:

Table 6.4-11.
EIFS Model O&M Costs Outputs for the Seawall and Elevated Area

	Seawall & Elevated Roadway	ABFE Nonstructural
Direct Sales Volume	$1,223,235,756	$2,237,081
Induced Sales Volume	$1,393,527,224	$2,590,946
Total Sales Volume	$2,616,762,980	$4,828,027
Direct Income	$274,711,471	$484,736
Induced Income	$310,746,337	$558,828
Total Income	$585,457,808	$1,043,565
Direct Employment	7,602	14
Induced Employment	8,684	16
Total Employment	16,286	30
Local Population	0	0

6.5 Evaluation of Pearlington Area Measures

6.5.1 General

The Pearlington area, shown in figure 6.5-1, is located in the western area of planning unit one along the Pearl River. The area is denoted as planning sub-unit six and is depicted in the figure below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As shown in Table 6.5-1, it was estimated from the field inventorying process that planning sub-unit six included 1,155 tax parcels, of which 1,152 contained a structure with some economic value and 3 ere vacant land. Of those 1,152 parcels that contain structures, 1,043 were residential one-story, 5 ere residential two-story, 17 were mobile homes, 64 were commercial, and 23 were municipal.

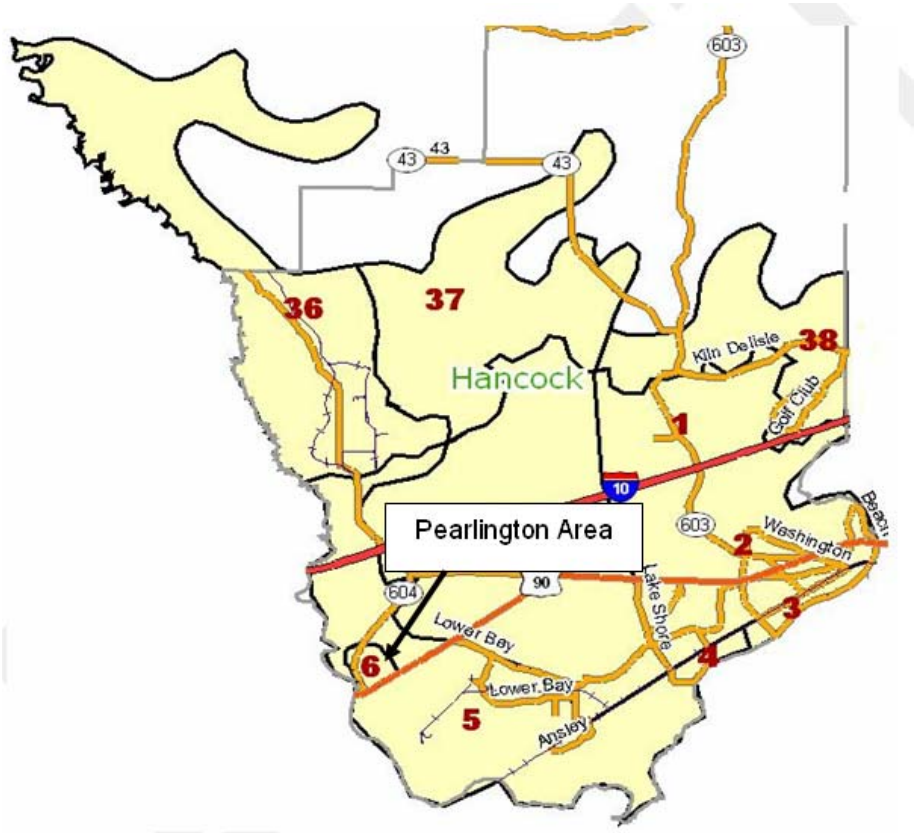

Figure 6.5-1. Pearlington Area – Planning Sub-unit Six

Table 6.5-1.
Pre-Hurricane Katrina Estimate of Structures
for the Pearlington Area Planning Sub-unit Six

Asset Categories	Assets by Category
Residential	1,048
Mobile Homes	17
Commercial	64
Municipal	23
Vacant Land	3
Total Tax Parcels	**1,155**

6.5.2 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation.

6.5.3 Assumptions

The following assumptions were used in this analysis:

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs.
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

6.5.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit one. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

Measure A - Pearlington Ring Levee
This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.

Measure B - Pearlington Ring Levee
This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.

Measure C – Pearlington Nonstructural One
This measure includes the acquisition and flood proofing (elevate-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

Measure D – Pearlington Nonstructural Two
This measure includes the acquisition and flood proofing of structures to approximately elevation 20.0-feet NAVD88.

Measure E – Pearlington Nonstructural Three
This measure includes the acquisition and flood proofing of structures to approximately elevation 30.0-feet NAVD88.

Figure 6.5-2 shows the measures for the Pearlington Area (planning sub-unit six); the red line represents the approximate footprint of the ring levees, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

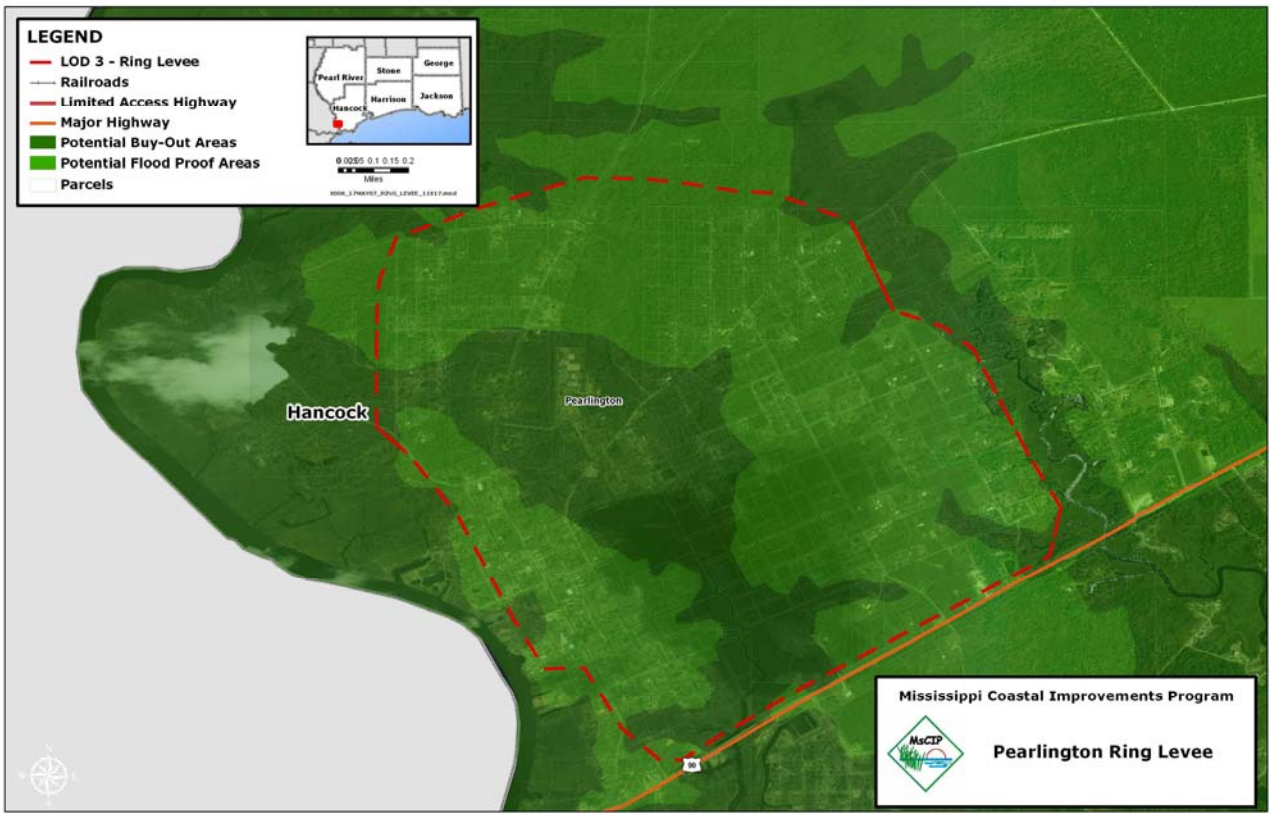

Figure 6.5-2. Display of Potential Measures for the Pearlington Area (Planning Sub-Unit Six)

6.5.5 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.5.5.1 Existing Conditions Post-Hurricane Katrina)

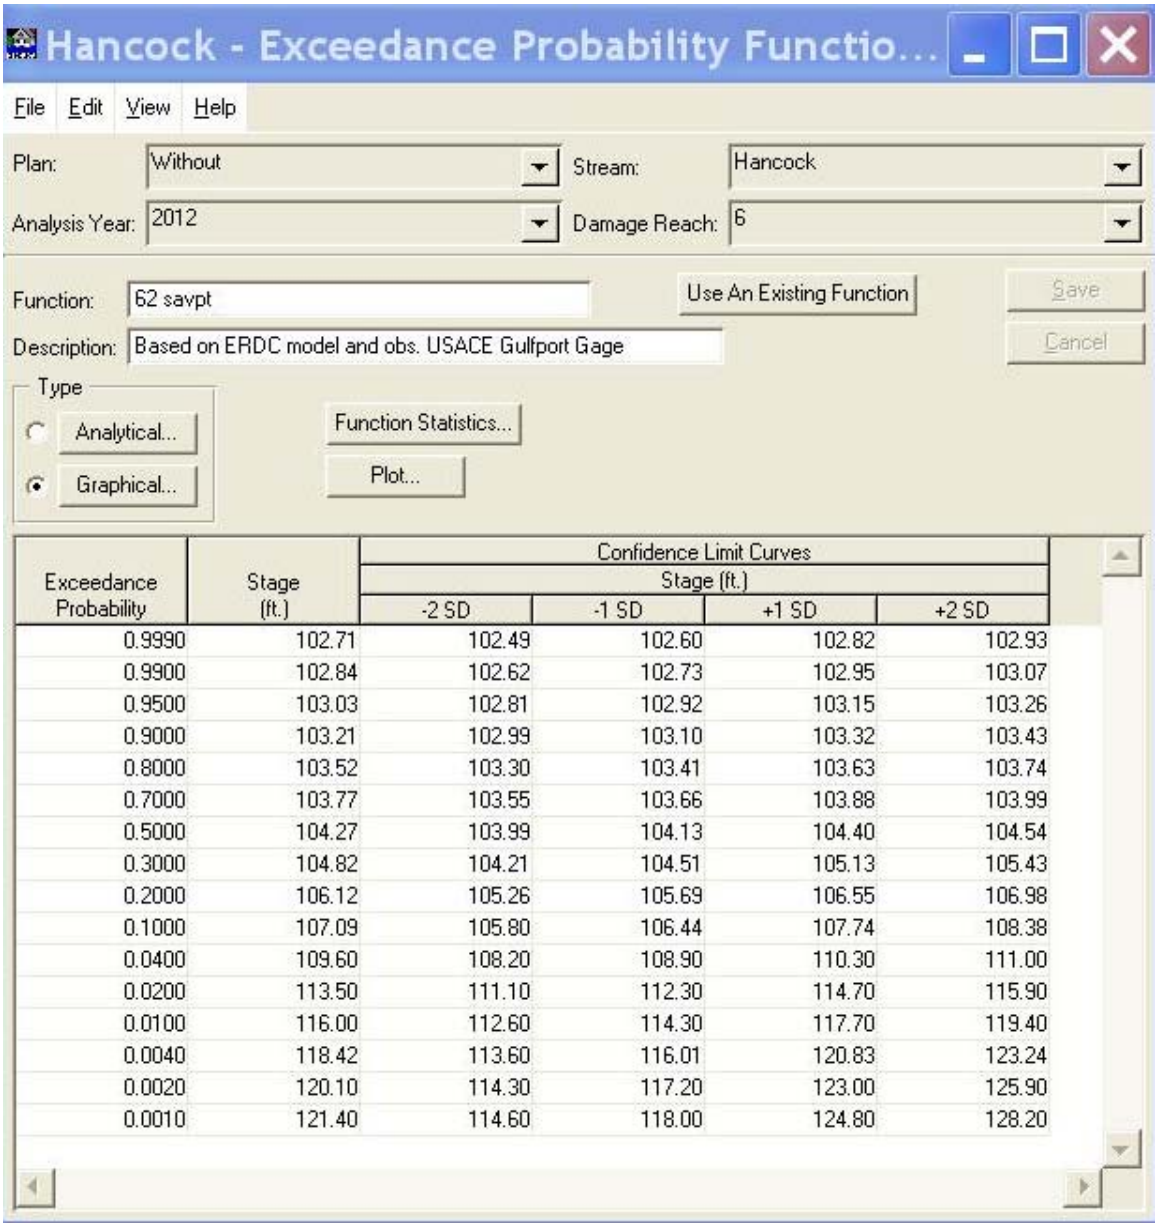
The effects of Hurricane Katrina storm surge were devastating to the Pearlington Area. Peak water elevation in the area ranged from 16-to-19-feet NAVD88. It is estimated that between 95 and 99-percent of the structures in the area sustained significant inundation damage (fifty-percent or more). Destroyed residences and commercial structures have displaced the majority of the residences within the area. Expected redevelopment of the area is described in the following section.

6.5.5.2 Future Without-Project Conditions

Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).

Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.5-2 shows structures by category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there is one structure with an elevation of 1-foot or lower, there are ten structures with an elevation of 2-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Pearlington area.

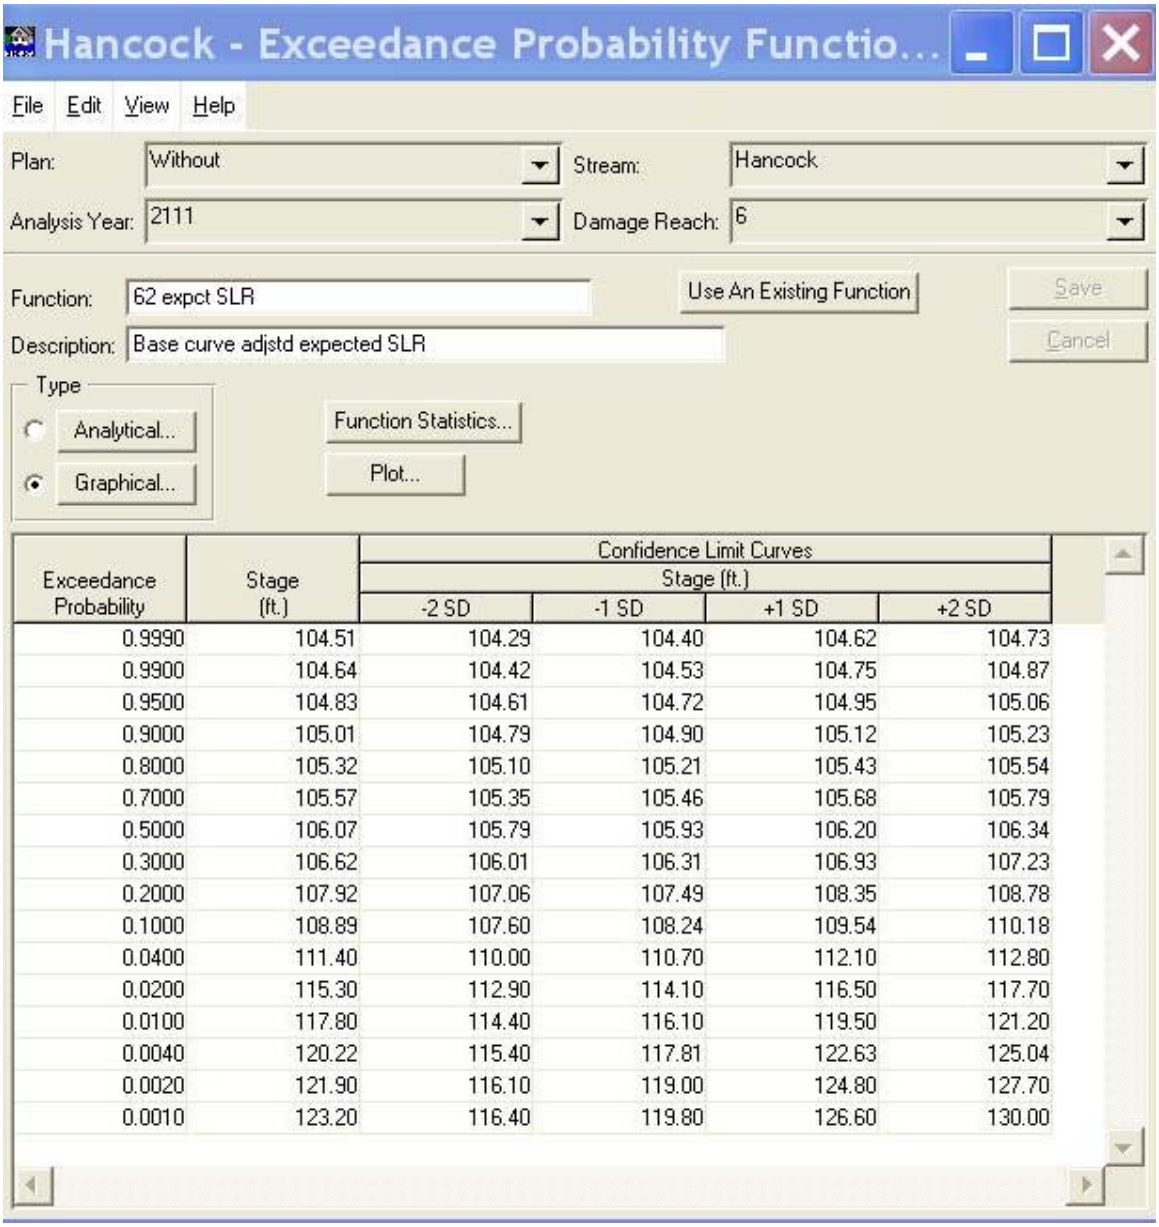
Table 6.5-2.
Cumulative Structures by Category and by Estimated First Floor Elevation Future Scenarios One, Three, and Five Applicable for Base Year and Most Likely Future Years



Estimated First Floor Elevation (NAVD88)	Residential	Mobile Homes	Commercial	Municipal	Total
1-foot	1	0	0	0	1
2-foot	10	0	0	0	10
3-foot	22	0	0	0	22
4-foot	35	0	0	0	35
5-foot	51	0	0	0	51
6-foot	75	0	0	0	75
7-foot	125	0	0	0	125
8-foot	214	0	0	0	214
9-foot	351	0	0	0	351
10-foot	425	0	0	0	425
11-foot	452	0	0	0	452
12-foot	459	0	0	0	459
13-foot	460	0	0	0	460
14-foot	460	0	0	0	460
15-foot	460	0	0	0	460
16-foot	460	0	0	0	460
17-foot	460	0	0	0	460
18-foot	460	0	0	0	460
19-foot	460	0	0	0	460
20-foot	1,048	17	64	23	1,152
Total	**1,048**	**17**	**64**	**23**	**1,152**

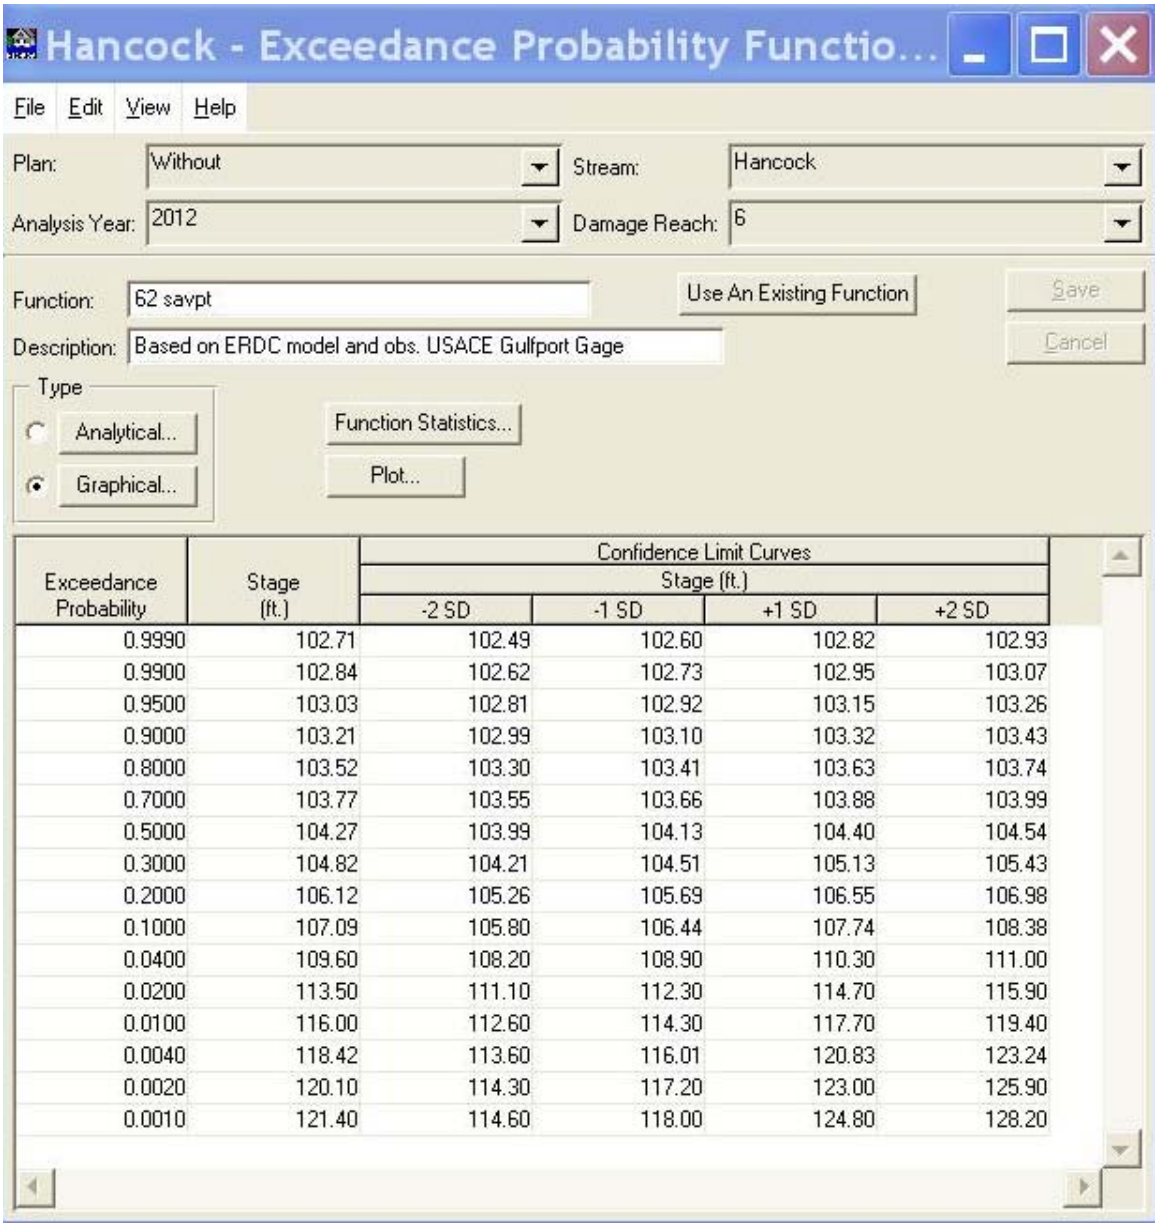
Estimated first floor elevations can be compared to the exceedance probability functions or both future scenarios three and five.

Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure;



commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $12,885,000 (rounded to the nearest thousand). The total number of structures in this scenario are the same as in scenario one and can be seen above in table 6.5-2. Figures 6.5-3 and 6.5-4 depict the base year and most likely future year exceedance probability functions for the Pearlington area (planning sub-unit six). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.5-4 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $14,205,000 (rounded to the nearest thousand). These damages represent approximately a ten-percent (10.24%) increase over the expected relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.5.2. Figures 6.5-5 and 6.5-6 depict the base year and most likely future year exceedance probability functions for the Pearlington area (planning sub-unit six). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.5-5 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.



Exceedance Probability	Stage (ft.)	Confidence Limit Curves Stage (ft.) -2 SD	-1 SD	+1 SD	+2 SD

Figure 6.5-6 Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Pearlington Area – Includes an adjustment for relative sea level rise

6.5.5.3 Equivalent annual damages Reduced and Equivalent Annual Residual Damages

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HEC-FDA model was run for each measure to determine the damages reduced as compared to the without-project scenario. In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures

(structures to be raised in place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Pearlington Ring Levee at elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 138 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Pearlington Ring Levee at elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 138 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the parcels identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Pearlington ABFE Nonstructural One

This measure includes the acquisition of 539 parcels that include a structure and the flood proofing (raise structure in place) of 588 structures to elevation of 19.35-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up, plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

- Measure D – Pearlington Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 950 parcels that include a structure and the flood proofing (raise structure in place) of 177 structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 20.0-feet NAVD88.

- Measure E – Pearlington Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 1,127 parcels that include a structure. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damage is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.5-3 summarizes the without project damages, damages reduced, and the residual damage by measure and by future scenario.

Table 6.5-3.
Summary of Damages by Potential Measure and Applicable Future Scenario

Measures	Equivalent Annual Damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent annual damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20Ft Ring Levee	$12,885,000	$11,894,000	$991,000	$14,205,000	$13,088,000	$1,117,000
Measure B 30FT Ring Levee	$12,885,000	$12,267,000	$618,000	$14,205,000	$13,228,000	$977,000
Measure C ABFE Nonstructural	$12,885,000	$12,260,000	$625,000	$14,205,000	$13,520,000	$685,000
Measure D 20FT Nonstructural	$12,885,000	$ 12,813,000	$ 72,000	$14,205,000	$ 14,123,000	$ 82,000
Measure E 30FT Nonstructural	$12,885,000	$12,885,000	$0	$14,205,000	$14,205,000	$0

Damages are rounded to the nearest thousand dollars.

6.5.6 Environmental Quality (EQ)

6.5.6.1 Impacts of Ring Levee Measures

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.5-4 and 6.5-5 show the impacts of the Pearlington ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.5-4.
Wetland acres impacted by elevation 20' Pearlington ring levee

Reach ID	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
5	1.1	0.6	0.1	1.9
6	2.7	0.7	0.0	3.4
Total	**3.8**	**1.3**	**0.1**	**5.3**

Table 6.5-5.
Wetland acres impacted by elevation 30' Pearlington ring levee

Reach ID	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
5	2.2	1.2	0.2	3.6
6	3.3	1.0	0.0	4.3
Total	**5.5**	**2.2**	**0.2**	**7.9**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Pearlington area can be found in the Environmental Appendix.

6.5.7 Summary of Costs

Table 6.5-6 summarizes the ROM costs at an FY-08 price level by measure for the Pearlington Area (planning sub-unit six).

Table 6.5-6.
Summary of Costs by Measure for the Pearlington Area

Measures	Implement Cost (FY-08) ($)	Capital Recovery Factor	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	0.049171225	$0	$0	$0	$0
Measure A 20FT Ring Levee	$104,800,000	0.049171225	$5,153,000	$1,320,000	N/A	$6,473,000
Measure B 30FT Ring Levee	$120,200,000	0.049171225	$5,910,000	$1,526,000	N/A	$7,436,000
Measure C ABFE Nonstructural	$274,808,000	0.049171225	$13,513,000	$10,000	N/A	$13,523,000
Measure D 20FT Nonstructural	$152,102,000	0.049171225	$7,479,000	$10,000	N/A	$7,489,000
Measure E 30FT Nonstructural	$152,102,000	0.049171225	$7,479,000	$10,000	N/A	$7,489,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns. Numbers are rounded to the nearest thousand.

6.5.8 Regional Economic Development (RED)

The purpose of this section is to describe the economic impact of the proposed measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Hancock County, Mississippi. The expenditures for the measures are estimated to be $104,800,000 for the 20.0-feet NAVD88 ring levee measure, $120,200,000for the 30.0-feet NAVD88 ring levee measure, $274,808,000 for the ABFE nonstructural measure, $152,102,000 for the 20.0-feet NAVD88 nonstructural measure, and $152,102,000 for the 30.0-feet NAVD88 nonstructural measure. Moreover, the total Operation and

Maintenance (O&M) expenditures, which are based on the total present worth of O&M costs over the period of analysis, are estimated to be $26,845,000 for the 20.0-feet NAVD88 ring levee measure, $31,034,000 for the 30.0-feet NAVD88 ring levee measure, $203,000 for the ABFE nonstructural measure, $203,000 for the 20.0-feet NAVD88 nonstructural measure, and $203,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100- year period of analysis and an interest rate of 4.875-percent). The following tables summarize the inputs and outputs of the EIFS model by measure.

Table 6.5-7.
EIFS Model Construction Costs Inputs for the Pearlington Area

	20-Foot Ring Levee	30-Foot Ring Levee	ABFE Nonstructural	20-Foot Nonstructural	30-Foot Nonstructural
Region of Influence (ROI)	Hancock County	Hancock County	Hancock County	Hancock County	Hancock County
Change in Local Expenditures	$104,800,000	$120,200,000	$387,900,000	$152,102,000	$152,102,000

Based of the given inputs the outputs are as follows:

Table 6.5-8.

6.6 Admiral Island Ecosystem Restoration Measures

This section describes the evaluation of ecosystem restoration measures at the Admiral Island area that is located within planning sub-unit two, which is part of planning unit one. The total area includes approximately 400 acres of state owned land. This area was selected for ecosystem restoration using the Decision Support System, a GIS based model created by the Corps' Engineer Research and Development Center (ERDC). For more details on the selection process for ecosystem restoration sites see the economic appendix. Figure 6.6-1 shows the location of the Admiral Island area.

6.6.1 Formulation of Alternatives

6.6.1.1 Assumption

In order for the Admiral Island site to undergo ecosystem restoration, it is assumed that there will be mandatory buy-outs of properties and removal of all existing structures within the footprint of the site. These buy-outs will be part of the flood damage reduction alternative and not this ecosystem restoration alternative.

6.6.1.2 Objectives

The following ecosystem restoration objectives were developed:

- Restore the natural hydrology
- Provide storm surge protection
- Restore native tidal wetland plant communities
- Provide fish and tidal wildlife habitat
- Prevent saltwater intrusion

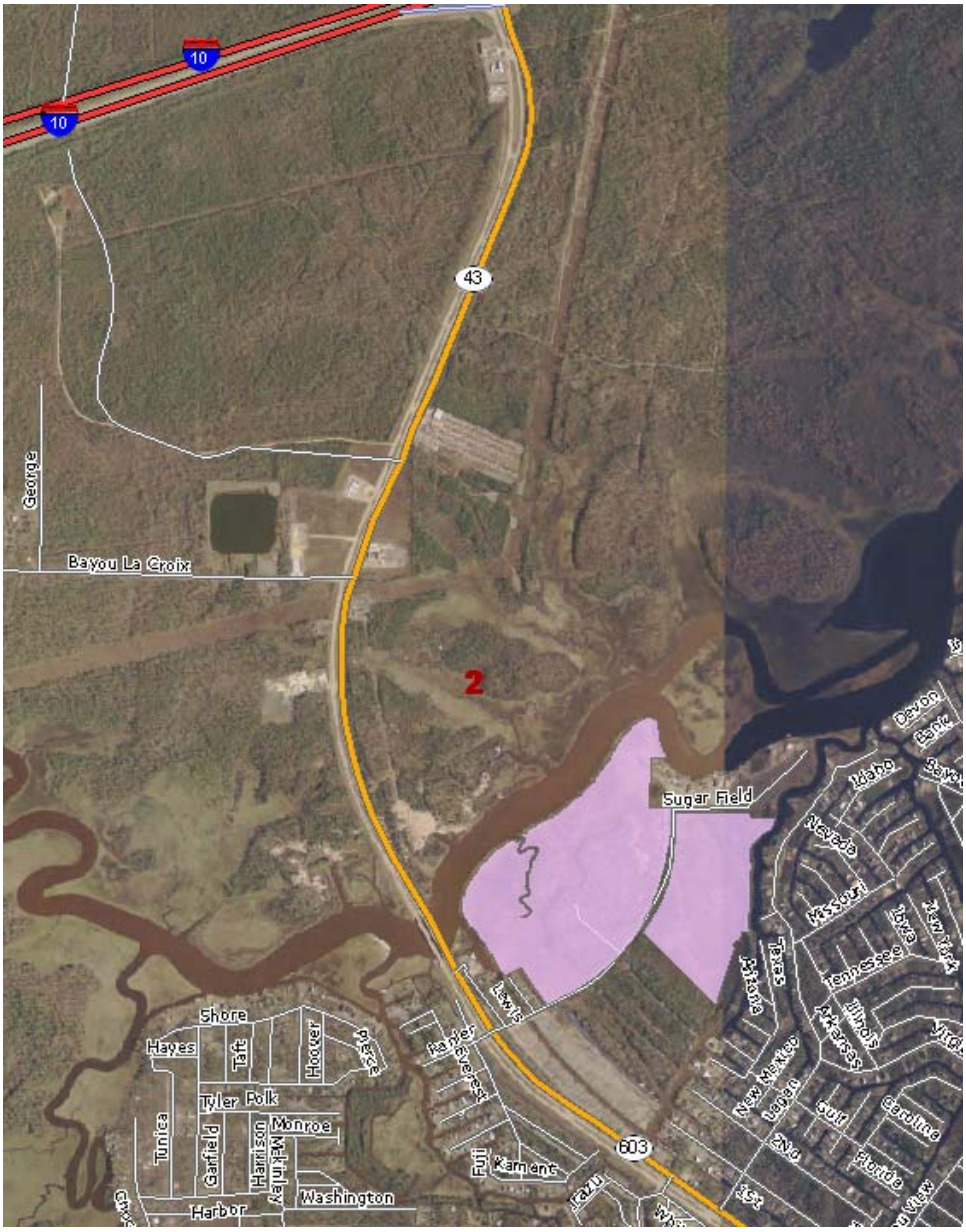

Figure 6.6-1. Location of the Admiral Island Restoration Area

6.6.1.3 Ecosystem Restoration Management Measures

Proposed restoration management measures are listed in Table 6.6-1. Narrative descriptions of each management measure follow this table.

Table 6.6-1.
Ecosystem Restoration Management Measures

Management Measure	Description
No Action	No Action
1	Excavate Old Fill Material
2	Remove Exotic Species
3	Fill Existing Artificial Ditches
4 *a* *b* *C*	Plant Native Vegetation - 0.5 meter spacing - 1.0 meter spacing - 2.0 meter spacing

6.6.1.4 Excavate Old Fill Material (1)

This management measure must be included in all alternatives for the restoration to be successful. It includes 90-95 percent removal of existing exotic species in the excavated areas. This measure positively affects the hydrologic regime.

6.6.1.5 Remove Exotic Species from Non-Excavated Areas and Maintenance of Exotics in All Areas over the Project Life (2)

This management measure must be included in all alternatives for the restoration to be successful. It includes 100 percent removal of exotic species from non-excavated areas over the life of the project. The exotic species include Chinese Tallow, Phragmites, and Cogon Grass. This measure positively affects the percentage of the area covered by exotic species.

6.6.1.6 Fill Existing Artificial Ditches and Channels (3)

This management measure does not need to be included in all alternatives for the restoration to be successful. It includes 100 percent removal of existing artificial ditches and channels. This measure provides additional positive affects to the hydrologic regime.

6.6.1.7 Plant Native Vegetation (4)

The types of native vegetation that will be planted include Spartina alterniflora (Smooth Cordgrass) at the seaward edge of marsh; Juncus roemerianus (Black Needle Rush) at a just slightly higher elevation; and Spartina patens (Saltmeadow Cordgrass) at the next slightly higher elevation.

This management measure must be included in all alternatives for the restoration to be successful. There are three different planting density options: (a) 0.5 meter spacing, (b) 1.0 meter spacing, and (c) 2.0 meters spacing. Planting emergent tidal marsh at varying densities will result in obtaining desired environmental output at varying years and costs. It is estimated that 2 re-planting efforts would be required for the two least dense plantings: 2.0 meters and 1.0 meter spacing. It is estimated that the 0.5 meter spacing will achieve full benefits in about 5 years while the 1.0 meter spacing and 2.0 meter spacing will achieve full benefits in about 7 and 10 years, respectively.

This measure affects the percent cover by woody plant species, wildlife habitat diversity, vegetation height, wetland indicator status and the mean percent cover emergent plant species.

6.6.1.8 Ecosystem Restoration Alternatives

These four management measures were combined to create six alternatives. Each alternative includes the mandatory management measures of excavating old fill material, removing exotic plant species from non-excavated areas, and planting native vegetation. Since there are three different planting densities, three alternatives are created with this combination of management measures. When the management measure of filling existing artificial ditches is added to this combination, this creates another three alternatives.

All alternatives will restore 123 acres. Alternative 1 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, planting native vegetation at a density of 0.5 meters, and filling existing artificial ditches. Alternative 2 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, planting native vegetation at a density of 1.0 meter, and filling existing artificial ditches. Alternative 3 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, planting native vegetation at a density of 2.0 meter, and filling existing artificial ditches. Alternative 4 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas and planting native vegetation at a density of 0.5 meters. Alternative 5 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas and planting native vegetation at a density of 1.0 meter. Alternative 6 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas and planting native vegetation at a density of 2.0 meters. Figure 6.6-2 shows the location of the Admiral Island restoration site. Table 6.6-2 displays a description of each ecosystem restoration alternative.

Figure 6.6-2 Admiral Island restoration site

Table 6.6-2.
Ecosystem Restoration Alternatives

Alternative	Management Measure	Description
0	No Action	No Action
1	1 + 2 +3+ 4a	Excavate Fill Remove Exotics Plant at Density 0.5m Fill Ditches
2	1 + 2 + 3+4b	Excavate Fill Remove Exotics Plant at Density 1.0m Fill Ditches

4	1 + 2 + 4a	Excavate Fill Remove Exotics Plant at Density 0.5m
5	1 + 2 + 4b	Excavate Fill Remove Exotics Plant at Density 1.0m
6	1 + 2 + 4c	Excavate Fill Remove Exotics Plant at Density 2.0m

6.6.1.9 Benefits

Benefits are measured in terms of Average Annual Functional Units (AAFU). The Hydrogeomorphic (HGM) approach was used to assess wetland function. A HGM assessment was performed in 2000 using the Regional Guidebook for Applying the HGM Approach to Assessing Wetland Functions of Wet Pine Flats on Mineral Soils in the Atlantic and Gulf Coastal Plains. Results from this assessment were used to establish baseline (current) conditions and, ultimately, to measure the functional unit benefits resulting from different restoration alternatives. Table 6.6-3 displays the AAFU net benefits for each alternative. The AAFU net benefit was calculated as the difference between the total functional units for the ecosystem restoration alternative and the total functional units for the no action alternative.

Table 6.6-3.
Summary of Benefits

Alternative	Alternative Description	Net AAFU Net Benefits
No Action	No Action	0
Alternative 1	Excavate Fill Remove Exotics Plant at Density 0.5m Fill Ditches	61
Alternative 2	Excavate Fill Remove Exotics Plant at Density 1.0m Fill Ditches	60
Alternative 3	Excavate Fill Remove Exotics Plant at Density 2.0m Fill Ditches	59
Alternative 4	Excavate Fill Remove Exotics Plant at Density 0.5m	51
Alternative 5	Excavate Fill Remove Exotics Plant at Density 1.0m	50.5
Alternative 6	Excavate Fill Remove Exotics Plant at Density 2.0m	49

6.6.1.10 Costs

The rough order magnitude (ROM) first costs of construction, which do not include interest during construction, include excavating 916,483 cubic yards of old fill material for $10,998,000 and planting native vegetation at densities of 0.5m, 1m and 2.0m spacing for $3,571,000, $1,786,000 and $893,000, respectively. The cost of filling ditches with 7,000 cubic yards of material is estimated at approximately $35,000. Herbicide application by hand to 62 acres of land not excavated is estimated at approximately $893,000. Mobilization and demobilization are estimated at approximately $2,400,000, and miscellaneous site items are estimated at approximately $1,000,000. A contingency of 25 percent and lands and damages costs of $25,000 were added to the construction cost. This cost was increased by an 8 percent planning, Engineering and Design (PED) cost and a 6 percent Construction Management cost.

For each alternative, these first costs of construction are presented in Table 6.6-4 in OCTOBER 2007 dollars along with the Interest During Construction (IDC), investment cost (first cost plus the IDC), Average Annual Investment Cost (AAIC), Average Annual Operations and Maintenance (AAO&M) cost and, ultimately, the Average Annual Costs (AAC).

Table 6.6-4.
Summary of Costs by Measure for Admiral Island Area

Alternative	Alternative Description	Implement-ation Cost (FY-08)	IDC	Investment Cost	AAIC	AAO&M	AAC
0	No Action	$0	$0	$0	$0	$0	$0
1	Excavate Fill Remove Exotics Plant at Density 0.5m Fill Ditches	$26,340,000	$580,000	$26,920,000	$1,447,000	$2,000	$1,449,000
2	Excavate Fill Remove Exotics Plant at Density 1.0m Fill Ditches	$23,790,000	$530,000	$24,320,000	$1,306,000	$58,000	$1,364,000
3	Excavate Fill Remove Exotics Plant at Density 2.0m Fill Ditches	$22,490,000	$500,000	$22,990,000	$1,235,000	$58,000	$1,293,000
4	Excavate Fill Remove Exotics Plant at Density 0.5m	$26,280,000	$580,000	$26,860,000	$1,443,000	$2,000	$1,445,000
5	Excavate Fill Remove Exotics Plant at Density 1.0m	$23,720,000	$530,000	$24,250,000	$1,302,000	$58,000	$1,360,000
6	Excavate Fill Remove Exotics Plant at Density 2.0m	$22,440,000	$500,000	$22,900,000	$1,232,000	$58,000	$1,290,000

Note: Numbers are rounded to the nearest thousand.

First costs of construction are used along with the duration of 12 months of construction and a discount rate of 4.875 percent to calculate IDC. The sum of the first costs of construction and IDC cost equal the investment cost. This cost is amortized at the Fiscal Year (OCTOBER) 2007 Federal discount rate of 4.875 percent over a 50-year economic period of analysis to calculate the AAIC. AAO&M costs for monitoring in years 2 through 6 and re-planting in years 3 and 5 were present valued and amortized at an interest rate of 4.875 percent over a 50-year economic period of analysis. The sum of the AAIC and AAO&M cost equal the AAC.

6.6.2 Comparison of Alternatives

Table 6.6-5 displays all alternatives with their respective AAC and AAFU in increasing order of AAFU.

To determine if an alternative is cost effective, economically inefficient alternatives must first be identified and eliminated. An economically inefficient alternative is an alternative that cost more for the same level of benefit. No alternatives are eliminated for the reason of economic inefficiency because each alternative produces a different level of benefit.

Table 6.6-5.
All Alternatives: AAC and AAFU for Admiral Island

Alternative	AAC	AAFU
No Action	$0	0
6	$1,290,000	49
5	$1,360,000	50.5
4	$1,445,000	51
3	$1,293,000	59
2	$1,364,000	60
1	$1,449,000	61

Note: The AAC values are rounded to the nearest thousand.

Lastly, economically ineffective alternatives are identified and eliminated to determine which alternatives are cost effective. An economically ineffective alternative is an alternative that will produce less benefit at an equal or greater cost than a subsequent alternative. The AAFU benefits are place in ascending order and a pair-wise comparison of the benefits and costs is conducted to eliminate economically ineffective alternatives.

As shown in Table 6.6-6, the two shaded alternatives, 5 and 6, were eliminated because they produced less benefit at greater cost than a subsequent alternative. For example, Alternative 4 produces 51 AAFU at an AAC of $1,445,000 while Alternative 3 produces 59 AAFU at an AAC $1,293,000. Alternative 4 produces less AAFU at a greater cost than Alternative 3. Therefore, Alternative 4 is eliminated. As shown in Table 6.6-7 and plotted in Figure 6.6-3, the cost effective alternatives are Alternative 6, Alternative 3, Alternative 2, and Alternative 1.

Table 6.6-6.
Elimination of Economically Ineffective Alternatives

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
6	Excavate Fill Remove Exotics Plant at Density 2.0m	$1,290,000	49	Yes
5	Excavate Fill Remove Exotics Plant at Density 1.0m	$1,360,000	50.5	No
4	Excavate Fill Remove Exotics Plant at Density 0.5m	$1,445,000	51	No
3	Excavate Fill Remove Exotics Plant at Density 2.0m Fill Ditches	$1,293,000	59	Yes
2	Excavate Fill Remove Exotics Plant at Density 1.0m Fill Ditches	$1,364,000	60	Yes
1	Excavate Fill Remove Exotics Plant at Density 0.5m Fill Ditches	$1,449,000	61	Yes

Note: The AAC values are rounded to the nearest thousand.

Table 6.6-7.
Cost Effective Alternatives

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
6	Excavate Fill Remove Exotics Plant at Density 2.0m	$1,290,000	49	Yes
3	Excavate Fill Remove Exotics Plant at Density 2.0m Fill Ditches	$1,293,000	59	Yes
2	Excavate Fill Remove Exotics Plant at Density 1.0m Fill Ditches	$1,364,000	60	Yes
1	Excavate Fill Remove Exotics Plant at Density 0.5m Fill Ditches	$1,449,000	61	Yes

Note: The AAC values are rounded to the nearest thousand.

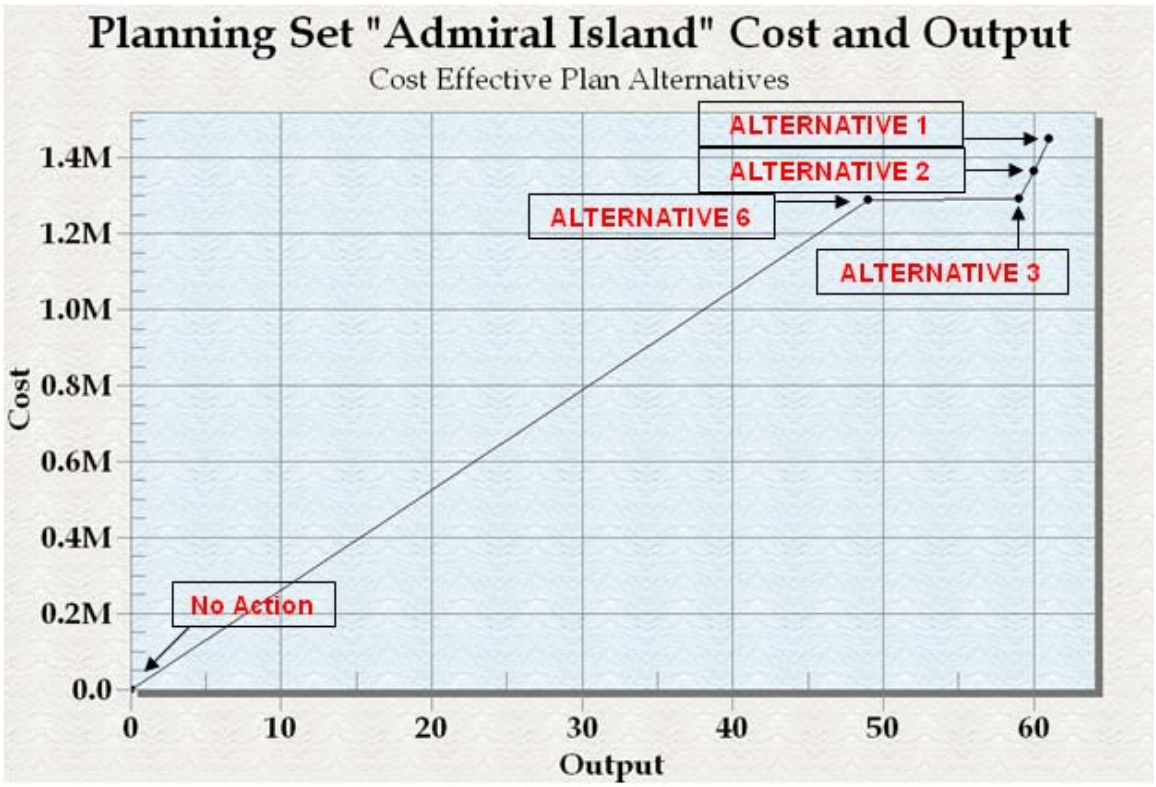

Figure 6.6-3 Display of Cost Effective Alternatives for the Admiral Island Area

6.6.3 Regional Economic Development (RED) Benefits

6.6.3.1 Socioeconomic Impacts using the Economic Impact Forecast System

The purpose of this analysis is to determine the economic impact of the proposed project alternatives on business (sales volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Hancock County, Mississippi. The expenditures for the alternatives are estimated to be $26,300,000for Alternative 1, $23,800,000 for the Alternative 2, $22,500,000for Alternative 3, and $22,400,000 for Alternative 6. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $43,000for Alternative 1, $1,075,000 for Alternative 2, $1,075,000 for Alternative 3, and $1,075,000 for Alternative 6, (assuming a 50 year period of analysis and an interest rate of 4.875 percent). Tables 6.6-8 through 6.6-11 summarize the EIFS model inputs and outputs for the cost effective measures at Admiral Island.

Table 6.6-8.
EIFS Model Implementation Inputs for Admiral Island Ecosystem

	No Action	Alternative 1	Alternative 2	Alternative 3	Alternative 6
Region of Influence (ROI)	Hancock County	Hancock County	Hancock County	Hancock County	Hancock County
Change in Local Expenditures	$0	$26,300,000	$23,800,000	$22,500,000	$22,400,000

Based of the given inputs the outputs are as follows:

Table 6.6-9.

6.7 Evaluation of Turkey Creek Ecosystem Restoration Measures

This section describes the evaluation of ecosystem restoration measures at the Turkey Creek area that is located within planning sub-unit 12, which is part of planning unit two. The total area includes 879 acres. There are no structures within the area, and the acquisition of the parcels would have to occur before the implementation of any of the alternatives. This area was selected for ecosystem restoration using the Decision Support System, a GIS based model created by the Corps' Engineer Research and Development Center (ERDC). For more details on the selection process for ecosystem restoration sites see the Economic Appendix. Figure 6.7-1 shows the location of the Turkey Creek area.

6.7.1 Formulation of Alternatives

6.7.1.1 Assumption

In order for the Turkey Creek site to undergo ecosystem restoration, it is assumed that there will be mandatory buy-outs of required properties in the site footprint. The costs of these buy-outs are accounted for in the flood damage reduction alternative and not in this ecosystem restoration alternative. However, there are non-building structures that require removal and disposal. These costs result from and are included in this ecosystem restoration alternative.

6.7.1.2 Objectives

The following objectives were developed for this ecosystem restoration study:

- Restore native vegetation
- Restore natural hydrology
- Restore fish and wildlife habitat
- Provide storm water storage protection

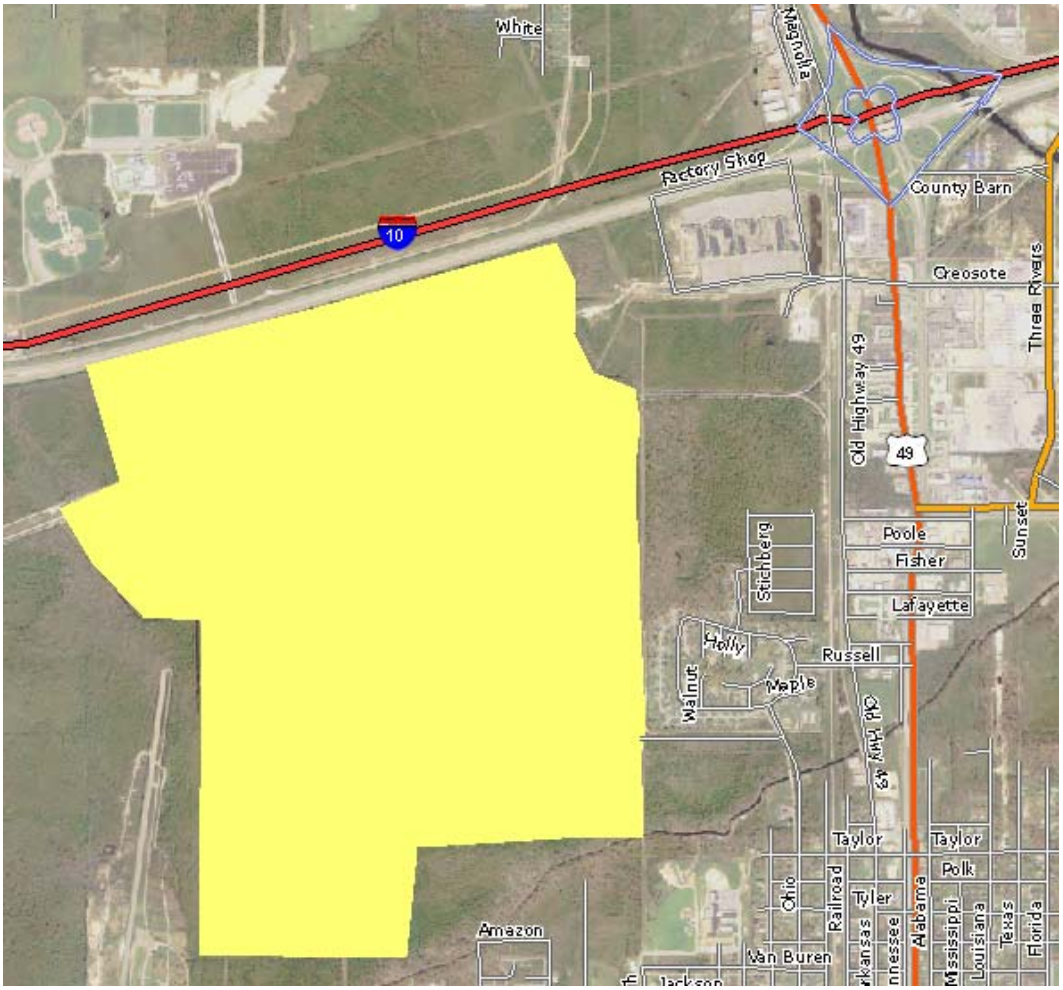

Figure 6.7-1. Location of Turkey Creek Restoration area in Planning Unit Two

6.7.1.3 Ecosystem Restoration Management Measures

Proposed restoration management measures are listed in table 6.7-1. Narrative descriptions of each management measure follow this table.

Table 6.7-1.
Ecosystem Restoration Management Measures

Management Measure	Description
No Action	No Action
1	Fill Ditches
2 a b	Maintain Vegetation By Burning By Mowing
3	Excavate and Remove Existing Roadbeds and Any Additional Fill

6.7.1.3.1 Fill Ditches (1)

This management measure must be included in all alternatives for the restoration to be successful. This measure affects the outflow of water. It measures the removal of water by ditches or drains.

6.7.1.3.2 Maintain Vegetation (2)

This management measure must be included in all alternatives for the restoration to be successful. There are two methods that will be analyzed for maintaining vegetation: (a) burning and (b) mowing. Fire benefits this ecosystem in many different ways. It creates a bare seedbed for pine seedlings and other fire dependent plants, reduces fuel loads and recycles nutrients. Periodic burning promotes early successional plants that are important to many species of wildlife indigenous to this ecosystem. Many of the plant species found in this ecosystem are fire dependent; for example, the federally endangered American Chaff seed flowers almost exclusively after a fire. It has been reduced to a fraction of its original range due to fire suppression and habitat destruction. Fire suppression is mainly due to liability issues and fear of litigation.

Mowing is a mechanical alternative that many land managers use to maintain early successional habitats. Although it is successful to some extent, it fails to provide all the necessary components that come from prescribed fire. This method also has a negative effect. Mowing requires the use of heavy equipment in sensitive areas. Tractors can create ruts in saturated soils, creating hydrologic problems and micro site conditions. Mowing can also introduce non-native species through the use of contaminated equipment. Another disadvantage of mowing is that the duff or litter layer remains on the ground, preventing seeds from reaching the bare ground needed for germination. This thick litter layer can also provide heavy fuel loads increasing the risk of wildfires during dry periods. Although mowing provides some level of habitat management in pine savannahs, it is not a substitute for prescribed fire. Mowing can maintain succession, but may inhibit other functions of the system.

6.7.1.3.3 Excavate and Remove Existing Roadbeds and Any Additional Fill (3)

This management measure must be included in all alternatives for the restoration to be successful. This measure affects the surface water storage.

6.7.1.4 Ecosystem Restoration Alternatives

These management measures were combined to create six alternatives. Each alternative requires filling ditches, maintaining vegetation growth by burning and mowing the project area in the initial year of construction as well as maintaining it by either burning every three years or mowing every year over the life of the project, and excavating and removing existing roadbeds and any additional fill. The difference between each alternative includes the number of acres restored and the method of maintaining vegetation over the life of the project.

Alternatives 1 and 2 consist of restoring the project areas north and south of the railroad: 897 acres. Alternative 1 maintains vegetation by burning once every three years. Alternative 2 maintains vegetation by mowing every year. Alternatives 3 and 4 consist of restoring only the project area south of the railroad: 689 acres. Alternative 3 maintains vegetation by burning once every three years. Alternative 4 maintains vegetation by mowing every year. Alternatives 5 and 6 consist of restoring only the project area north of the railroad: 190 acres. Alternative 5 maintains vegetation by burning once every three years. Alternative 6 maintains vegetation by mowing every year. Figure 6.7-2 shows the Turkey Creek restoration site. Table 6.7-2 displays a description of each ecosystem restoration alternative.

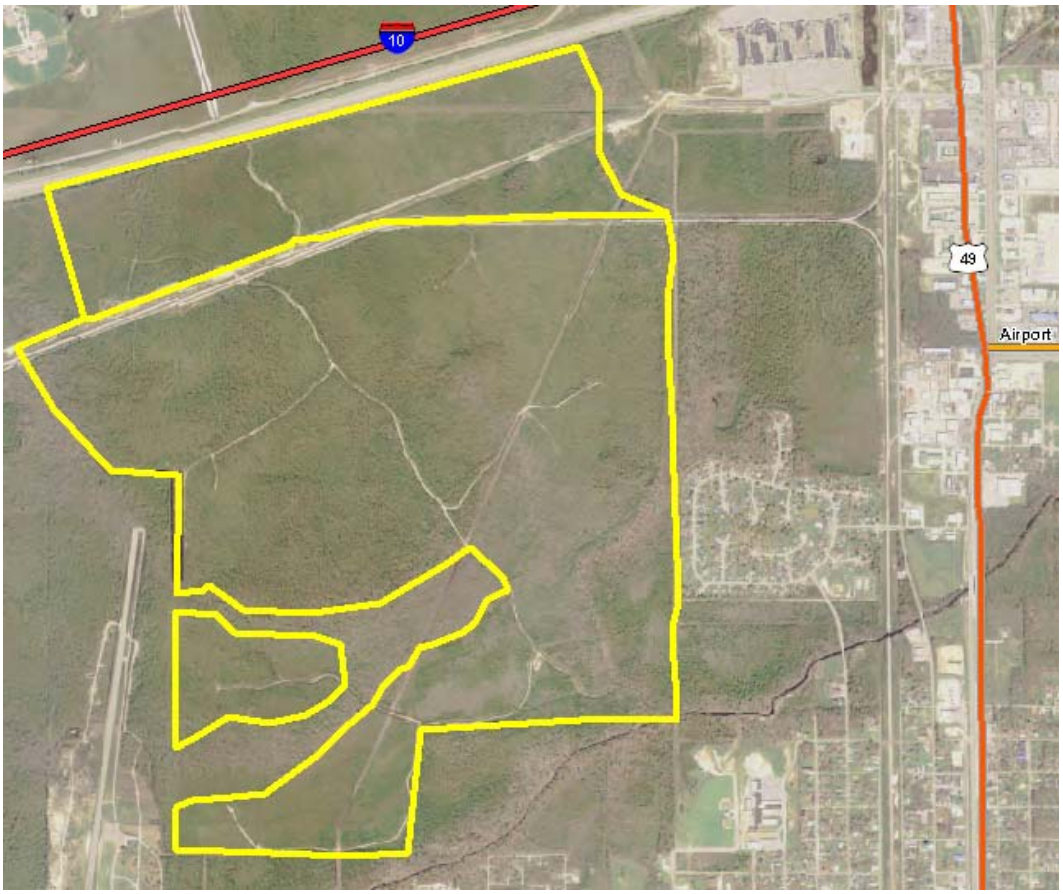

Figure 6.7-2. Turkey Creek Restoration Site

Table 6.7-2.
Ecosystem Restoration Alternatives

Alternative	Management Measures	Alternative Description
0	No Action	No Action
1	1 + 2a +3	879 Acre Restoration Maintain by Burning
2	1 + 2b + 3	879 Acre Restoration Maintain by Mowing
3	1 + 2a +3	689 Acre Restoration Maintain by Burning
4	1 + 2b + 3	689 Acre Restoration Maintain by Mowing
5	1 + 2a +3	190 Acre Restoration Maintain by Burning
6	1 + 2b + 3	190 Acre Restoration Maintain by Mowing

6.7.1.5 Benefits

In order to restore this area to a Wet Pine Savannah habitat, the higher areas will be designated as Wet Pine Savannah. These areas have depression areas within them which will enable water to flow down to the depression areas; thus, holding water. The Wet Pine Savannah habitat will be restored with Wet Pine Flatwoods, such as Pinus elliotti, Morella cerifera, Ilex glabra, Spartina patens and Panicum virgatum.

Many species of wildlife are indigenous to the Wet Pine Savannah habitat. Understory plant communities may contain wiregrass, sedges, orchids, American Chaff seed and rough-leaved loosestrife. Insectivorous plants that may be found include pitcher plants, bladderworts, venus flytrap, and sundews. Rare, threatened or endangered birds that may occur in these areas include Henslowe's sparrow, Bachman's sparrow, red-cockaded woodpecker, and Mississippi Sandhill Crane. This ecosystem may also benefit the Mississippi Gopher frog and in drier areas along ridges, the black pine snake and the gopher tortoise.

Benefits are measured in terms of Average Annual Functional Units (AAFU). The Hydrogeomorphic (HGM) approach was used to assess wetland function. A HGM assessment was performed in 2000 using the Regional Guidebook for Applying the HGM Approach to Assessing Wetland Functions of Wet Pine Flats on Mineral Soils in the Atlantic and Gulf Coastal Plains. Results from this assessment were used to establish baseline (current) conditions and, ultimately, to measure the functional unit benefits resulting from different restoration alternatives. Table 6.7-3 shows the total functional units under each alternative and the AAFU net benefit. It is assumed that functional units will remain the same under existing conditions and the no action alternative. The AAFU net benefit was calculated as the difference between the total functional units for the ecosystem restoration alternative and the total functional units for the no action alternative.

Table 6.7-3.
Summary of Benefits

Alternative	Alternative Description	Total Functional Units	AAFU Net Benefit
Existing Condition (alternatives 1-2)	Existing Condition	1,222	-
Existing Condition (alternatives 3-4)	Existing Condition	1,012	-
Existing Condition (alternatives 5-6)	Existing Condition	210	-
No Action (alternatives 1-2)	No Action	1,222	0
No Action (alternatives 3-4)	No Action	1,012	0
No Action (alternatives 5-6)	No Action	210	0
Alternative 1	879 Acre Restoration Maintain by Burning	3,268	2,046
Alternative 2	879 Acre Restoration Maintain by Mowing	2,574	1,352
Alternative 3	689 Acre Restoration Maintain by Burning	2,577	1,565
Alternative 4	689 Acre Restoration Maintain by Mowing	2,037	815
Alternative 5	190 Acre Restoration Maintain by Burning	691	481
Alternative 6	190 Acre Restoration Maintain by Mowing	537	327

6.7.1.6 Costs

A rough order magnitude (ROM) cost estimate was developed for the 879, 190, and 689 acres of restoration. It included the cost of filling ditches with 130,200, 28,100, and 102,100 cubic yards of material for $1,562,420, $337,480, and $1,224,900, respectively; burning 879, 190, and 689 acres of vegetation for $131,850, 28,480, and 103,370, respectively; mowing 879, 190, and 689 acres for $74,720, 16,140, and 58,580, respectively; removing and disposing of structures, roads and utilities for $2,601,040, $560,530, and $2,040,510, respectively; mobilizing and demobilizing for $20,000; and miscellaneous site items for $45,000. These construction costs equaled $4,435,000, $1,008,000, and $3,492,000, respectively. A contingency cost of 25% and lands and damages costs of $1,126,000, $375,000, and 777,000 were added to the construction cost. Then, Planning, Engineering and Design (PED) costs of 8% and a Construction Management cost of 6% were added for a total first cost of construction. The first cost of 879 acres of restoration is estimated at $7,600,000. The first cost of 190 acres of restoration is estimated at $1,900,000. The first cost of 689 acres of restoration is estimated at $5,900,000.

The first cost plus Interest During Construction (IDC) equals the investment cost. IDC cost of 879, 190, and 689 acres of restoration is estimated at $168,900, $41,400, and $130,200, respectively. Investment cost of 897, 190, and 689 acres of restoration is estimated at $7,800,000, $1,910,000, and $6,020,000, respectively. O&M cost of burning every three years 879, 190, and 689 acres is estimated at $3,040,000, $2,384,000, and $656,000, respectively. O&M cost of mowing every year 879, 190, and 689 acres is estimated at $5,243,000, $4,116,000, and $1,127,000, respectively. Average Annual Investment Cost (AAIC) plus Average Annual Operations and Maintenance (AAO&M) cost equals Average Annual Costs (AAC).

- For Plan 1, AAIC of $419,000 plus AAO&M of $60,000.equals an AAC of $479,000.
- For Plan 2, AAIC of $419,000 plus AAO&M of $107,000.equals an AAC of $526,000.
- For Plan 3, AAIC of $101,000 plus AAO&M of $13,000.equals an AAC of $114,000.
- For Plan 4, AAIC of $101,000 plus AAO&M of $23,000.equals an AAC of $124,000.
- For Plan 5, AAIC of $323,000 plus AAO&M of $47,000.equals an AAC of $370,000.
- For Plan 6, AAIC of $323,000 plus AAO&M of $84,000.equals an AAC of $407,000.

For each alternative, the first costs of construction, IDC, investment cost, O&M cost, AAIC, AAO&M cost and AAC are presented in table 6.7-4 at October 2007 price levels.

First cost of construction is used along with the duration of 12 months of construction and a discount rate of 4.875 percent to calculate Interest During Construction (IDC). The sum of the first cost of construction and IDC cost equals the investment cost. This cost is amortized at the FY 2007 federal discount rate of 4.875 percent over a 50-year economic period of analysis to calculate the Average Annual Investment Cost (AAIC). Average Annual O&M (AAO&M) costs for burning once every three years or mowing every year were present valued and amortized at an interest rate of 4.875 percent over a 50-year economic period of analysis. The sum of the AAIC and AAO&M cost equals the Average Annual Costs (AAC).

Table 6.7-4.
Summary of Costs by Measure for Turkey Creek

Alternative	Alternative Description	Implementation Cost (FY-08)	IDC	Investment Cost	AAIC	AAO&M	AAC
0	No Action	$0	$0	$0	$0	$0	$0
1	879 Acre Restoration Maintain by Burning	$7,636,000	$169,000	$7,804,000	$419,000	$60,000	$479,000
2	879 Acre Restoration Maintain by Mowing	$7,636,000	$169,000	$7,804,000	$419,000	$107,000	$526,000
3	689 Acre Restoration Maintain by Burning	$5,887,000	$130,000	$6,017,000	$323,000	$47,000	$370,000
4	689 Acre Restoration Maintain by Mowing	$5,887,000	$130,000	$6,017,000	$323,000	$84,000	$407,000
5	190 Acre Restoration Maintain by Burning	$1,871,000	$41,000	$1,913,000	$101,000	$13,000	$114,000
6	190 Acre Restoration Maintain by Mowing	$1,871,000	$41,000	$1,913,000	$101,000	$23,000	$124,000

Note: Numbers are rounded to the nearest thousand dollars.

6.7.2 Comparison of Alternatives

Table 6.7-5 displays all alternatives with their respective AAC and AAFU.

Table 6.7-5.
All Alternatives: AAC and AAFU

Alternative	AAC	AAFU
No Action	$0	0
1	$479,000	2,046
2	$526,000	1,352
3	$370,000	1,565
4	$407,000	815
5	$114,000	481
6	$124,000	327

Note: The AAC values are rounded to the nearest thousand dollars.

In order to determine the cost effectiveness of each alternative, the list of alternatives is reordered so that they are listed in increasing order of their outputs (AAFU). This list is shown in table 6.7-6.

To determine if an alternative is cost effective, economically inefficient alternatives must first be identified and eliminated. An economically inefficient alternative is an alternative that cost more for the same level of benefit. No alternatives are eliminated for the reason of economic inefficiency because each alternative produces a different level of benefit.

Table 6.7-6.
All Alternatives Arrayed by Increasing Output

Alternative	AAC	AAFU
No Action	$0	0
6	$124,000	327
5	$114,000	481
4	$407,000	815
2	$526,000	1,352
3	$370,000	1,565
1	$479,000	2,046

Note: The AAC values are rounded to the nearest thousand dollars.

Lastly, economically ineffective alternatives are identified and eliminated to determine which alternatives are cost effective. An economically ineffective alternative is an alternative that cost more or the same as a subsequent alternative but produces less benefit than that subsequent alternative. As shown in table 6.7-7, the three shaded alternatives, 6, 4, and 2 were eliminated because they produced less benefit at greater cost than a subsequent alternative. For example, Alternative 6 produces 327 AAFU at an AAC of $124,000 while Alternative 5 produces 481 AAFU at an AAC $114,000. Alternative 6 produces less AAFU at a greater cost than Alternative 5. Therefore, Alternative 6 is eliminated. As shown in table 6.7-8 and plotted in figure 6.7-3, the cost effective alternatives are Alternative 5 (190 acres of restoration maintained by burning), Alternative 3 (689 acres of restoration maintained by burning) and Alternative 1 (879 acres of restoration maintained by burning).

Table 6.7-7.
Elimination of Economically Ineffective Alternatives

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
6	190 Acre Restoration Maintain by Mowing	$124,000	327	No
5	190 Acre Restoration Maintain by Burning	$114,000	481	Yes
4	689 Acre Restoration Maintain by Mowing	$407,000	815	No
2	879 Acre Restoration Maintain by Mowing	$526,000	1,352	No
3	689 Acre Restoration Maintain by Burning	$370,000	1,565	Yes
1	879 Acre Restoration Maintain by Burning	$479,000	2,046	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

Table 6.7-8.
Cost Effective Alternatives for the Turkey Creek Area

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
5	190 Acre Restoration Maintain by Burning	$114,000	481	Yes
3	689 Acre Restoration Maintain by Burning	$370,000	1,565	Yes
1	879 Acre Restoration Maintain by Burning	$479,000	2,046	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

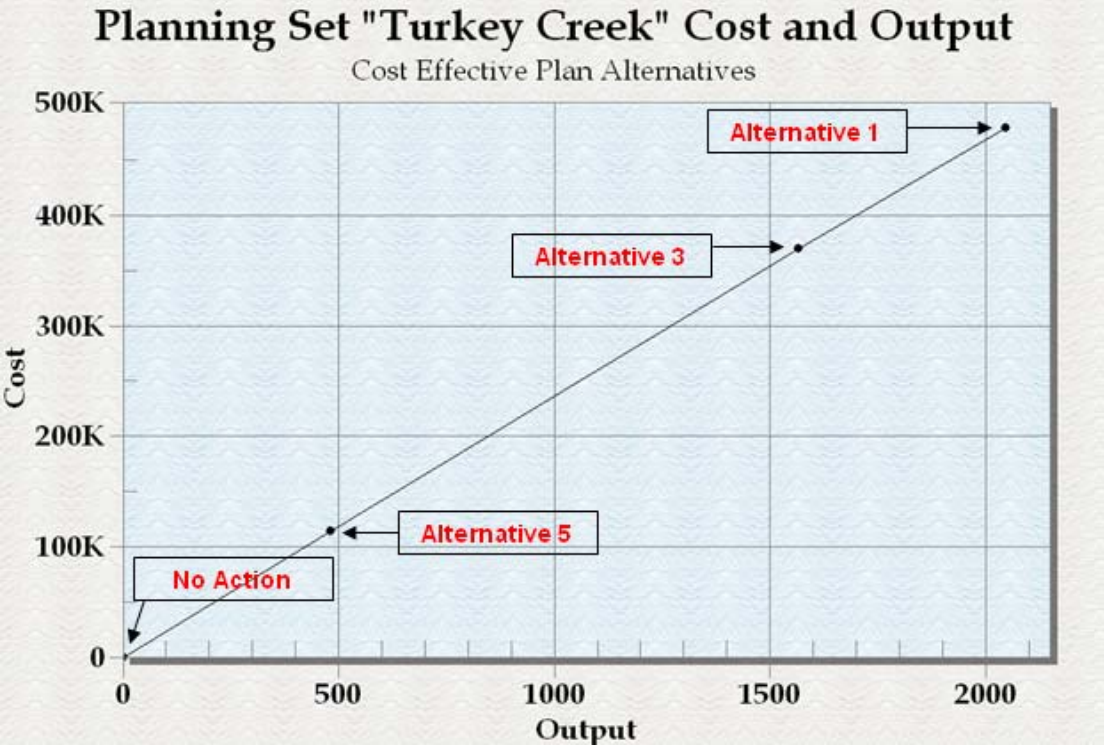

Figure 6.7-3. Display of Cost Effective Alternatives for the Turkey Creek Area

6.7.3 Regional Economic Development Benefits

6.7.3.1 Socioeconomic Impacts using the Economic Impact Forecast System

The purpose of this section is to show the economic impact of the proposed project alternatives on business (sale volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Harrison County, Mississippi. The expenditures for the alternatives are estimated to be $7,600,000 for Alternative 1, $5,900,000 for Alternative 3, $1,900,000 for Alternative 5. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $1,112,000 for Alternative 1, $872,000 for Alternative 3, and $240,000 for Alternative 5 (assuming a 50 year period of analysis and an interest rate of 4.875 percent). Tables 6.7-9 through 6.7-12 show the EIFS model inputs and outputs for the cost effect alternatives.

Table 6.7-9.
EIFS Model Implementation Inputs for Turkey Creek Ecosystem

	No Action	Alternative 1	Alternative 3	Alternative 5
Region of Influence (ROI)	Harrison County	Harrison County	Harrison County	Harrison County
Change in Local Expenditures	$0	$7,600,000	$5,900,000	$1,900,000

Based of the given inputs the outputs are as follows:

Table 6.7-10.
EIFS Model Implementation Outputs for Turkey Creek Ecosystem

	No Action	Alternative 1	Alternative 3	Alternative 5
Direct Sales Volume	$0	$7,600,000	$5,900,000	$1,900,000
Induced Sales Volume	$0	$9,500,000	$7,375,000	$2,375,000
Total Sales Volume	$0	$17,100,000	$13,275,000	$4,275,000
Direct Income	$0	$1,608,733	$1,248,884	$402,183
Induced Income	$0	$2,010,916	$1,561,106	$502,729
Total Income	$0	$3,619,648	$2,809,990	$904,912

6.8 Evaluation of Ocean Springs Area Measures

6.8.1 General

The Ocean Springs area, shown in figure 6.8-1, is located in the southwestern extent of planning unit three along the eastern shore of the Biloxi Bay. The area is denoted as planning sub-unit 22 and is depicted in the figure below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As shown in table 6.8-1, it was estimated from the field inventorying process that planning sub-unit 22 included 3,722 tax parcels, of which 3,371 contained a structure with some economic value and 351 were vacant land. Of those 3,371 parcels that contain structures, 2,995 were residential one-story, 85 were residential two-story, 5 were mobile homes, 220 were commercial, and 66 were municipal.

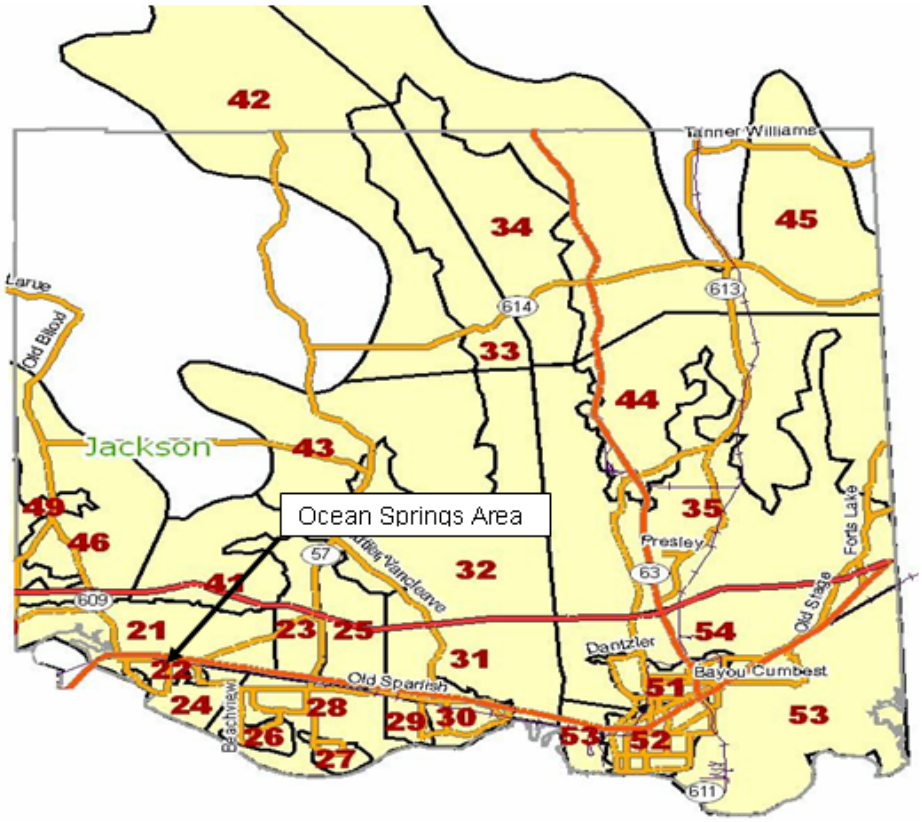

Figure 6.8-1. Ocean Springs Area – Planning Sub-unit 22

Table 6.8-1.
Pre-Hurricane Katrina Estimate of Structures for the Ocean Springs Area Planning Sub-unit 22

Asset Categories	Assets by Category
Residential	3,080
Mobile Homes	5
Commercial	220
Municipal	66
Vacant Land	351
Total Tax Parcels	**3,722**

6.8.2 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation

6.8.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4.875 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

6.8.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit three. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A – Ocean Springs 20-foot NAVD88 Ring Levee
  This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.
- Measure B – Ocean Springs 30-foot NAVD88 Ring Levee
  This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.
- Measure C – Ocean Springs Nonstructural One
  This measure includes the acquisition and flood proofing (elevate-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

- Measure D – Ocean Springs Nonstructural Two
  This measure includes the acquisition and flood proofing of structures to approximately elevation 20.0-feet NAVD88.

- Measure E – Ocean Springs Nonstructural Three
  This measure includes the acquisition and flood proofing of structures to approximately elevation 30.0-feet NAVD88.

Figure 6.8-2 shows the measures for the Ocean Springs Area (planning sub-unit 22); the red line represents the approximate footprint of the ring levees, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

Figure 6.8-2. Display of Potential Measures for the Ocean Springs Area (Planning Sub-Unit 22)

6.8.5 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December

2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.8.5.1 Existing Conditions Post-Hurricane Katrina)

The effects of Hurricane Katrina storm surge were devastating to the Ocean Springs Area. Peak water elevation in the area ranged from 20-to-21-feet NAVD88. It is estimated that between 95 and 99-percent of the structures in the area sustained significant inundation damage (fifty-percent or more). Destroyed residences and commercial structures have displaced the majority of the residences within the area. Expected redevelopment of the area is described in the following section.

6.8.5.2 Future Without-Project Conditions

Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).

Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.8-2 shows structures by asset category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there are no structures with an elevation of 1-foot or lower, and there is one structure with an elevation of 2-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Ocean Springs area.

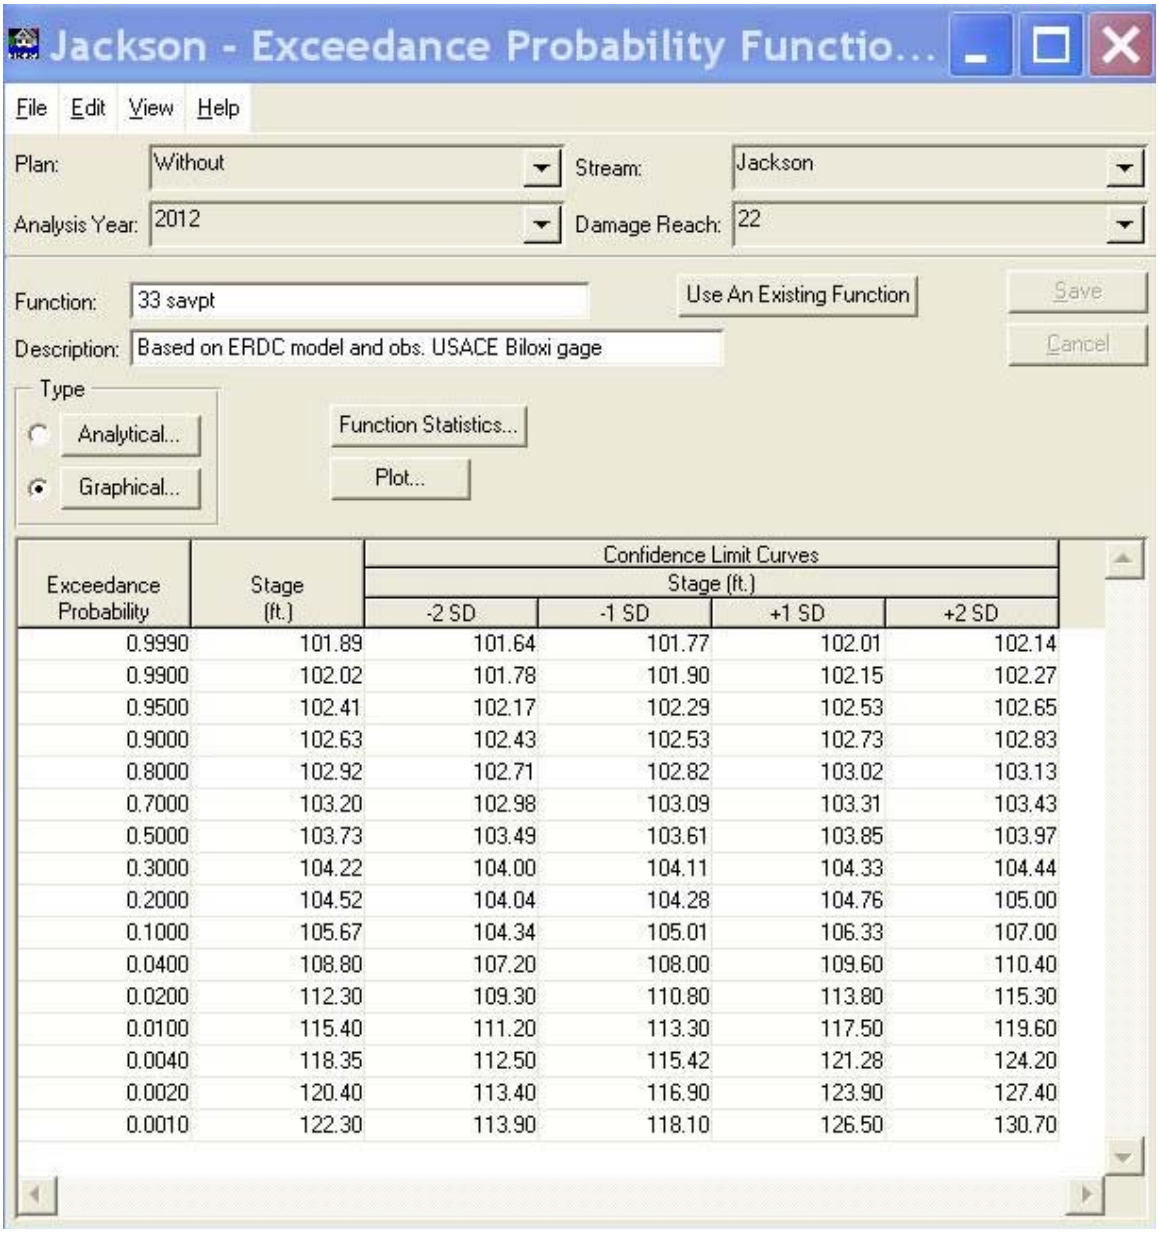

Table 6.8-2.
Cumulative Structures by Category and by Estimated First Floor Elevation Future Scenarios One, Three, and Five Applicable for Base Year and Most Likely Future Years

Estimated First Floor Elevation (NAVD88)	Residential	Mobile Homes	Commercial	Municipal	Total
1-foot	0	0	0	0	0
2-foot	1	0	0	0	1
3-foot	2	0	0	0	2
4-foot	4	0	0	0	4
5-foot	5	0	0	0	5

18-foot	387	1	11	13	412
19-foot	577	1	17	14	609
20-foot	833	1	31	18	883
21-foot	1,150	1	46	20	1,217
22-foot	1,828	4	86	36	1,954
23-foot	2,687	5	169	52	2,913
24-foot	3,038	5	214	65	3,322
25-foot	3,075	5	220	66	3,366
26-foot	3,076	5	220	66	3,367
27-foot	3,077	5	220	66	3,368
28-foot	3,078	5	220	66	3,369
29-foot	3,079	5	220	66	3,370
30-foot	3,080	5	220	66	3,371
Total	**3,080**	**5**	**220**	**66**	**3,371**

Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure; commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $1,958,000 (rounded to the nearest thousand dollars). The total number of structures in this scenario are the same as in scenario one and can be seen above in table 6.8-2. Figures 6.8-3 and 6.8-4 depict the base year and most likely future year exceedance probability functions for the Ocean Springs area (planning sub-unit 22). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.8-4 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Exceedance Probability	Stage (ft.)	Confidence Limit Curves Stage (ft.) -2 SD	-1 SD	+1 SD	+2 SD

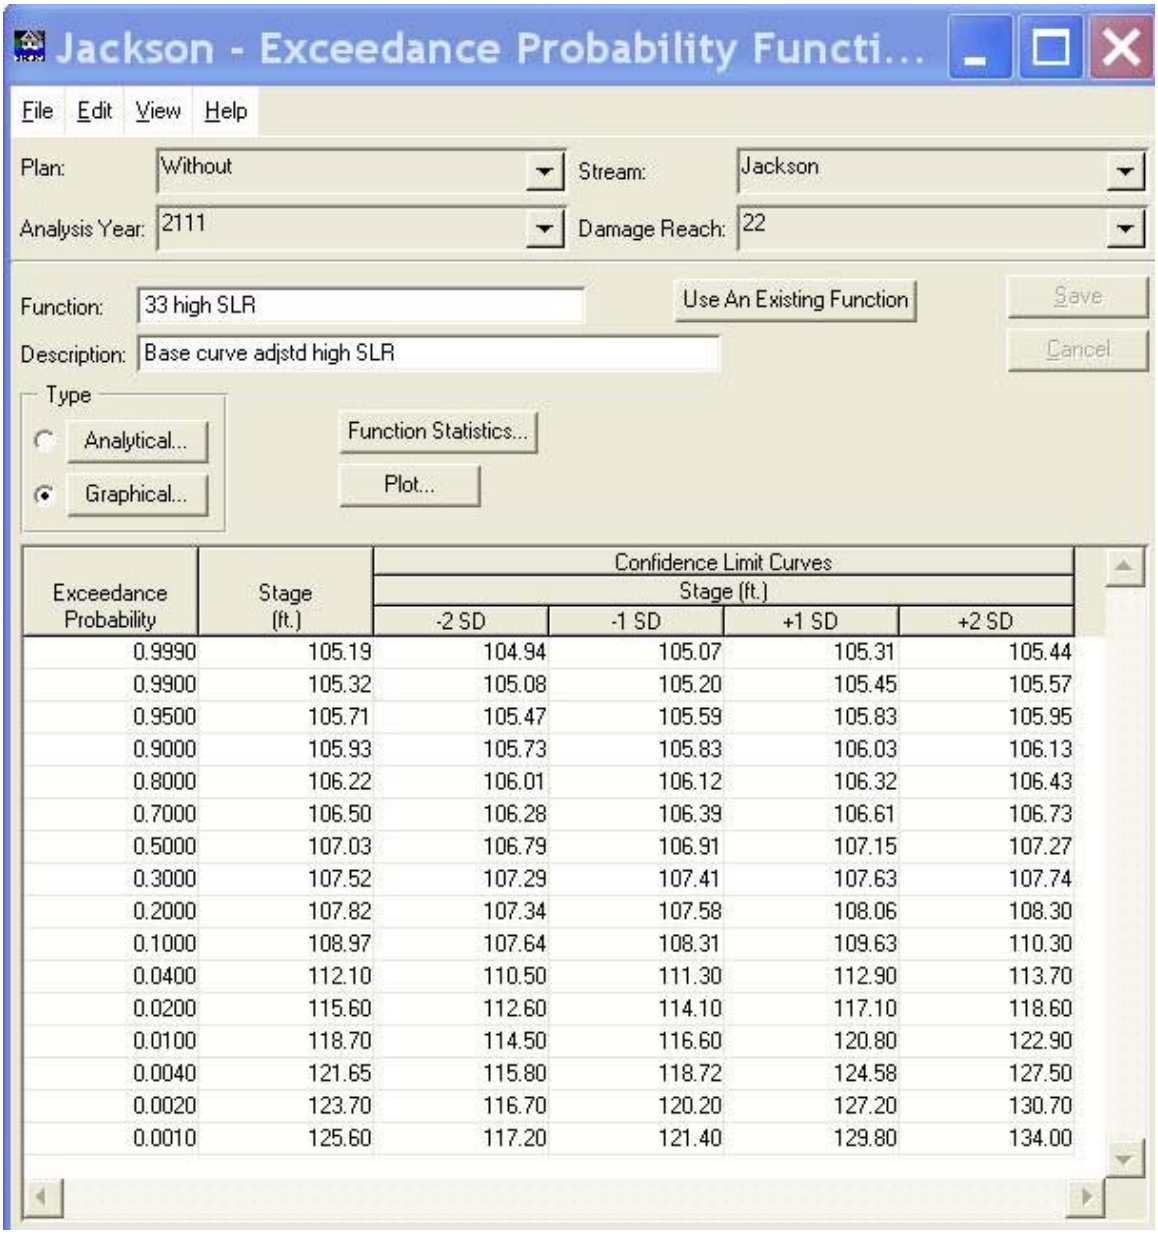
Figure 6.8-4. Future Scenario 3 Most Likely Future Year (2012) Exceedance Probability Function for the Ocean Springs Area – Includes an adjustment for relative sea level rise



Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $2,190,000 (rounded to the nearest thousand). These damages represent a approximately a ten-percent (10.2%) increase over the 2.0-feet of relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.8-2. Figures 6.8-5 and 6.8-6 depict the base year and most likely future year exceedance probability functions for the Ocean Springs area (planning sub-unit 22). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.8-6 includes an adjustment for expected relative

sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Figure 6.8-6 Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Ocean Springs Area – Includes an adjustment for relative sea level rise

6.8.5.3 Equivalent annual damages Reduced

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HECFDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures (structures to be raised in place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Ocean Springs Ring Levee at elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 150 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Ocean Springs Ring Levee at elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 488 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Ocean Springs Nonstructural One

This measure includes the acquisition of 50 parcels that include a structure and the flood proofing (raise structure in place) of 92 structures to an elevation of 16.1-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up, plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

- Measure D – Ocean Springs Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 93 parcels that include a structure and the flood proofing (raise structure in place) of 49 structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 20.0-feet NAVD88.

- Measure E – Ocean Springs Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 142 parcels that include a structure. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing

Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damages is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.8-3 summarizes the equivalent annual without-project damages, damages reduced, and residual damages by measure and by future scenario.

Table 6.8-3.
Summary of Damages by Potential Measure and by Applicable Future Scenario

Measures	Equivalent annual damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent annual damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20FT Ring Levee	$1,958,000	$1,276,000	$682,000	$2,190,000	$1,434,000	$757,000
Measure B 30FT Ring Levee	$1,958,000	$1,873,000	$85,000	$2,190,000	$2,093,000	$97,000
Measure C ABFE Nonstructural	$1,958,000	$818,000	$1,140,000	$2,190,000	$913,000	$1,277,000
Measure D 20FT Nonstructural	$1,958,000	$1,089,000	$869,000	$2,190,000	$1,235,000	$955,000
Measure E 30FT Nonstructural	$1,958,000	$1,466,000	$492,000	$2,190,000	$1,658,000	$532,000

Damages are rounded to the nearest thousand dollars.

6.8.6 Environmental Quality (EQ)

6.8.6.1 Impacts of Levee Measures

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

3) A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

4) A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.8-4 and 6.8-5 show the impacts of the Ocean Springs ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.8-4.
Wetland acres impacted by elevation 20' Ocean Springs ring levee

Reach ID	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Total
22	3.7	0.3	1.1	5.1
24	1.1	0.0	0.2	1.2
Total	**4.8**	**0.3**	**1.2**	**6.3**

Table 6.8-5.
Wetland acres impacted by elevation 30' Ocean Springs ring levee

Reach ID	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Total
22	5.2	0.4	4.7	10.3
24	2.4	0.0	2.6	5.0
Total	**7.5**	**0.4**	**7.3**	**15.2**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Ocean Springs area can be found in the Environmental Appendix.

6.8.7 Summary of Costs

Table 6.8-6 summarizes the ROM costs at an FY-08 price level by measure for the Ocean Springs area (planning sub-unit 22).

Table 6.8-6.
Summary of Costs by Measure for the Ocean Springs Area

Measures	Implementation Costs (FY-08) ($)	Capital Recovery Factor	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	0.049171225	$0	$0	$0	$0
Measure A 20FT Ring Levee	$152,100,000	0.049171225	$7,479.000	$1,414,000	N/A	$8,893,000
Measure B 30FT Ring Levee	$327,000,000	0.049171225	$16,079,000	$2,532,000	N/A	$18,611,000
Measure C ABFE Nonstructural	$59,219,000	0.049171225	$2,912,000	$10,000	N/A	$2,922,000
Measure D 20FT Nonstructural	$872,740,000	0.049171225	$42,914,000	$10,000	N/A	$42,924,000
Measure E 30FT Nonstructural	$872,740,000	0.049171225	$42,914,000	$10,000	N/A	$42,924,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns.

6.8.8 Regional Economic Development (RED)

This section summarizes how each of the measures would affect the local area of Jackson County, Mississippi. The expenditures for the measures are estimated to be $152,100,000 for the 20.0-feet NAVD88 measure, $327,000,000 for the 30.0-feet NAVD88 measure $59,219,000 for ABFE nonstructural measure, $617,965,000 for the 20.0-feet NAVD88 nonstructural measure, and $617,965,000 for the 30.0-feet NAVD88 nonstructural measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $28,757,000 for the 20.0-feet NAVD88 ring levee measure, $51,494,000 for the 30.0-feet NAVD88 ring levee measure, $203,000 for the ABFE nonstructural measure, $203,000 for the 20.0-feet NAVD88 nonstructural measure, and $203,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100 - year period of analysis and an interest rate of 4.875-percent). Tables 6.8-7 through 6.8-10 summarize the inputs and outputs of the EIFS model runs for the Ocean Springs area (planning sub-unit 22).

Table 6.8-7.
EIFS Model Implementation Costs Inputs for the Ocean Springs Area

	20-foot Ring Levee	30-foot Ring Levee	ABFE Nonstructural	20-foot Nonstructural	30-foot Nonstructural

6.9 Evaluation of Gautier Area Measures

6.9.1 General

The Gautier area, shown in Figure 6.9-1, is located in the southern portion of planning unit three along the Mississippi Sound. The area is denoted as planning sub-unit 30 and is depicted in the figure below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As demonstrated in table 6.9-1, it was estimated from the field inventorying process that planning sub-unit 30 included 3,113 tax parcels, of which 2,555 contained a structure with some economic value and 558 were vacant land. Of those 2,555 parcels that contain structures, 2,166 were residential one-story, 118 were residential two-story, 28 were mobile homes, 182 were commercial, and 61 were municipal.

6.9.2 Opportunities

The following opportunity was identified for this area:

- Hurricane storm damage reduction or remediation

6.9.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

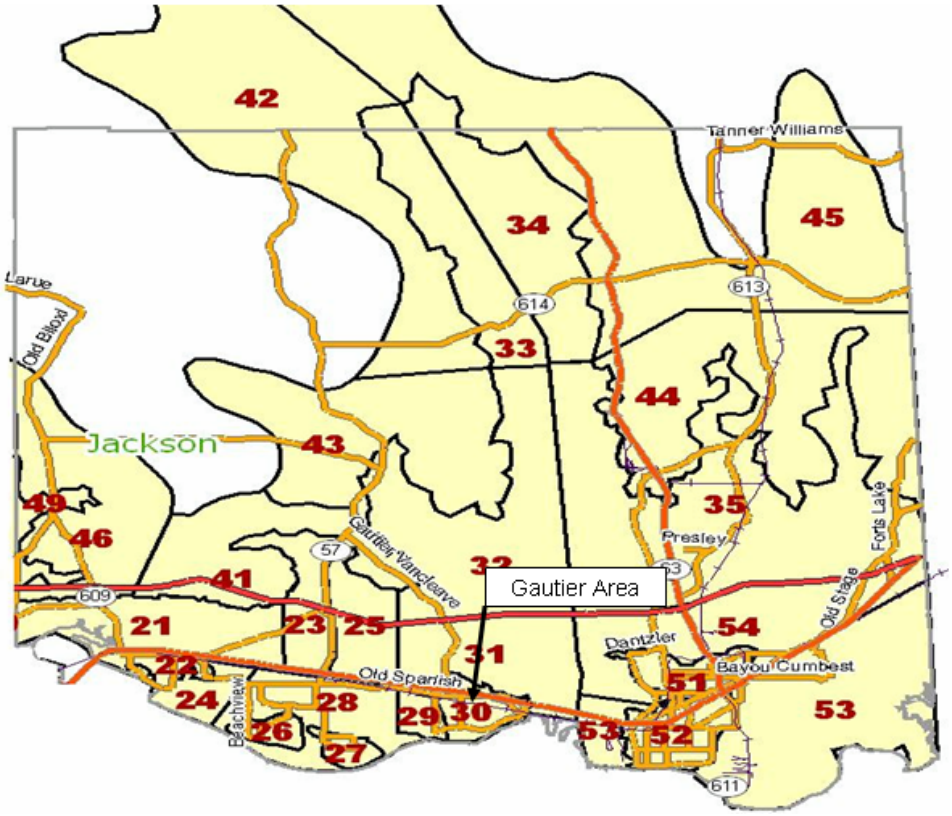

Figure 6.9-1. Gautier Area – Planning Sub-unit 30

Table 6.9-1.
Pre-Hurricane Katrina Estimate of Structures for the Gautier Area (Planning Sub-unit 30)

Asset Categories	Assets by Category
Residential	2,284
Mobile Homes	28
Commercial	182
Municipal	61
Vacant Land	558
Total Tax Parcels	**3,113**

6.9.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit three. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

Measure A – Gautier Ring Levee

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.

Measure B – Gautier Ring Levee

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.

Measure C – Gautier Nonstructural One

This measure includes the acquisition and flood proofing (elevation-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

Measure D – Gautier Nonstructural Two

This measure includes the acquisition and flood proofing of structures to approximately elevation 20-feet NAVD88.

Measure E – Gautier Nonstructural Three

This measure includes the acquisition and flood proofing of structures to approximately elevation 30-feet NAVD88.

Figure 6.9-2 shows the measures for the Gautier Area (planning sub-unit 30); the red line represents the approximate footprint of the ring levees, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

6.9.5 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.9.5.1 Existing Conditions Post-Hurricane Katrina)

The effects of Hurricane Katrina storm surge were devastating to the Gautier Area. Peak water elevation in the area ranged from 15 to 18-feet NAVD88. It is estimated that 450 of the structures in the area, mostly residential structures, and sustained significant inundation damage (fifty-percent or more). Expected redevelopment of the area is described in the following section.

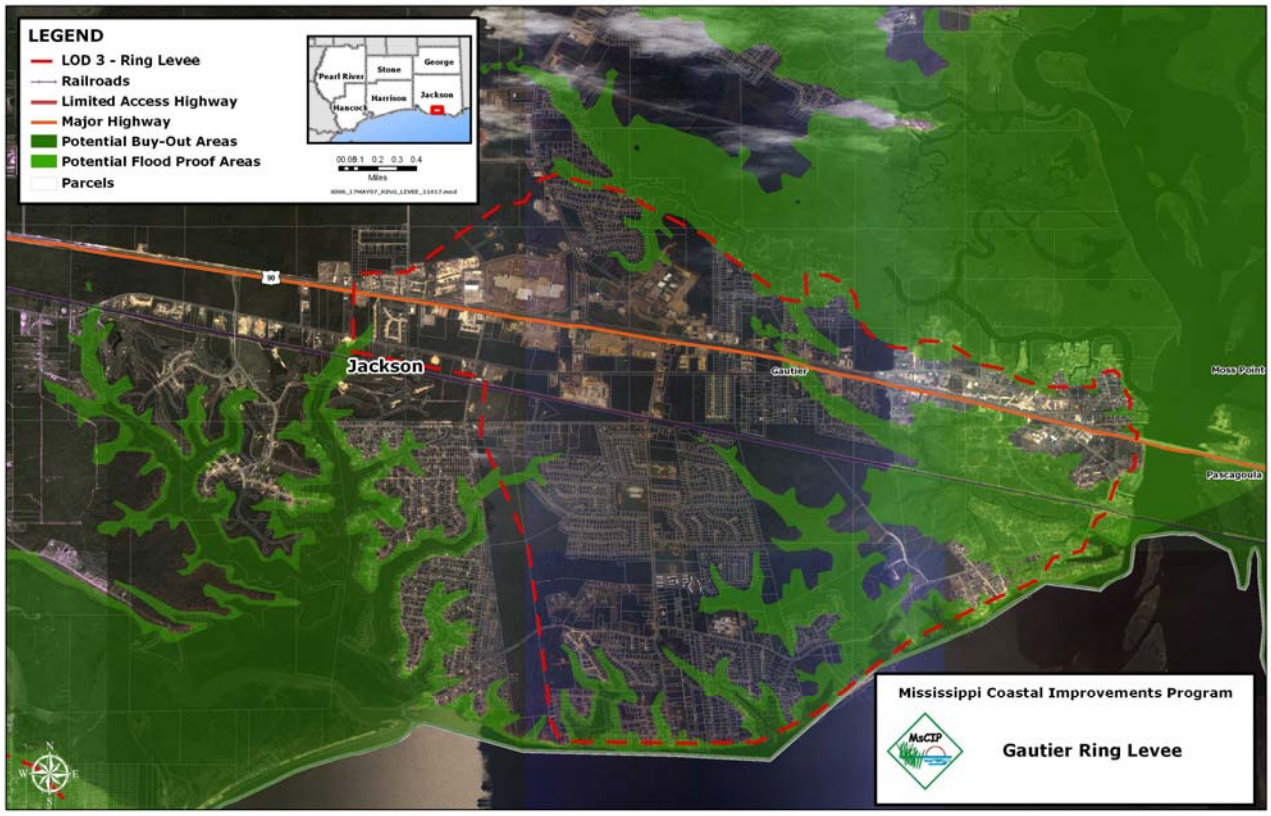

Figure 6.9-2. Display of Potential Measures for the Gautier Area (Planning Sub-Unit 30)

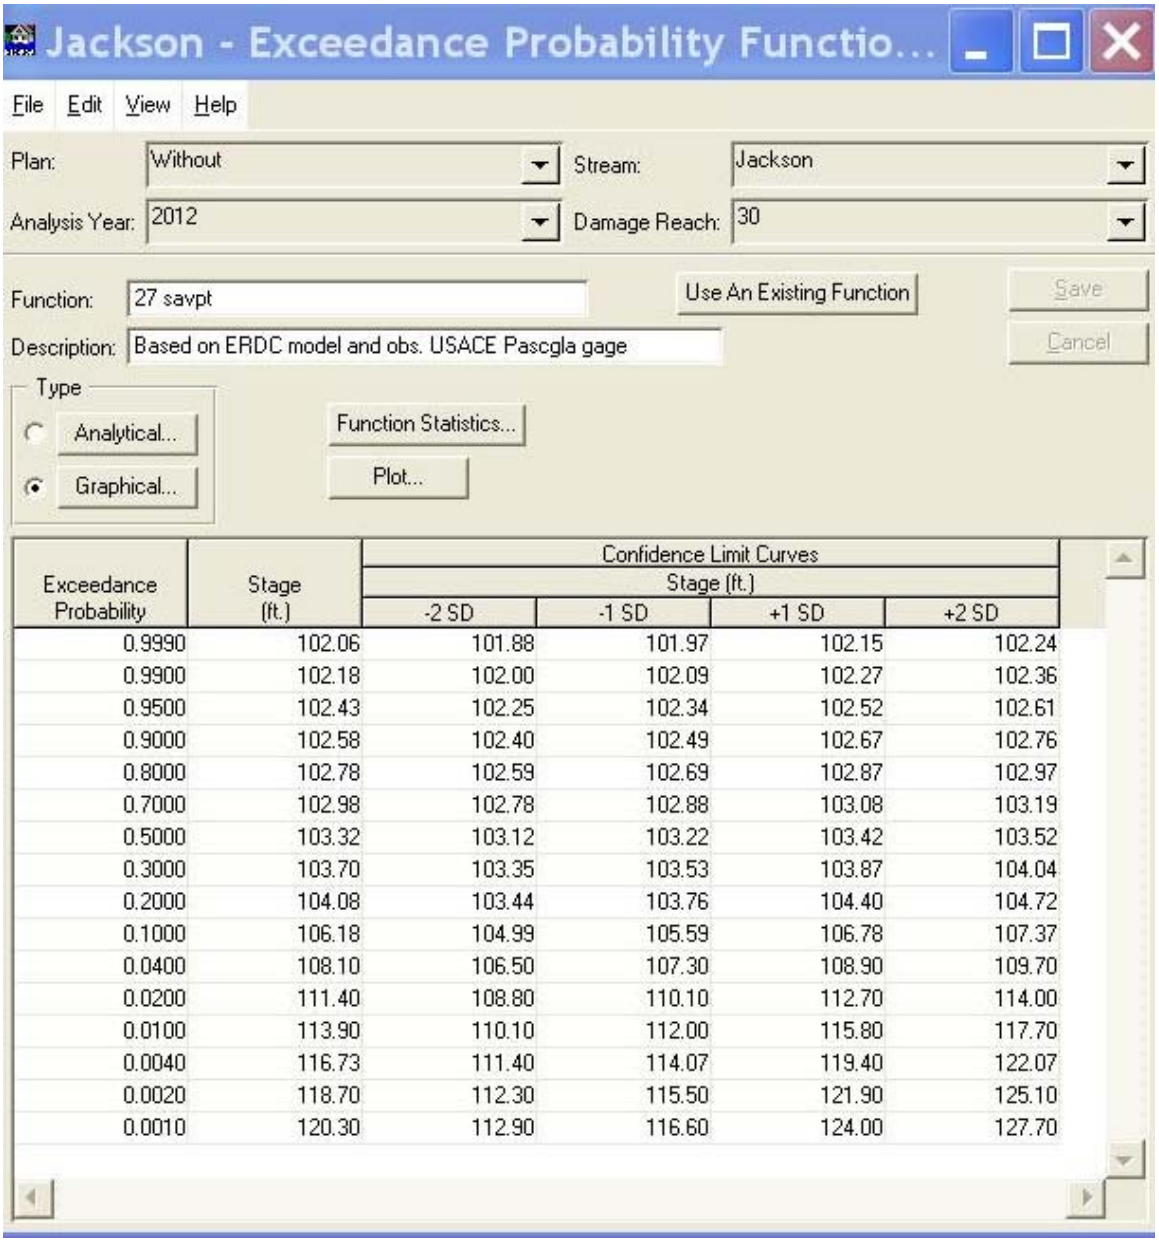
6.9.5.2 Future Without-Project Conditions

Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).



Future scenario one is the full redevelopment of assets within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.9-2 shows structures by asset category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there are two structures with an elevation of 1-foot or lower, there are five structures with an elevation of 2-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Gautier area.

Table 6.9-2.
Cumulative Structures by Category and by Estimated First Floor Elevation Future Scenarios One, Three, and Five Applicable for Base Year and Most Likely Future Years

Estimated First Floor Elevation (NAVD88)	Residential	Mobile Homes	Commercial	Municipal	Total
1-foot	2	0	0	0	2
2-foot	5	0	0	0	5
3-foot	14	0	0	0	14
4-foot	27	0	0	0	27

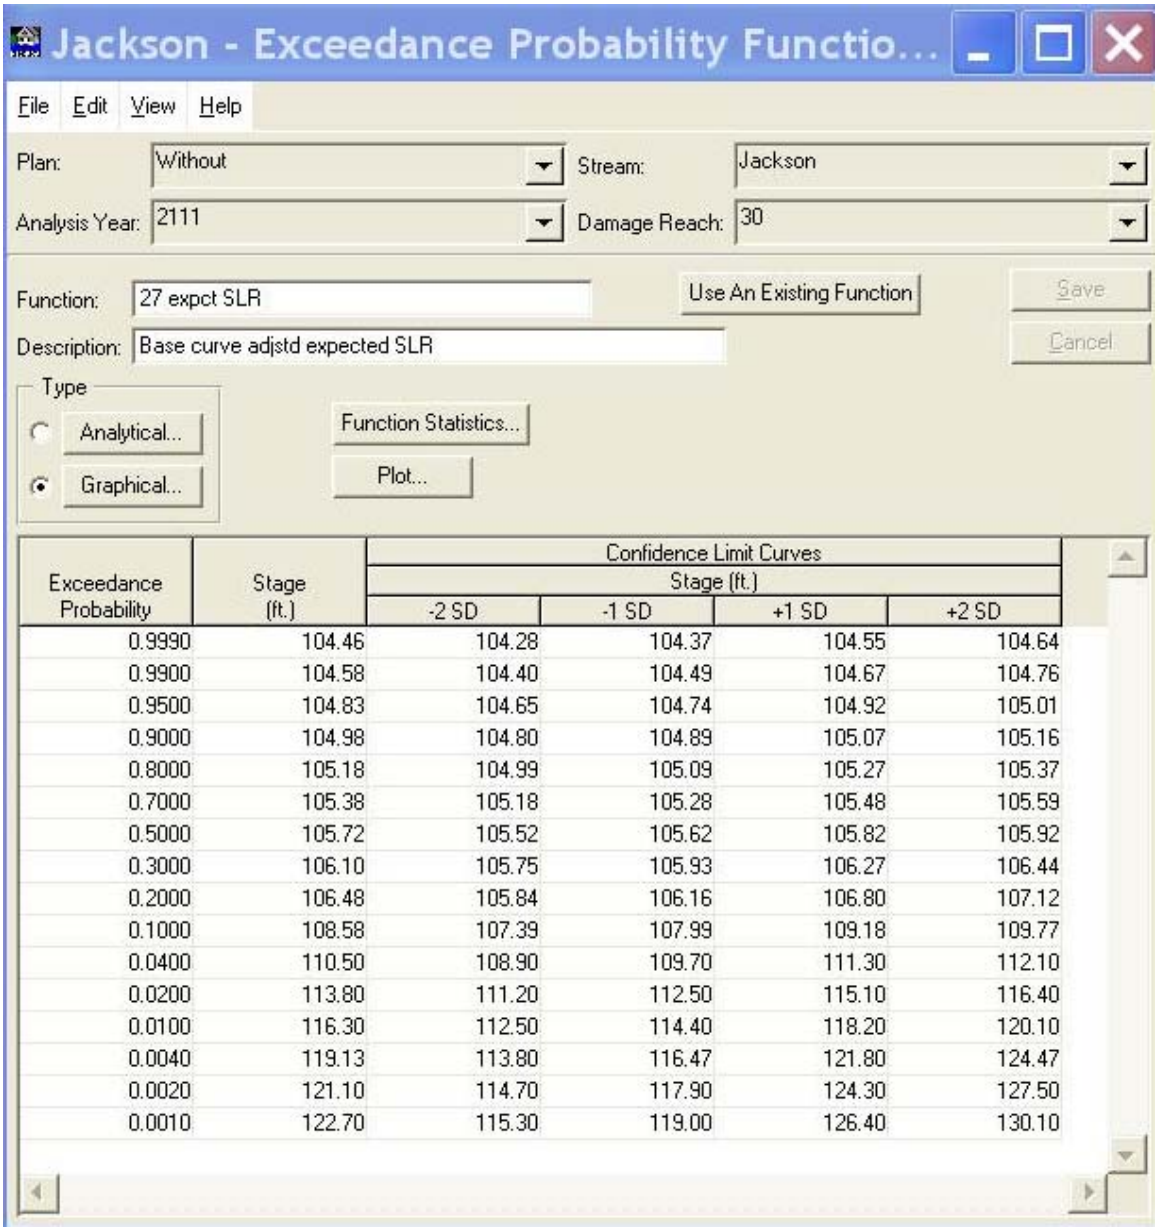
22-foot	2,279	28	178	61	2,546
23-foot	2,280	28	182	61	2,551
24-foot	2,280	28	182	61	2,551
25-foot	2,282	28	182	61	2,553
26-foot	2,282	28	182	61	2,553
27-foot	2,282	28	182	61	2,553
28-foot	2,282	28	182	61	2,553
29-foot	2,282	28	182	61	2,553
30-foot	2,282	28	182	61	2,553
31-foot	2,283	28	182	61	2,554
32-foot	2,284	28	182	61	2,555
Total	**2,284**	**28**	**182**	**61**	**2,555**



Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure; commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $5,831,000 (rounded to the nearest thousand dollars). The total number of structures in this scenario are the same as in scenario one and can be seen above in

table 6.9-2. Figures 6.9-3 and 6.9-4 depict the base year and most likely future year exceedance probability functions for the Gautier area (planning sub-unit 30). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.9-4 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Exceedance Probability	Stage (ft.)	Confidence Limit Curves Stage (ft.) -2 SD	-1 SD	+1 SD	+2 SD

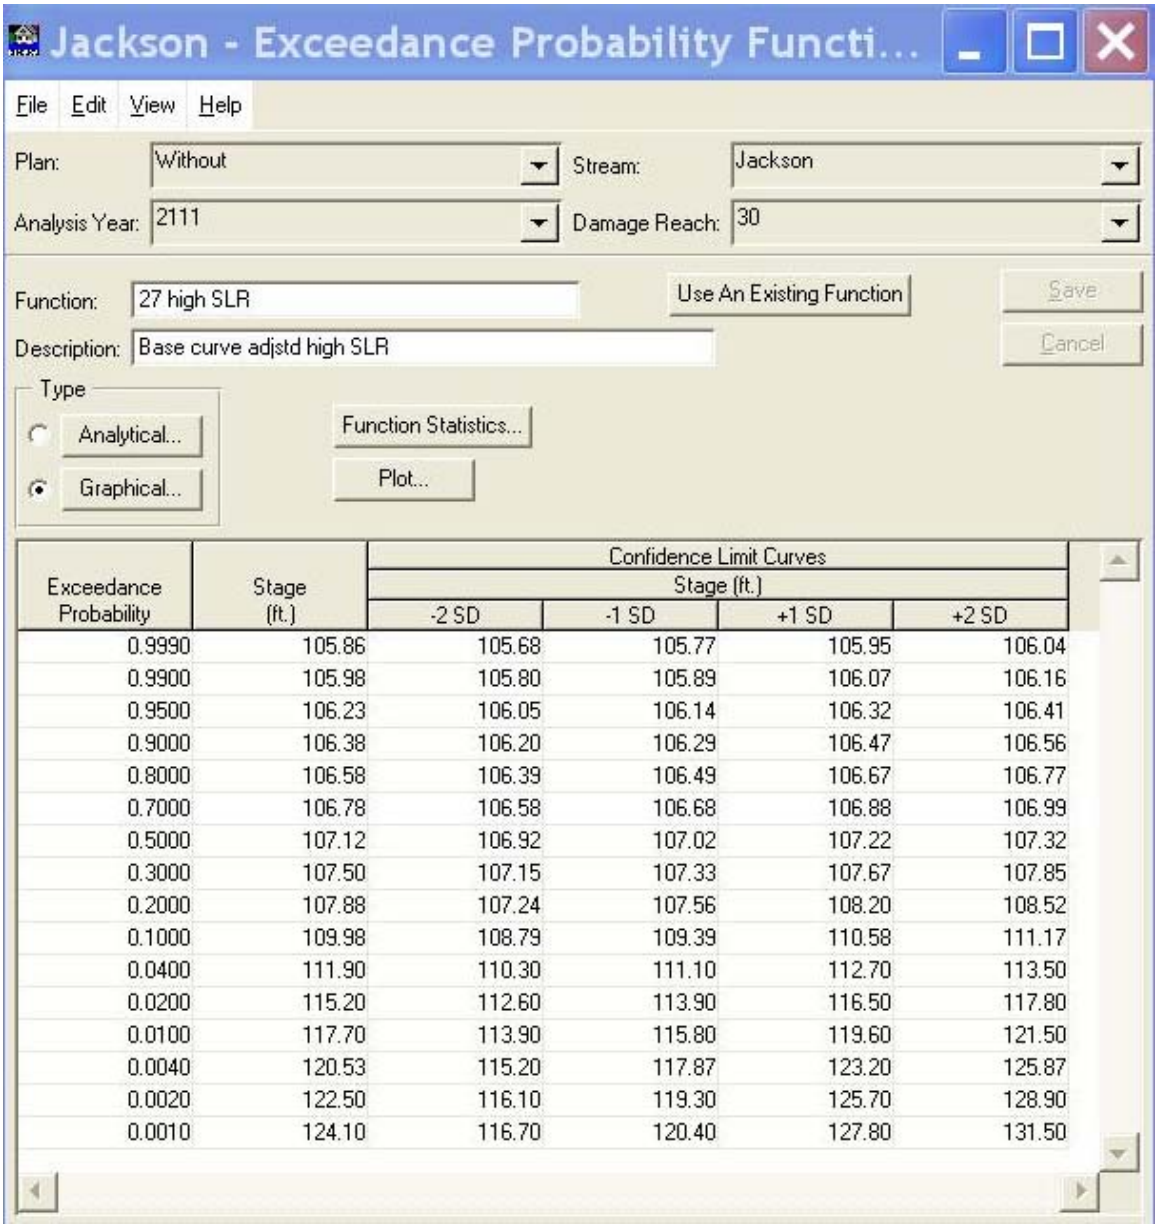
Figure 6.9-4. Future Scenario 3 Most Likely Future Year (2012) Exceedance Probability Function for the Gautier Area – Includes an adjustment for relative sea level rise



Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $6,702,000 (rounded to the nearest thousand). These damages represent approximately a ten-percent (10.2%) increase over the expected relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.9-2. Figures 6.9-5 and 6.9-6 depict the base year and most likely future year exceedance probability functions for the Gautier area (planning sub-unit 30). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.9-6 includes an adjustment for expected relative sea level

rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Figure 6.9-6. Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Gautier Area – Includes an adjustment for relative sea level rise

6.9.5.3 Equivalent Annual Damages Reduced

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HEC-FDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without-project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures (structures to be raised in place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Gautier Ring Levee at elevation 20.0-feet

This measure includes the without-project inventory less 177 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Gautier Ring Levee at elevation 30.0-feet

This measure includes the without-project inventory less 206 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Gautier ABFE Nonstructural One

This measure includes the acquisition of 66 parcels that include a structure and the flood proofing (raise structure in place) of 466 structures to an elevation of 16.1-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up, plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

- Measure D – Gautier Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 489 parcels that include a structure and the flood proofing (raise structure in place) of 44 structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 20.0-feet NAVD88.

- Measure E – Gautier Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 533 parcels that include a structure. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing

Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damages is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.9-3 summarizes the equivalent annual without-project damages, damages reduced, and residual damages by measure and by future scenario.

Table 6.9-3.
Summary of Damages by Potential Measure and by Applicable Future Scenario

Measures	Equivalent annual damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent annual damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20Ft Ring Levee	$5,831,000	$5,166,000	$665,000	$6,702,000	$5,923,000	$779,000
Measure B 30FT Ring Levee	$5,831,000	$5,800,000	$31,000	$6,702,000	$6,663,000	$39,000
Measure C ABFE Nonstructural	$5,831,000	$3,623,000	$2,208,000	$6,702,000	$3,984,000	$2,718,000
Measure D 20FT Nonstructural	$5,831,000	$ 2,457,000	$3,374,000	$6,702,000	$2,839,000	$3,863,000
Measure E 30FT Nonstructural	$5,831,000	$ 5,278,000	$553,000	$6,702,000	$6,033,000	$669,000

Damages are rounded to the nearest thousand dollars.

6.9.6 Environmental Quality (EQ)

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.9-4 and 6.9-5 show the impacts of the Gautier ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.9-4.
Wetland acres impacted by elevation 20' Gautier ring levee.

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
29	0.0	0.0	0.0	5.6	0.0	5.6
30	0.2	5.0	0.3	9.0	0.0	14.5
31	0.5	7.1	0.0	2.0	0.1	9.7
Total	**0.7**	**12.1**	**0.3**	**16.9**	**0.1**	**29.8**

Table 6.9-5.
Wetland acres impacted by elevation 30' Gautier ring levee.

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
29	0.0	0.0	0.4	9.7	0.0	10.2
30	0.3	7.2	1.2	19.8	0.0	28.5
31	1.2	10.3	0.0	6.1	0.2	17.9
Total	**1.5**	**17.5**	**1.6**	**35.7**	**0.2**	**56.5**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Gautier area can be found in the Environmental Appendix.

6.9.7 Summary of Costs

Table 6.9-6 summarizes the ROM costs at an FY-08 price level by measure for the Gautier Area (planning sub-unit 30).

Table 6.9-6.
Summary of Costs by Measure for the Gautier Area

Measures	Implementation Costs (FY-08) ($)	Capital Recovery Factor	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	0.049171225	$0	$0	$0	$0
Measure A 20Ft Ring Levee	$348,300,000	0.049171225	$17,126,000	$ 3,744,000	N/A	$20,870,000
Measure B 30FT Ring Levee	$450,100,000	0.049171225	$22,132,000	$ 4,904,000	N/A	$27,036,000
Measure C ABFE Nonstructural	$185,929,000	0.049171225	$9,142,000	$10,000	N/A	$9,152,000
Measure D 20FT Nonstructural	$783,100,000	0.049171225	$38,506,000	$10,000	N/A	$38,516,000
Measure E 30FT Nonstructural	$942,794,000	0.049171225	$46,358,000	$10,000	N/A	$46,368,000

6.9.8 Regional Economic Development (RED)

The purpose of this analysis is to determine the economic impact of the proposed project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Jackson County, Mississippi. The expenditures for the measures are estimated to be $348,300,000 for the 20.0-feet NAVD88 measure, $450,100,000 for the 30.0-feet NAVD88 measure $185,929,000 for the ABFE nonstructural measure, $783,100,000 for the 20.0-feet NAVD88 nonstructural measure, and $783,100,000 for the 30.0-feet NAVD88 nonstructural measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $76,142,000 for the 20.0-feet NAVD88 ring levee measure, $99,733,000 for the 30.0-feet NAVD88 ring levee measure, $203,000 for the ABFE nonstructural measure, $203,000 for the 20.0-feet NAVD88 nonstructural measure, and $203,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100- year period of analysis and an interest rate of 4.875-percent). The following tables 6.9-7 through 6.9-10 summarize the EIFS inputs and outputs for the Gautier area.

Table 6.9-7.
EIFS Model Construction Costs Inputs for the Gautier Area

6.10 Evaluation of Gulf Park Estates Area Measures

6.10.1 General

The Gulf Park Estates area is located in the southern portion of planning unit three along the Mississippi Sound. The area is denoted as planning sub-unit 26 and is depicted in the figure 6.10-1, shown below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As shown in table 6.10-1, it was estimated from the field inventorying process that planning sub-unit 26 included 2,391 tax parcels, of which 1,782 contained a structure with some economic value and 609 were vacant land. Of those 1,782 parcels that contain structures, 1,663 were residential one-story, 0 were residential two-story, 95 were mobile homes, 22 were commercial, and 2 were municipal.

6.10.2 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation

6.10.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4.875 percent was used in estimating average annual benefits and costs.
- Price levels are FY-08, unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

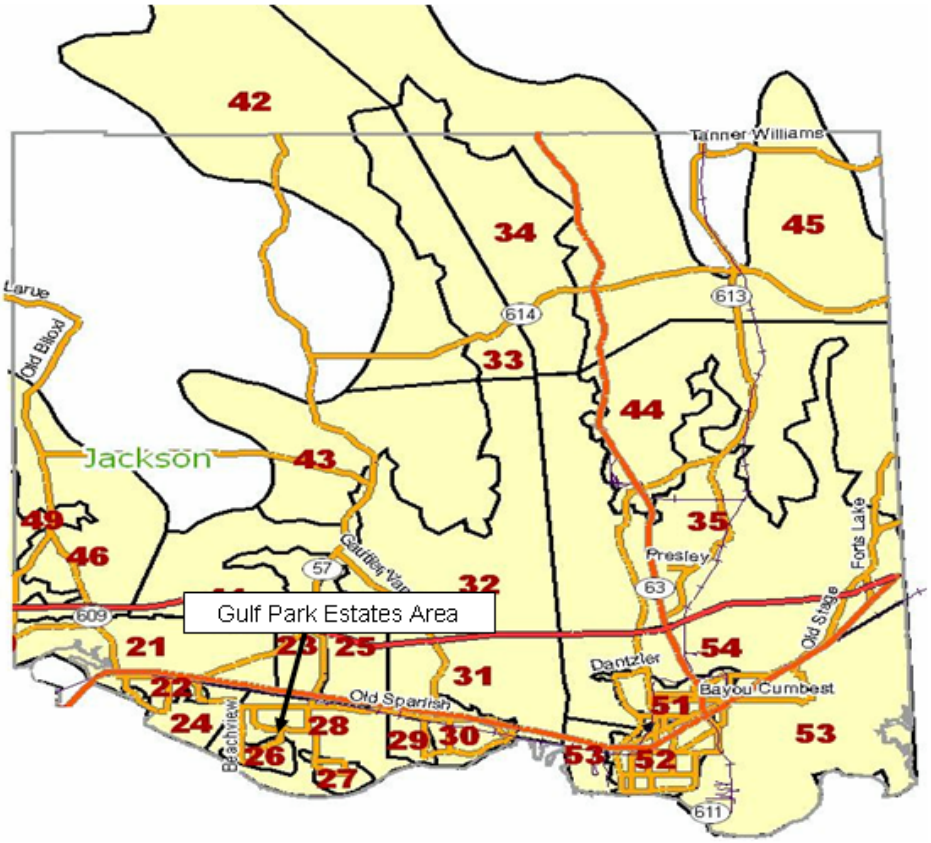

Figure 6.10-1. Gulf Park Estates Area – Planning sub-unit 26

Table 6.10-1.
Pre-Hurricane Katrina Estimate of Structures for the Gulf Park Estates Area Planning Sub-unit 26

Asset Categories	Assets by Category
Residential	1,663
Mobile Homes	95
Commercial	22
Municipal	2
Vacant Land	609
Total Tax Parcels	**2,391**

6.10.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit three. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A – Gulf Park Estates Ring Levee A

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.

- Measure B – Gulf Park Estates Ring Levee B

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.

- Measure C – Gulf Park Estates Ring Levee C

This measure would include a ring levee at 20-feet NAVD88 on an alternate footprint from Measure A and the acquisition of structures and parcels that would have been included in measure A but are not within the alternate footprint.

- Measure D – Gulf Park Estates Ring Levee D

This measure would include a ring levee at 30-feet NAVD88 on an alternate footprint from Measure B and the acquisition of structures and parcels that would have been included in measure B but are not within the alternate footprint.

- Measure E – Gulf Park Estates Nonstructural One

This measure includes the acquisition and flood proofing (elevation-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

- Measure F – Gulf Park Estates Nonstructural Two

This measure includes the acquisition and flood proofing of structures to approximately elevation 20-feet NAVD88.

- Measure G – Gulf Park Estates Nonstructural Three

This measure includes the acquisition of structures to approximately elevation 30-feet NAVD88.

Figure 6.10-2 shows the measures for the Gulf Park Estates Area (planning sub-unit 26); the red line represents the approximate footprint of the ring levees A and B, the green line represents the approximate footprint of the ring levees C and D, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

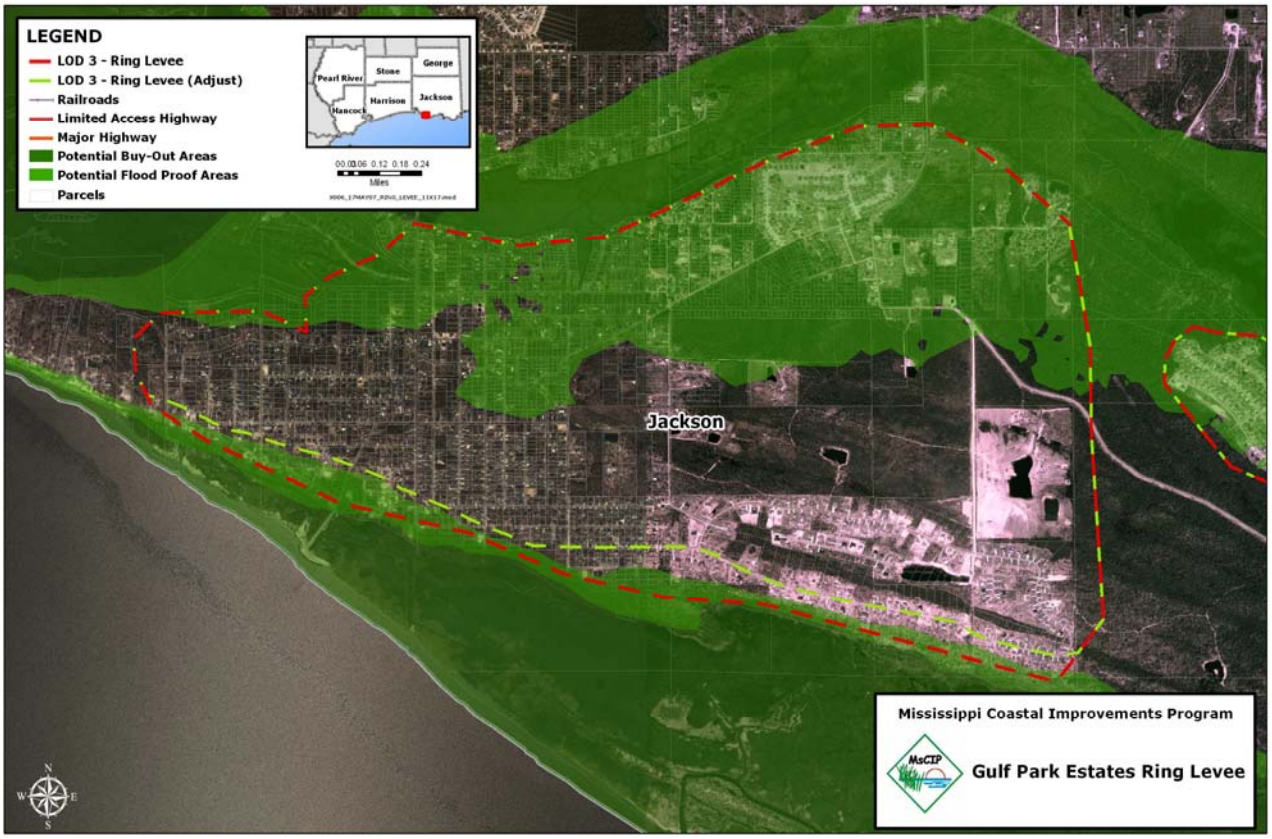

Figure 6.10-2. Display of Potential Measures for the Gulf Park Estates Area (Planning Sub-Unit 26)

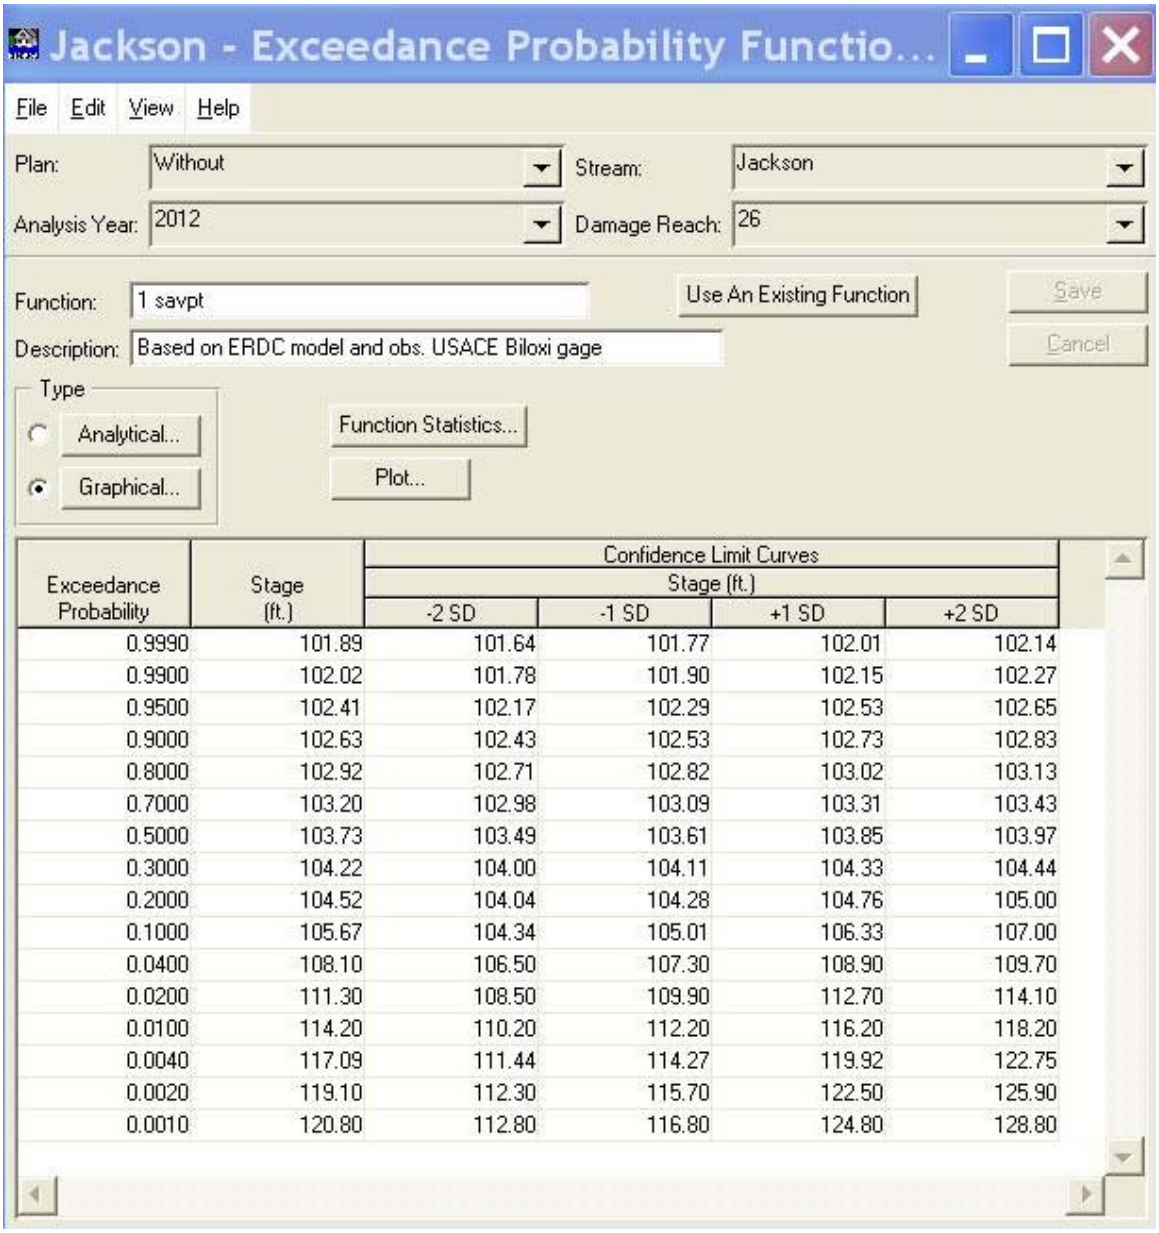
6.10.5 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.10.5.1 Existing Conditions Post-Hurricane Katrina)

The effects of Hurricane Katrina storm surge were devastating to the Gulf Park Estates Area. Peak water elevation in the area ranged from 19-to-20-feet NAVD88. It is estimated that 840 structures in the area, mostly residential, sustained significant inundation damage (fifty-percent or more). Expected redevelopment of the area is described in the following section.

6.10.5.2 Future Without-Project Conditions



Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures was evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).

Future scenario one is the full redevelopment of assets within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.10-2 shows structures by asset category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there are two structures with an elevation of 3-foot elevation or lower, there are six structures with an elevation of 4-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Gulf Park Estates area.

Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure; commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $6,273,000 (rounded to the nearest thousand dollars). The total number of structures in this scenario are the same as in scenario one and can be seen above in table 6.10-2. Figures 6.10-3 and 6.10-4 depict the base year and most likely future year exceedance probability functions for the Gulf Park Estates area (planning sub-unit 26). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.10-4 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

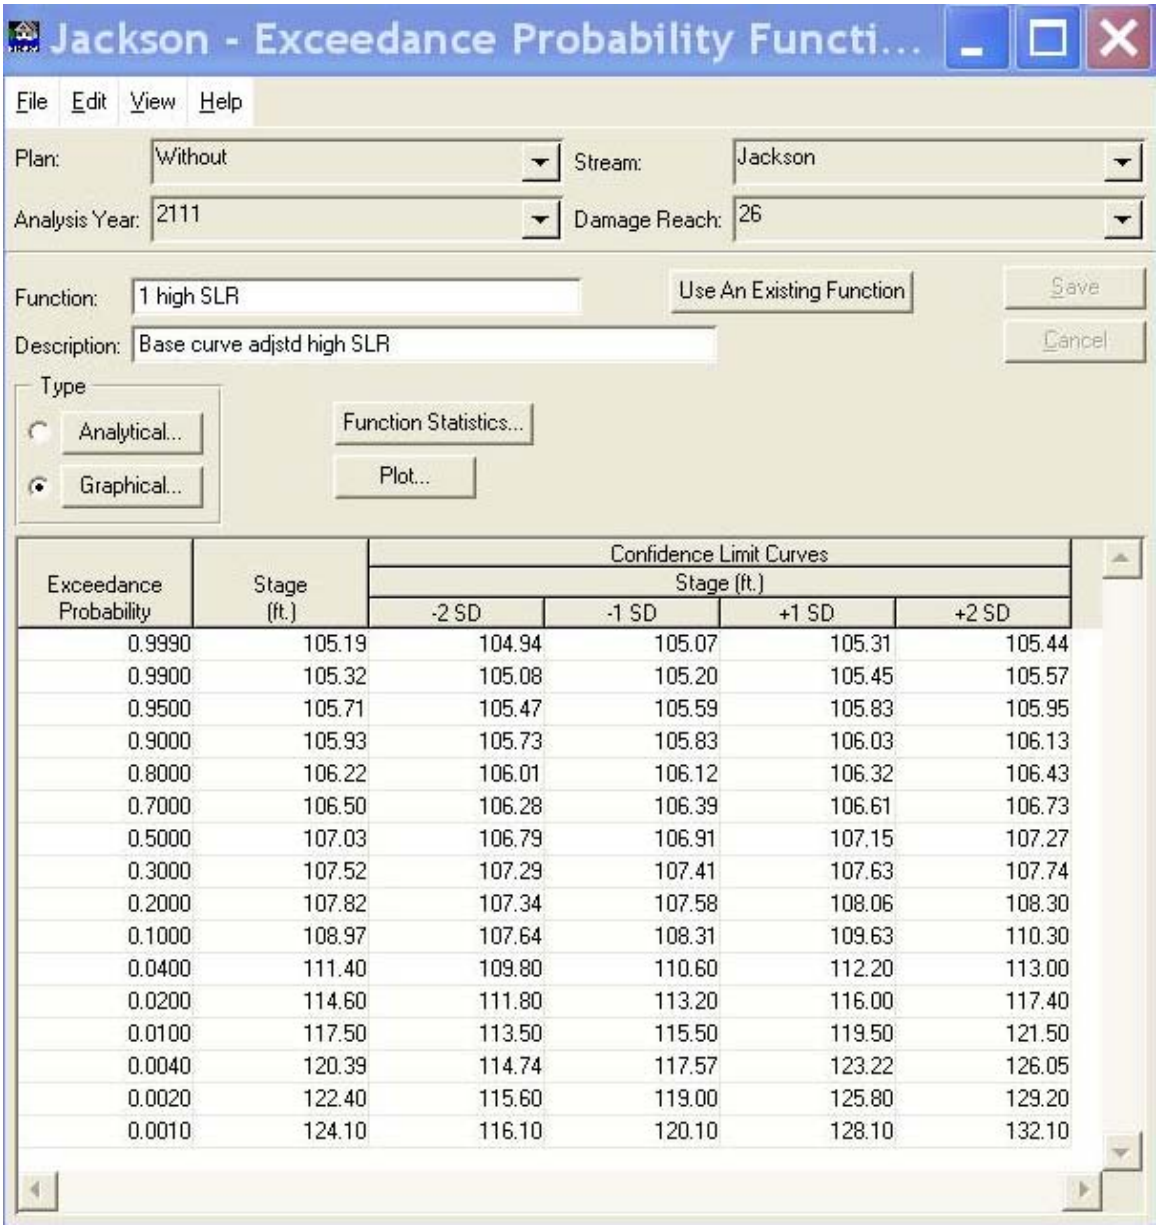
Figure 6.10-4. Future Scenario 3 Most Likely Future Year (2012) Exceedance Probability Function for the Gulf Park Estates Area – Includes an adjustment for relative sea level rise



Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $7,010,000 (rounded to the nearest thousand). These damages represent a approximately a seven-percent (6.8%) increase over the 2.0-feet relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.10-2. Figures 6.10-5 and 6.10-6 depict the base year and most likely future year exceedance probability functions for the Gulf Park Estates area (planning sub-unit 26). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.10-6 includes an adjustment for expected

relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Figure 6.10-6. Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Gulf Park Estates Area – Includes an adjustment for relative sea level rise

6.10.5.3 Equivalent annual damages Reduced and Residual Damages

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HECFDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without-project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures (structures to be raised in

place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Gulf Park Estates Ring Levee A at elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 181 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Gulf Park Estates Ring Levee B at elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 210 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Gulf Park Estates Ring Levee C at elevation 20.0-feet NAVD88

This measure would include a ring levee at 20-feet NAVD88 on an alternate footprint from Measure A and the acquisition of structures and parcels that would have been included in measure A but are not within the alternate footprint.

- Measure D – Gulf Park Estates Ring Levee D

This measure would include a ring levee at 30-feet NAVD88 on an alternate footprint from Measure B and the acquisition of structures and parcels that would have been included in measure B but are not within the alternate footprint.

- Measure E – Gulf Park Estates Nonstructural One

This measure includes the acquisition of 35 parcels that include a structure and the flood proofing (raise structure in place) of 951structures to an elevation of 18.3-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

- Measure F – Gulf Park Estates Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 939 parcels that include a structure and the flood proofing (raise structure in place) of 47structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee measures at elevation 20.0-feet NAVD88.

- Measure G – Gulf Park Estates Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 986 parcels that include a structure to an elevation of 30.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee measures at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damages is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.10-3 summarizes the equivalent annual without-project damages, damages reduced, and residual damages by measure and by future scenario.

Table 6.10-3.
Summary of Damages by Potential Measure and by Applicable Future Scenario

Measures	Equivalent annual damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent annual damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20Ft Ring Levee	$6,273,000	$5,924,000	$349,000	$7,010,000	$6,616,000	$394,000
Measure B 30FT Ring Levee	$6,273,000	$6,251,000	$23,000	$7,010,000	$6,984,000	$26,000
Measure C 20Ft Ring Levee	$6,273,000	$6,021,000	$252,000	$7,010,000	$6,762,000	$248,000
Measure D 30FT Ring Levee	$6,273,000	$6,258,000	$15,000	$7,010,000	$7,010,000	$0
Measure E ABFE Nonstructural	$6,273,000	$5,668,000	$605,000	$7,010,000	$6,327,000	$683,000
Measure F 20FT Nonstructural	$6,273,000	$5,924,000	$349,000	$7,010,000	$6,616,000	$394,000
Measure G 30FT Nonstructural	$6,273,000	$6,273,000	$0	$7,010,000	$7,010,000	$0

Damages are rounded to the nearest thousand dollars.

6.10.6 Environmental Quality (EQ)

6.10.6.1 Impacts of Ring Levee Measures

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.10-4 and 6.10-5 show the impacts of the Gulf Park Estates ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.10-4.
Wetland Acres Impacted by Elevation 20' Gulf Park Estates Ring Levee

Reach ID	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Grand Total
26	1.1	1.2	8.1	0.0	10.4
28	3.4	0.3	9.6	0.2	13.4
Total	**4.5**	**1.5**	**17.7**	**0.2**	**23.9**

Table 6.10-5.
Wetland Acres Impacted by Elevation 30' Gulf Park Estates Ring Levee.

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
26	0.0	1.5	1.9	10.6	0.0	14.0
28	0.1	5.9	0.5	14.0	0.3	20.8
Total	**0.1**	**7.4**	**2.3**	**24.6**	**0.3**	**34.8**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Gulf Park Estates area can be found in the Environmental Appendix.

6.10.7 Summary of Costs

Table 6.10-6 summarizes the ROM costs at an FY-08 price level for the Gulf Park Estates measures (planning sub-unit 26).

Table 6.10-6.
Summary of Costs by Measure for Gulf Park Estates Area

Measures	Implementation Costs (FY-08) ($)	Capital Recovery Factor	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	0.049171225	$0	$0	$0	$0
Measure A 20FT Ring Levee A	$149,200,000	0.049171225	$7,336,000	$1,499,000	N/A	$8,835,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns. Numbers are rounded to the nearest thousand.

6.10.8 Regional Economic Development (RED)

The purpose of this section is to describe the economic impact of the proposed measures would affect the local area of Jackson County, Mississippi. The expenditures for the measures are estimated to be $149,200,000 for the 20.0-feet NAVD88 ring levee measure A, $220,600,000 for the 30.0-feet NAVD88 ring levee measure B, $158,900,000 for the 20.0-feet NAVD88 ring levee measure C, $208,700,000 for the 30-foot ring levee measure D, $270,873,000 for the ABFE nonstructural measure, $294,188,000 for the 20.0-feet NAVD88 nonstructural measure, and $294,188,000 for the 30.0-feet NAVD88 nonstructural measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $30,485,000 for the 20.0-feet NAVD88 ring levee A measure, $48,890,000 for the 30.0-feet NAVD88 ring levee B measure, $26,337,000 the 20.0-feet NAVD88 ring levee C measure, $38,763,000 30.0-feet NAVD88 ring levee D measure, $203,000 for the ABFE nonstructural measure, $203,000 for the 20.0-feet NAVD88 nonstructural measure, and $203,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100- year period of analysis and an interest rate of 4.875-percent). The following tables, 6.10-7 through 6.10-10, summarize the EIFS model inputs and outputs for the Gulf Park Estates area.

Table 6.10-7.

6.11 Evaluation of Belle Fontaine Area Measures

6.11.1 General

The Belle Fontaine area is located in the southern portion of planning unit three along the Mississippi Sound. The area is denoted as planning sub-unit 27 and is depicted in the figure, 6.11-1, below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As demonstrated in Table 6.11-1, it was estimated from the field inventorying process that planning sub-unit 27 included 2,930 tax parcels, of which 1,389 contained a structure with some economic value and 1,541 were vacant land. Of those 1,389 parcels that contain structures, 1,357 were residential one-story, 0 were residential two-story, 17 were mobile homes, 12 were commercial, and 3 were municipal.

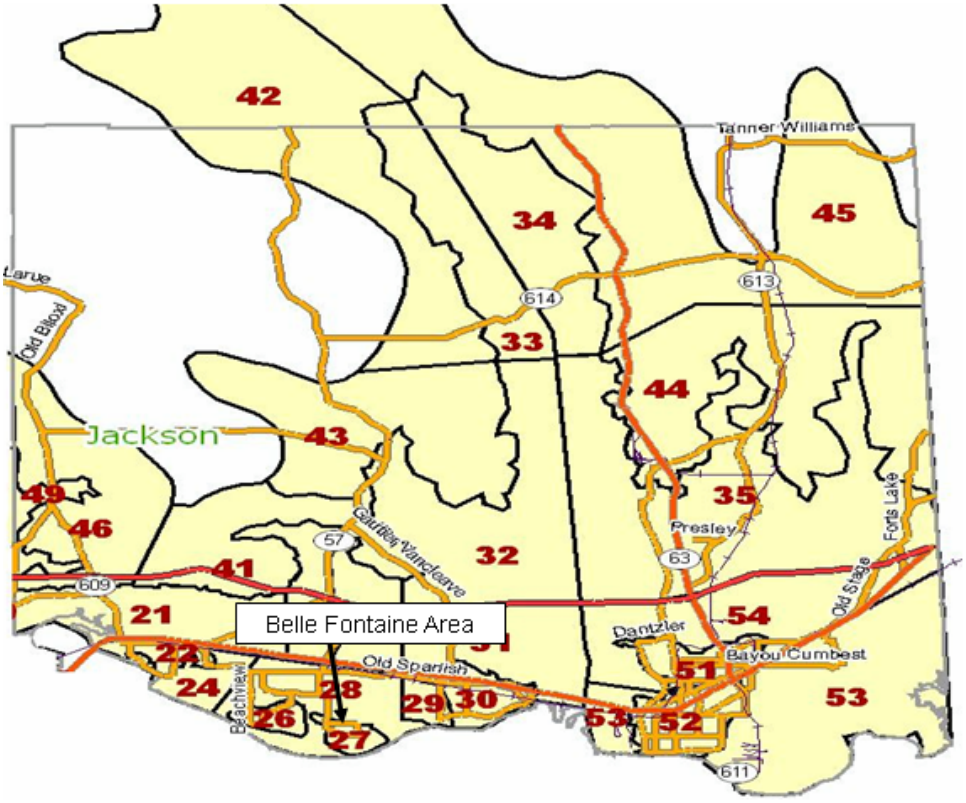

Figure 6.11-1. Belle Fontaine Area – Planning Sub-unit 27

Table 6.11-1.
Pre-Hurricane Katrina Estimate of Structures for the Belle Fontaine Area Planning Sub-unit 27

Structure Categories	Structures by Category
Residential	1,357
Mobile Homes	17
Commercial	12
Municipal	3
Vacant Land	1,541
Total Tax Parcels	**2,930**

6.11.2 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation,
- Preservation of Fish and Wildlife Habitat.

6.11.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs pertaining to the evaluation of measures for hurricane and storm damage reduction.

6.11.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit three. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A – Belle Fontaine Ring Levee A

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.

- Measure B – Belle Fontaine Ring Levee B

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.

- Measure C – Belle Fontaine Ring Levee C

This measure would include a ring levee at 20-feet NAVD88 on an alternate footprint from Measure A and the acquisition of structures and parcels that would have been included in measure A but are not within the alternate footprint.

- Measure D – Belle Fontaine Ring Levee D

This measure would include a ring levee at 30-feet NAVD88 on an alternate footprint from Measure B and the acquisition of structures and parcels that would have been included in measure B but are not within the alternate footprint.

- Measure E – Belle Fontaine Nonstructural One

This measure includes the acquisition and flood proofing (elevate-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

- Measure F – Belle Fontaine Nonstructural Two

This measure includes the acquisition and flood proofing of structures to approximately elevation 20-feet NAVD88.

- Measure G – Belle Fontaine Nonstructural Three

This measure includes the acquisition and flood proofing of structures to approximately elevation 30-feet NAVD88.

Figure 6.11-2 shows the measures for the Belle Fontaine Area (planning sub-unit 27); the red line represents the approximate footprint of the ring levee A and B measures, the green line represents the approximate footprint of the ring levee C and D measures, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

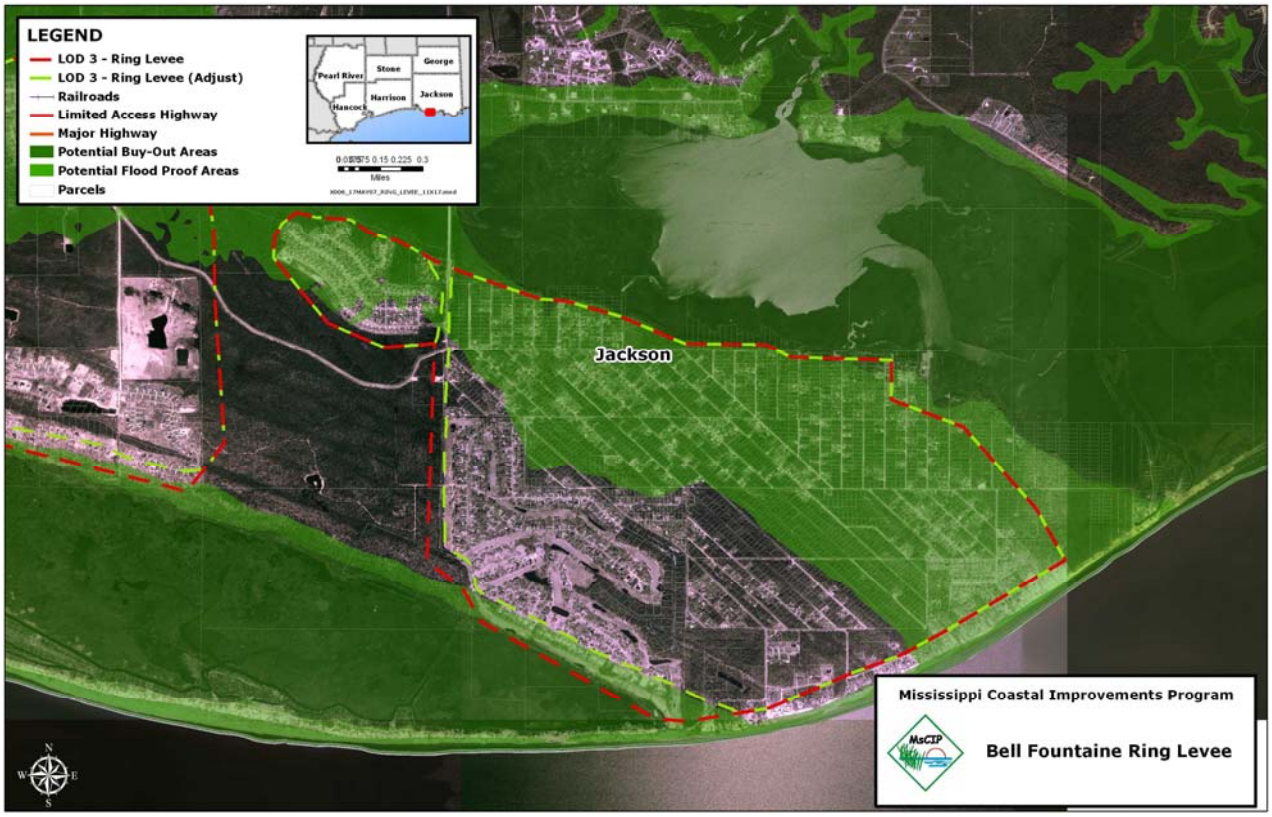

Figure 6.11-2. Display of Potential Measures for the Belle Fontaine Area (Planning Sub-unit 27)

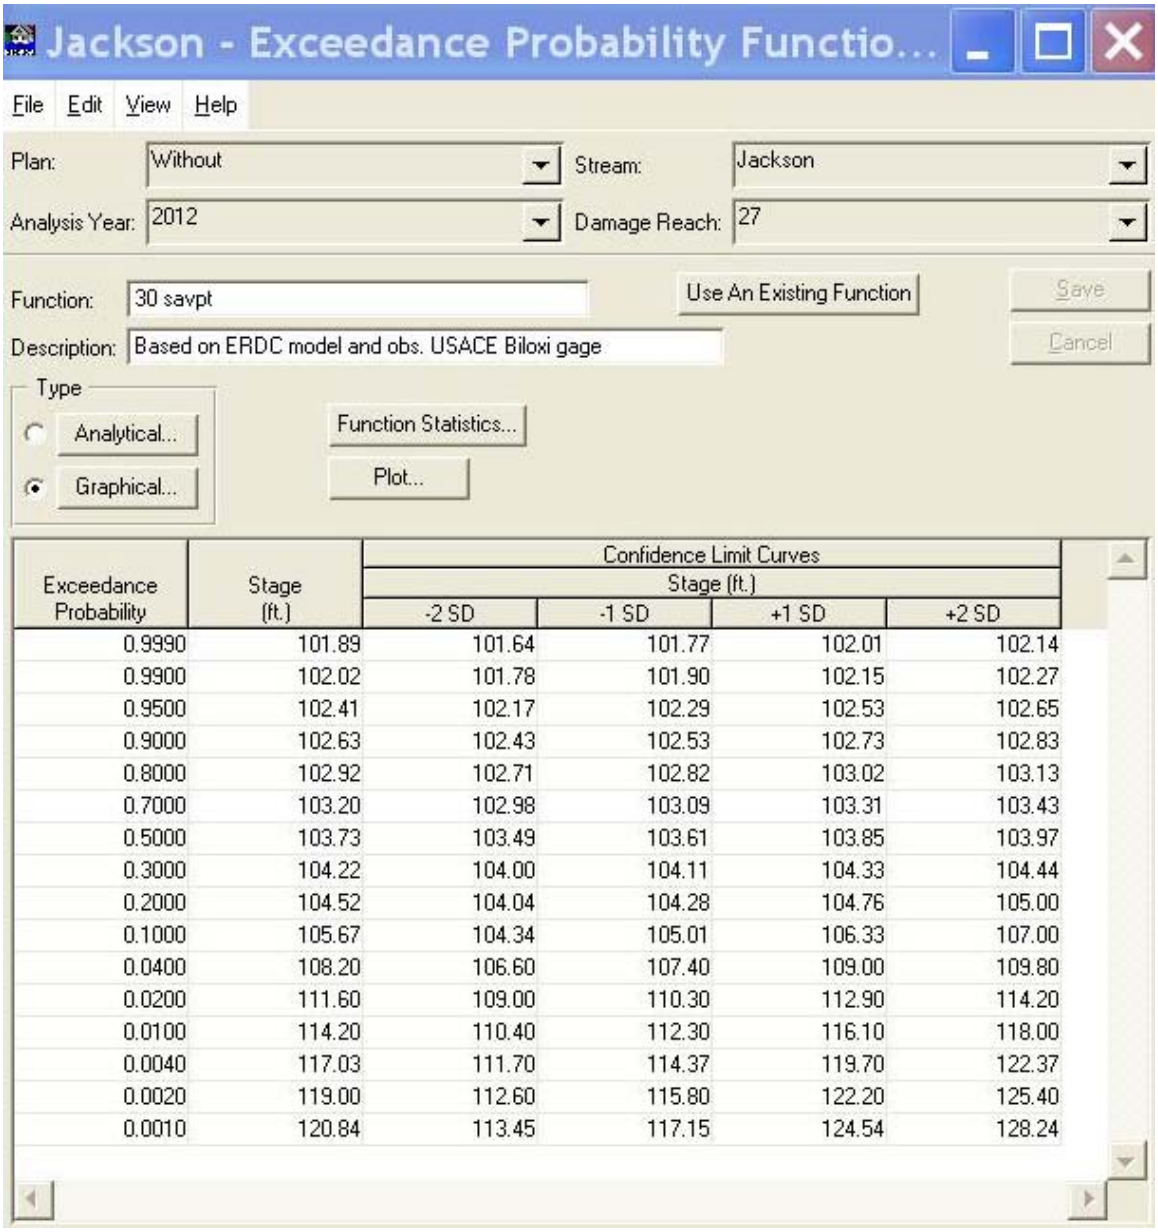
6.11.5 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.11.5.1 Existing Conditions Post-Hurricane Katrina)

The effects of Hurricane Katrina storm surge were devastating to the Belle Fontaine Area. Peak water elevation in the area was approximately19-feet NAVD88. It is estimated that 420 of the structures in the area (mostly residential) sustained significant inundation damage (fifty-percent or more). Expected redevelopment of the area is described in the following section.

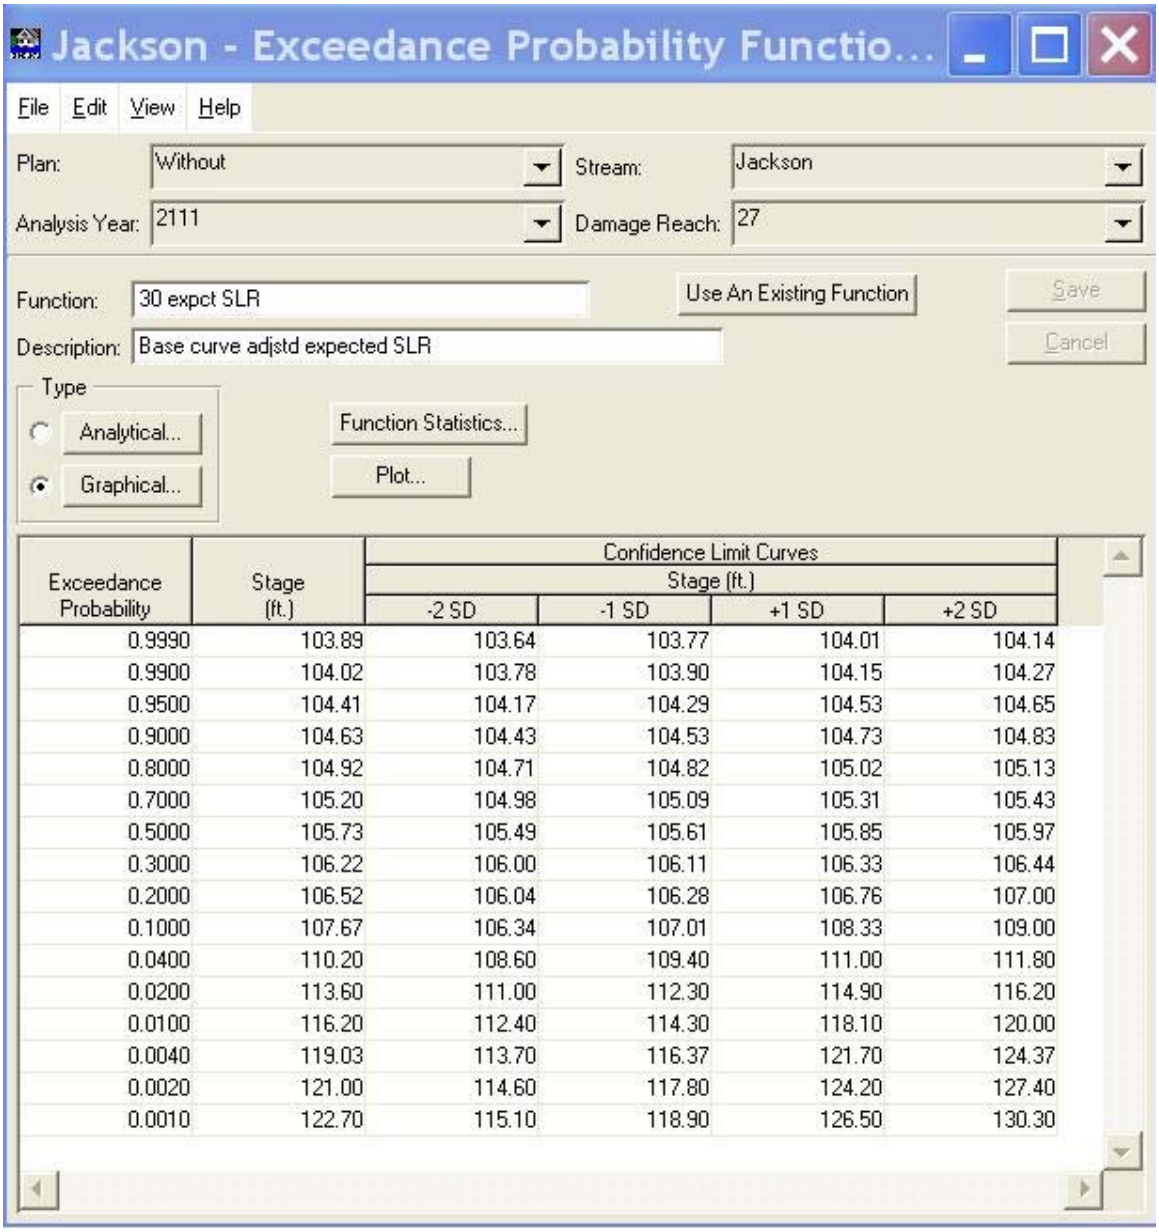
6.11.5.2 Future Without-Project Conditions



Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).

Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.11-2 shows structures by category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there are three structures with an elevation of 5-feet or lower, and there are fourteen structures with an elevation of 6-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Belle Fontaine area.

Table 6.11-2.
Cumulative Structures by Category and by Estimated First Floor Elevation Future Scenarios One, Three, and Five Applicable for Base Year and Most Likely Future Years



Estimated First Floor Elevation (NAVD88)	Residential	Mobile Homes	Commercial	Municipal	Total
1-foot	0	0	0	0	0
2-foot	0	0	0	0	0
3-foot	0	0	0	0	0
4-foot	0	0	0	0	0
5-foot	3	0	0	0	3
6-foot	14	0	0	0	14
7-foot	16	0	0	0	16
8-foot	18	0	0	0	18
9-foot	19	0	0	0	19
10-foot	28	0	0	0	28
11-foot	170	0	0	0	170
12-foot	208	0	1	0	209
13-foot	376	1	5	0	382
14-foot	707	2	7	0	716
15-foot	1,111	3	8	2	1,124
16-foot	1,166	5	9	3	1,183
17-foot	1,245	6	10	3	1,264
18-foot	1,298	7	11	3	1,319
19-foot	1,339	13	11	3	1,366
20-foot	1,346	17	12	3	1,378
21-foot	1,355	17	12	3	1,387
22-foot	1,357	17	12	3	1,389
Total	**1,357**	**17**	**12**	**3**	**1,389**

Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure; commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $2,506,000 (rounded to the nearest thousand dollars). The total number of structures in this scenario are the same as in scenario one and can be seen above in table 6.11-2. Figures 6.11-3 and 6.11-4 depict the base year and most likely future year exceedance probability functions for the Belle Fontaine area (planning sub-unit 27). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.11-4 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet.For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

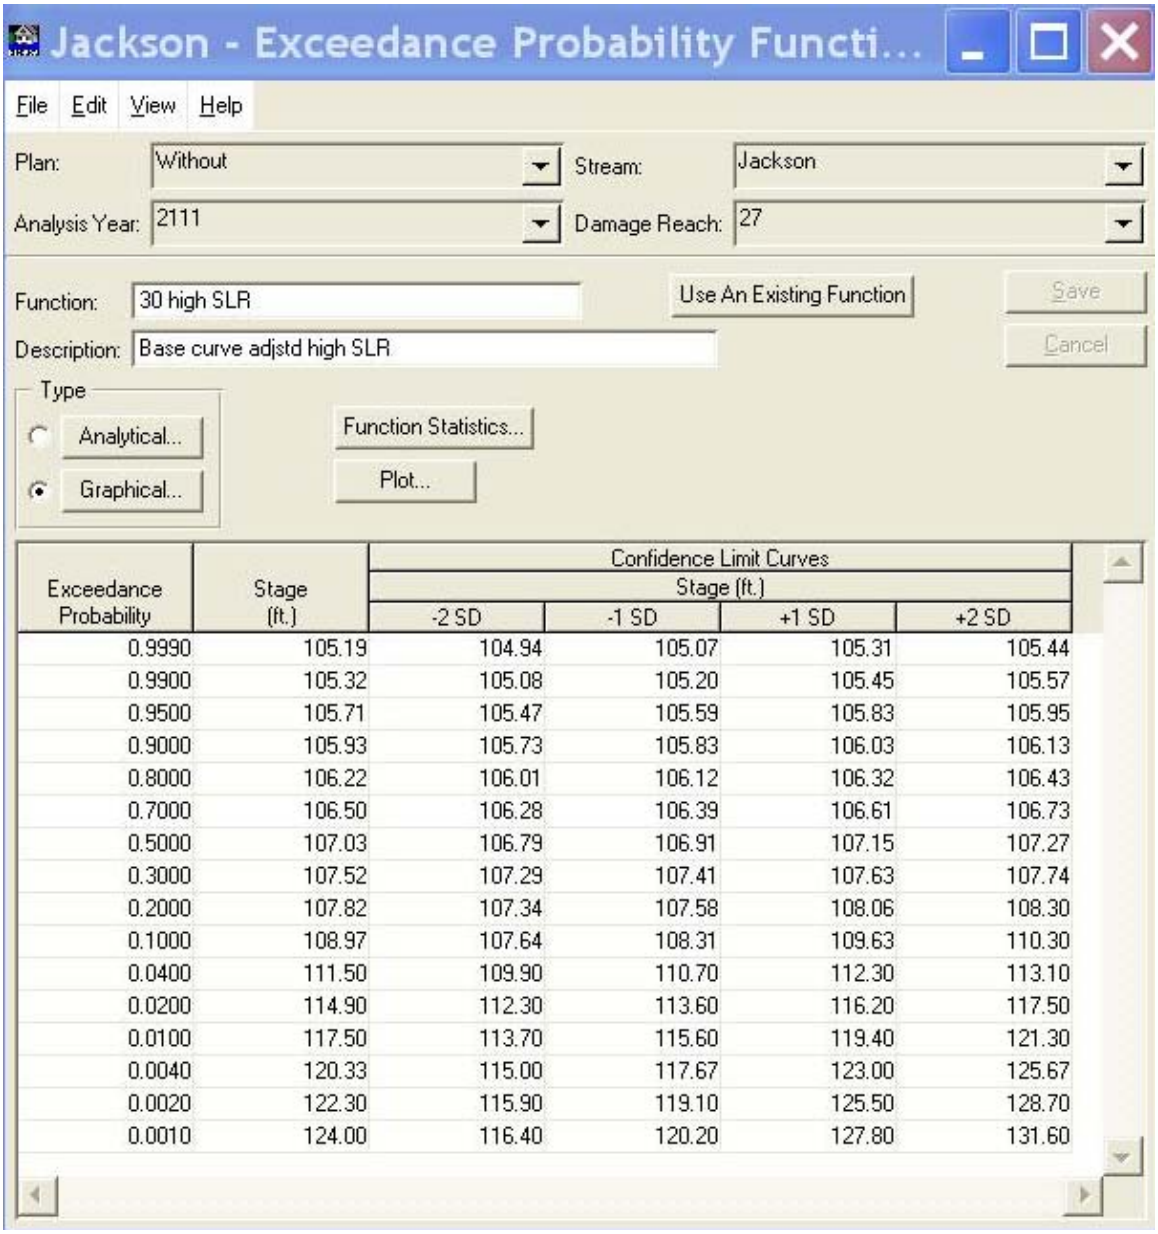
Figure 6.11-4. Future Scenario 3 Most Likely Future Year (2012) Exceedance Probability Function for the Belle Fontaine Area – Includes an adjustment for relative sea level rise



Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $2,950,000 (rounded to the nearest thousand). These damages represent approximately an eighteen-percent (17.7%) increase over the expected relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.11-2. Figures 6.11-5 and 6.11-6 depict the base year and most likely future year exceedance probability functions for the Belle Fontaine area (planning sub-unit 27). The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability function depicted in figure 6.11-6 includes an adjustment for

expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet.For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Figure 6.11-6. Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Belle Fontaine Area – Includes an adjustment for relative sea level rise

6.11.5.3 Equivalent annual damages Reduced

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HECFDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures (structures to be raised in

place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Belle Fontaine Ring Levee A at elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 101 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Belle Fontaine Ring Levee B at elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 118 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Belle Fontaine Ring Levee C at elevation 20.0-feet NAVD88

This measure would include a ring levee at 20-feet NAVD88 on an alternate footprint from Measure A and the acquisition of structures and parcels that would have been included in measure A but are not within the alternate footprint.

- Measure D – Belle Fontaine Ring Levee D

This measure would include a ring levee at 30-feet NAVD88 on an alternate footprint from Measure B and the acquisition of structures and parcels that would have been included in measure B but are not within the alternate footprint.

- Measure E – Belle Fontaine Nonstructural One

This measure includes the acquisition of 32 parcels that include a structure and the flood proofing (raise structure in place) of 1,028 structures to an elevation of 14.55-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up, plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).

- Measure F – Belle Fontaine Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 177 parcels that include a structure and the flood proofing (raise structure in place) of 883 structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee measures at elevation 20.0-feet NAVD88.

- Measure G – Belle Fontaine Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 1,060 parcels that include a structure. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing

Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levee measures at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damages is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.11-3 summarizes the without project damages, damages reduced, and residual damages by measure and by future scenario.

Table 6.11-3.
Summary of Damages by Measure

Measures	Equivalent Annual Damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent Annual Damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20FT Ring Levee A	$2,506,000	$2,235,000	$271,000	$2,950,000	$2,641,000	$309,000
Measure B 30FT Ring Levee B	$2,506,000	$2,493,000	$13,000	$2,950,000	$2,933,000	$17,000
Measure C 20FT Ring Levee C	$2,506,000	$2,350,000	$156,000	$2,950,000	$2,765,000	$185,000
Measure D 30FT Ring Levee D	$2,506,000	$2,506,000	$0	$2,950,000	$2,950,000	$0
Measure C ABFE Nonstructural	$2,506,000	$1,425,000	$1,081,000	$2,950,000	$1,652,000	$1,298,000
Measure D 20FT Nonstructural	$2,506,000	$2,235,000	$271,000	$2,950,000	$2,641,000	$309,000
Measure E 30FT Nonstructural	$2,506,000	$2,506,000	$0	$2,950,000	$2,950,000	$0

Damages are rounded to the nearest thousand dollars.

6.11.6 Environmental Quality (EQ)

6.11.6.1 Impacts of Ring Levee Measures

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.11-4 and 6.11-5 show the impacts of the Belle Fontaine ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.11-4.
Wetland Acres Impacted by Elevation 20' Belle Fontaine Ring Levee A

Reach ID	Estuarine and Marine Wetland	Freshwater Forested/ Shrub Wetland	Freshwater Pond	Total
27	4.7	14.2	0.4	19.3
28	9.5	18.0	0.2	27.6
Total	**14.2**	**32.2**	**0.5**	**46.9**

Table 6.11-5.
Wetland Acres Impacted by Elevation 30' Belle Fontaine Ring Levee B

Reach ID	Estuarine and Marine Wetland	Freshwater Forested/ Shrub Wetland	Freshwater Pond	Total
27	6.11	20.5	0.6	27.5
28	13.0	25.4	0.2	38.5
Total	**19.4**	**45.9**	**0.8**	**66.0**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Belle Fontaine area can be found in the Environmental Appendix.

6.11.7 Summary of Costs

Table 6.11-6 summarizes the ROM costs at an FY-08 price level by measure for the Belle Fontaine area (planning sub-unit 26).

Table 6.11-6.
Summary of Costs by Measure for the Belle Fontaine Area

Measures	Total Cost to Implement (First Cost) ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0
Measure A 20FT Ring Levee A	$137,600,000	$6,766,000	$1,371,000	N/A	$8,137,000
Measure B 30FT Ring Levee B	$191,900,000	$9,436,000	$1,939,000	N/A	$11,375,000
Measure C 20FT Ring Levee C	$103,900,000	$5,109,000	$989,000	N/A	$6,098,000
Measure D 30FT Ring Levee D	$142,900,000	$7,027,000	$1,414,000	N/A	$8,441,000
Measure E ABFE Nonstructural	$227,800,000	$11,201,000	$10,000	N/A	$11,211,000
Measure F 20FT Nonstructural	$290,726,000	$14,295,000	$10,000	N/A	$14,305,000
Measure G 30FT Nonstructural	$453,067,000	$22,278,000	$10,000	N/A	$22,288,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns. Numbers are rounded to the nearest thousand.

6.11.8 Regional Economic Development (RED)

The purpose of this analysis is to determine the economic impact of the proposed project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Jackson County, Mississippi. The expenditures for the measures are estimated to be $137,600,000 for the 20.0-feet NAVD88 ring levee A measure, $191,900,000 for the 30.0-feet NAVD88 ring levee B measure, $103,900,000 for the 20.0-feet NAVD88 ring levee C measure, $142,900,000 for the 30.0-feet NAVD88 ring levee D measure, $227,800,000 for the ABFE nonstructural measures, $290,726,000 for the 20.0-feet NAVD88 nonstructural measures, and $290,726,000 for the 30.0-feet NAVD88 nonstructural measures. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $27,882,000 for the 20.0-feet NAVD88 ring levee A measure, $39,434,000 for the 30.0-feet NAVD88 ring levee B measure, $20,113,000 for the 20.0-feet NAVD88 ring levee C measure, $28,757,000 for the 30.0-feet NAVD88 ring levee D measure, $203,000 for the ABFE nonstructural measure, $203,000 for the 20.0-feet NAVD88 nonstructural measure, and $203,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100 year period of analysis and an interest rate of 4.875 percent). The following tables, 6.11-7 through 6.11-10, summarize the EIFS model inputs and outputs for the Belle Fontaine area.

Table 6.11-7.
EIFS Model Construction Costs Inputs for the Belle Fontaine Area

	20-foot Ring Levee A	30-foot Ring Levee B	20-foot Ring Levee C	30-foot Ring Levee D	ABFE Nonstructural	20-foot Nonstructural	30-foot Nonstructural

6.12 Evaluation of Pascagoula - Moss Point Area Measures

6.12.1 General

The Pascagoula - Moss Point area, shown in Figure 6.12-1, is located in the southeastern portion of planning unit three along the eastern bank of the Pascagoula River. The area is denoted as planning sub-units 51 and 52 and is depicted in the figure below. The pre-Hurricane Katrina conditions for this area represented a mostly residential community. As shown in table 6.12-1, it was estimated from the field inventorying process that planning sub-units 51 and 52 included 16,158 tax parcels; of which 13,638 contained a structure with some economic value and 2,520 were vacant land. Of those 13,638 parcels that contain structures, 11,449 were residential one-story, 314 were residential two-story, 52 were mobile homes, 1,565 were commercial, and 258 were municipal.

6.12.2 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation
- Preservation of Fish and Wildlife

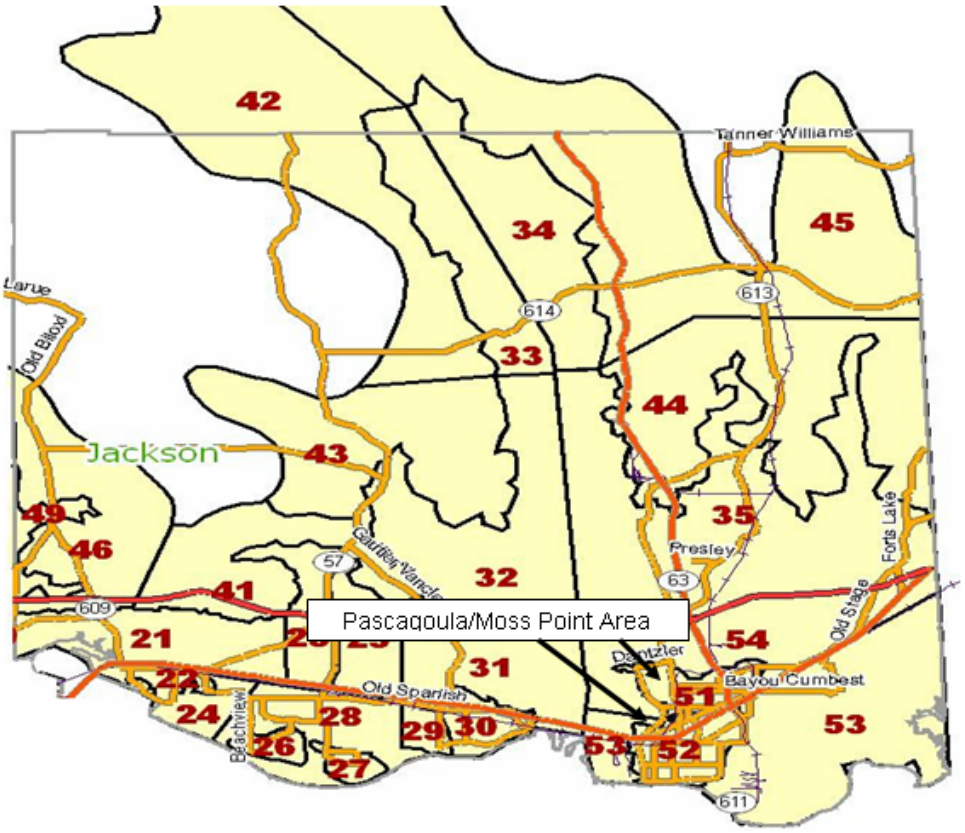

Figure 6.12-1. Pascagoula - Moss Point Area – Planning Sub-units 51 and 52

Table 6.12-1.
Pre-Hurricane Katrina Estimate of Structures for the
Pascagoula-Moss Point Area Planning Sub-units 51 and 52

Structure Categories	Structures by Category
Residential	11,763
Mobile Homes	52
Commercial	1,565
Municipal	258
Vacant Land	2,520
Total Tax Parcels	**16,158**

6.12.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4.875 percent was used in estimating average annual benefits and costs
- Price levels are October, 2007 unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

6.12.4 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit three. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 20.0-feet NAVD88.

- Measure B – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure will provide a ring levee with interior drainage, pumping stations, and roadway access up to a crest elevation of 30.0-feet NAVD88.

- Measure C – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Moss Point area.

- Measure D – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Moss Point area.

- Measure E – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Washington Avenue area.

- Measure F – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Washington Avenue area.

- Measure G – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Moss Point and Washington Avenue areas.

- Measure H – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Moss Point and Washington Avenue areas.

- Measure I – Pascagoula - Moss Point Nonstructural One

This measure includes the acquisition and flood proofing (elevate-in-place) of structures to the FEMA advisory base flood elevation (ABFE).

- Measure J – Pascagoula - Moss Point Nonstructural Two

This measure includes the acquisition and flood proofing of structures to approximately elevation 20-feet NAVD88.

- Measure K – Pascagoula - Moss Point Nonstructural Three

This measure includes the acquisition and flood proofing of structures to approximately elevation 30-feet NAVD88.

Figure 6.12-2 shows the measures for the Pascagoula-Moss Point Area (planning sub-units 51 and 52); the red line represents the approximate footprint of the ring levees A and B, the green line represents the approximate footprints of ring levees C through H, the dark green within the ring levee footprint represents potential ABFE buyout areas and the light green area within the ring levee footprint represents potential flood proof (elevate-in-place) areas.

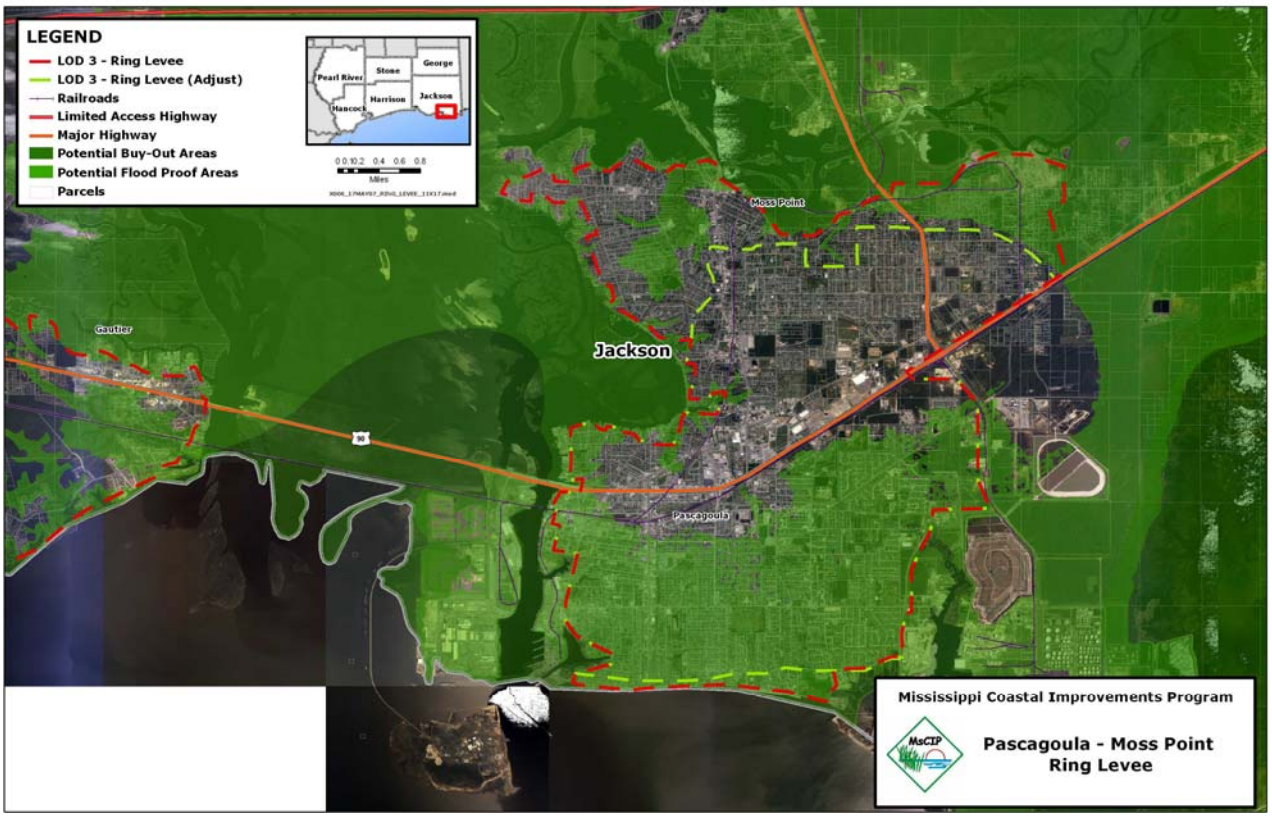

Figure 6.12-2. Display of Potential Measures for the Pascagoula-Moss Point Area (Planning Sub-units 51 and 52)

6.12.5 National Economic Development (NED)

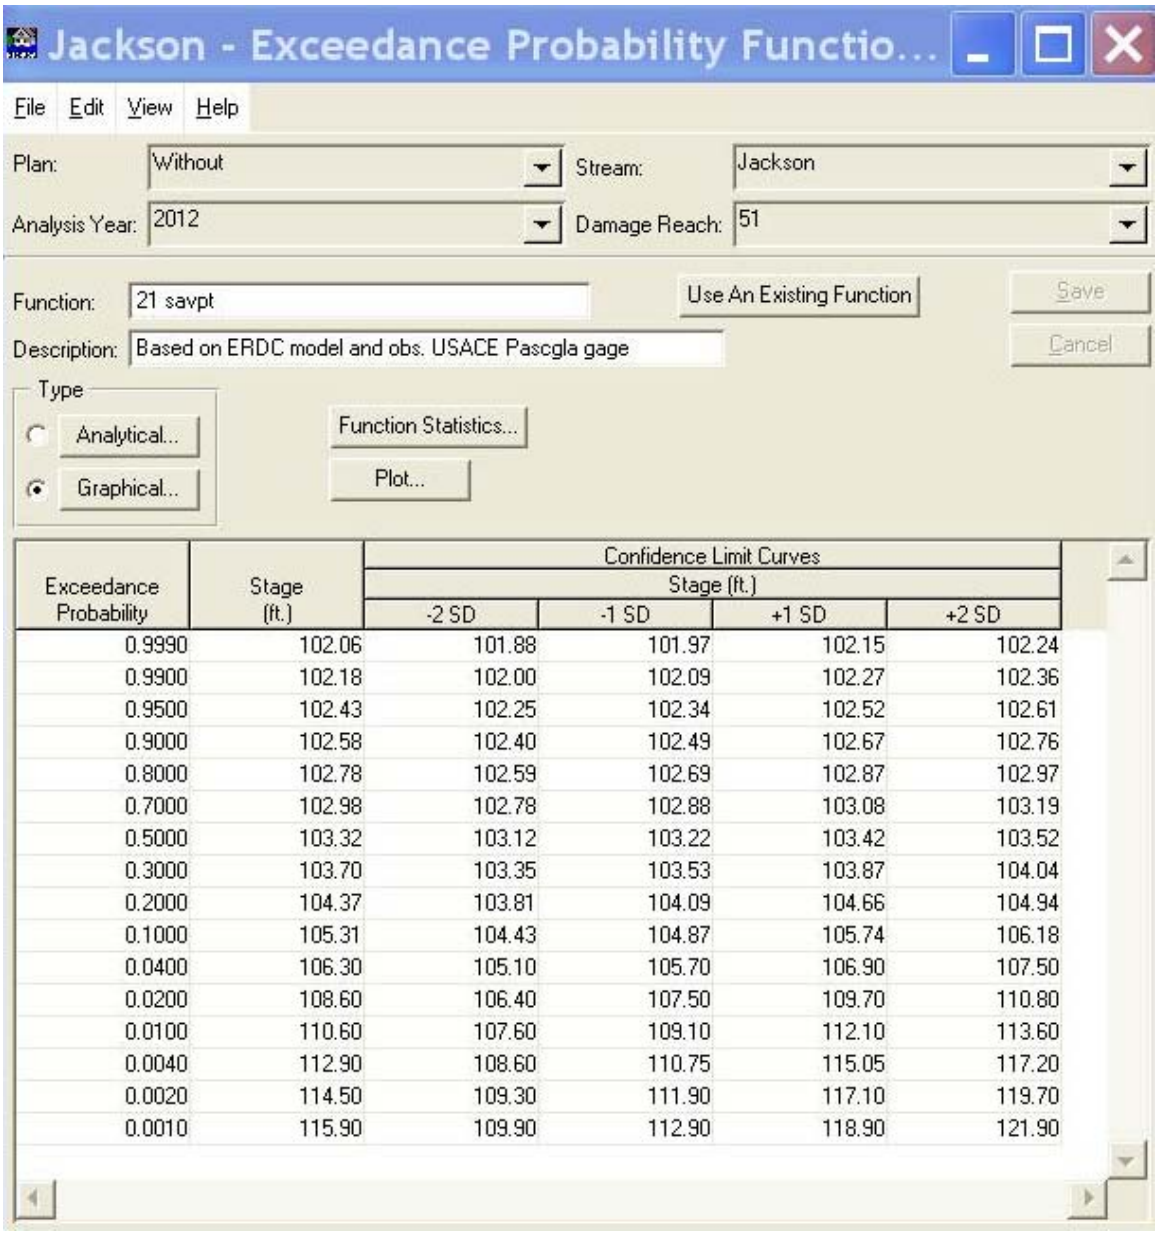
The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.12.5.1 Existing Conditions Post-Hurricane Katrina)

The effects of Hurricane Katrina storm surge were devastating to the Pascagoula-Moss Point Area. Peak water elevation in the area ranged from 14 and 16-feet NAVD88. It is estimated that approximately 3,840 (101 in planning sub-unit 51 and 3,743 in planning sub-unit 52) of the structures in the area (sustained significant inundation damage (fifty-percent or more). Expected redevelopment of the area is described in the following section.

6.12.5.2 Future Without-Project Conditions

Equivalent annual flood damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to future without-project scenarios three, and five, as previously discussed in section 5.3. These future scenarios were chosen because the redevelopment projected for this area is anticipated to return to the pre-Katrina development. Futures scenarios two, four, and six were not used for evaluation purposes since this area is not accommodative for commercial and condominium redevelopment under those mixed redevelopment scenarios (see section 5.3 for more detail).



Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Table 6.12-2 shows structures by category and by elevation. The number of structures per elevation is added to the previous number of structures per elevation in each category. For example, in the residential category there are four structures with an elevation of 1-foot or lower, there are twelve structures with an elevation of 2-feet or less, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Pascagoula-Moss Point area.

Table 6.12-2.
Cumulative Structures by Category and by Estimated First Floor Elevation
Future Scenarios One, Three, and Five
Applicable for Base Year and Most Likely Future Years

Estimated First Floor Elevation (NAVD88)	Residential	Mobile Homes	Commercial	Municipal	Total
1-foot	4	0	0	0	4
2-foot	12	0	0	0	12
3-foot	31	0	0	0	31
4-foot	62	0	0	0	62

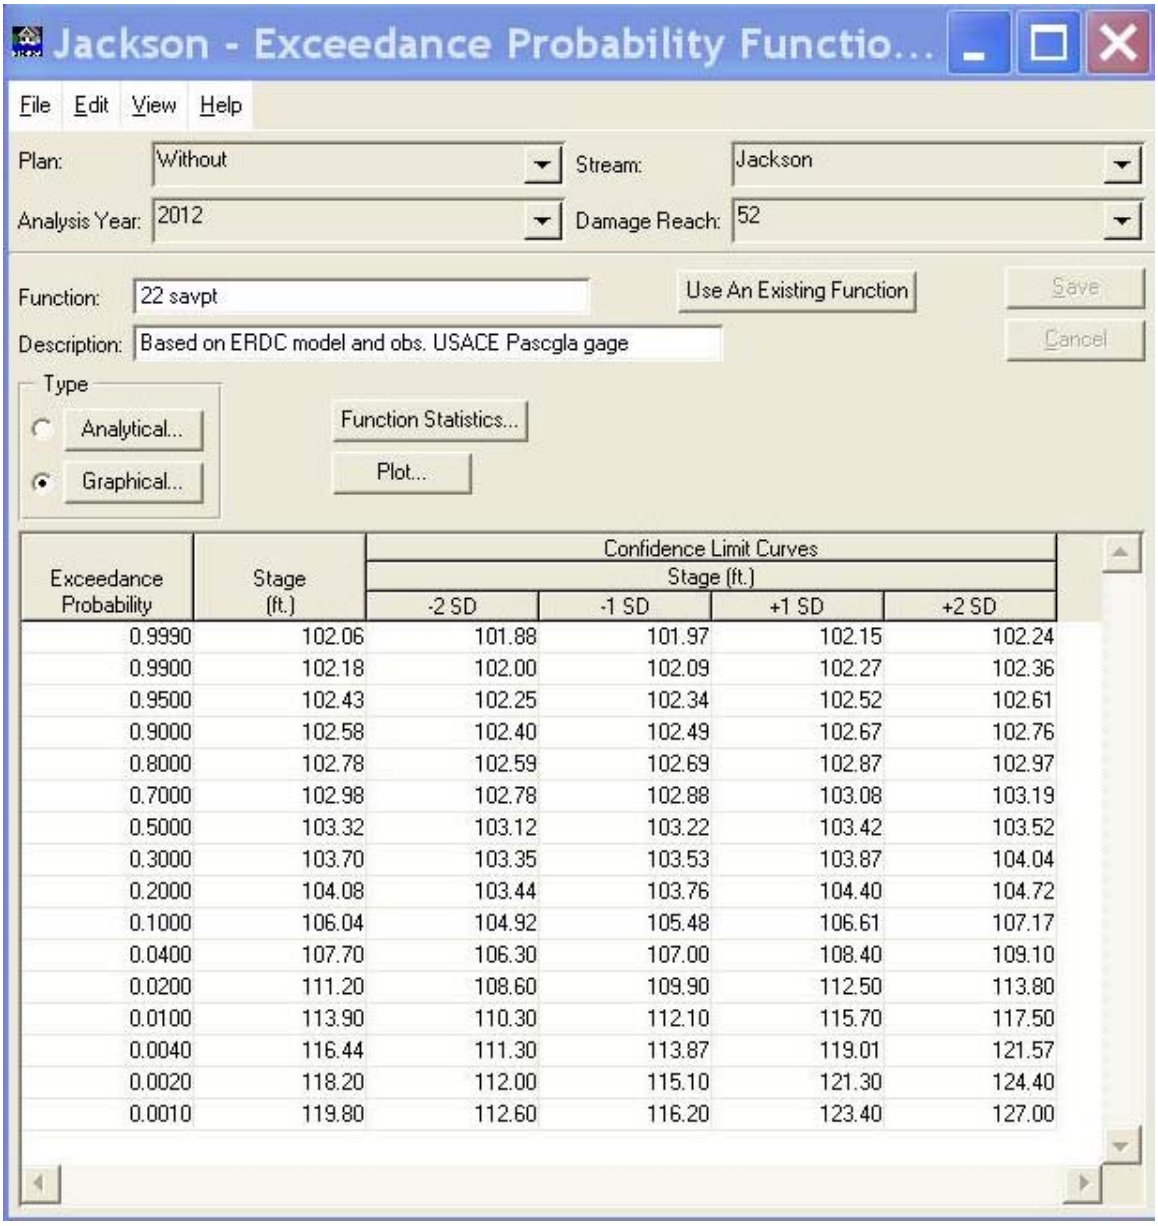
23-foot	11,650	52	1,557	248	13,507
24-foot	11,700	52	1,564	252	13,568
25-foot	11,749	52	1,565	256	13,622
26-foot	11,763	52	1,565	258	13,638
Total	**11,763**	**52**	**1,565**	**258**	**13,638**



Future scenario three is the full redevelopment of assets within the study area by the year 2012. Under this scenario, assets will be rebuilt as they were pre-Hurricane Katrina. For example, if the asset was a residential structure pre-Hurricane Katrina it will be rebuilt as a residential structure; commercial structures will be built back to commercial structures; etc. Basically, future scenario three is the same structure inventory as future scenario one with the addition of an expected relative sea level rise over the 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $26,078,000 (rounded to the nearest thousand dollars). The total number of structures in this scenario are the same as in scenario one and can be seen above in table 6.12-2. Figures 6.12-3 and 6.12-4 depict the base years for planning sub-units 51 and 52 respectively, and figures 6.12-5 and 6.12-6 show the most likely future year exceedance probability functions for planning sub-units 51 and 52. The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most

likely future year exceedance probability function depicted in figure 6.12-5 ad 6.12-6 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

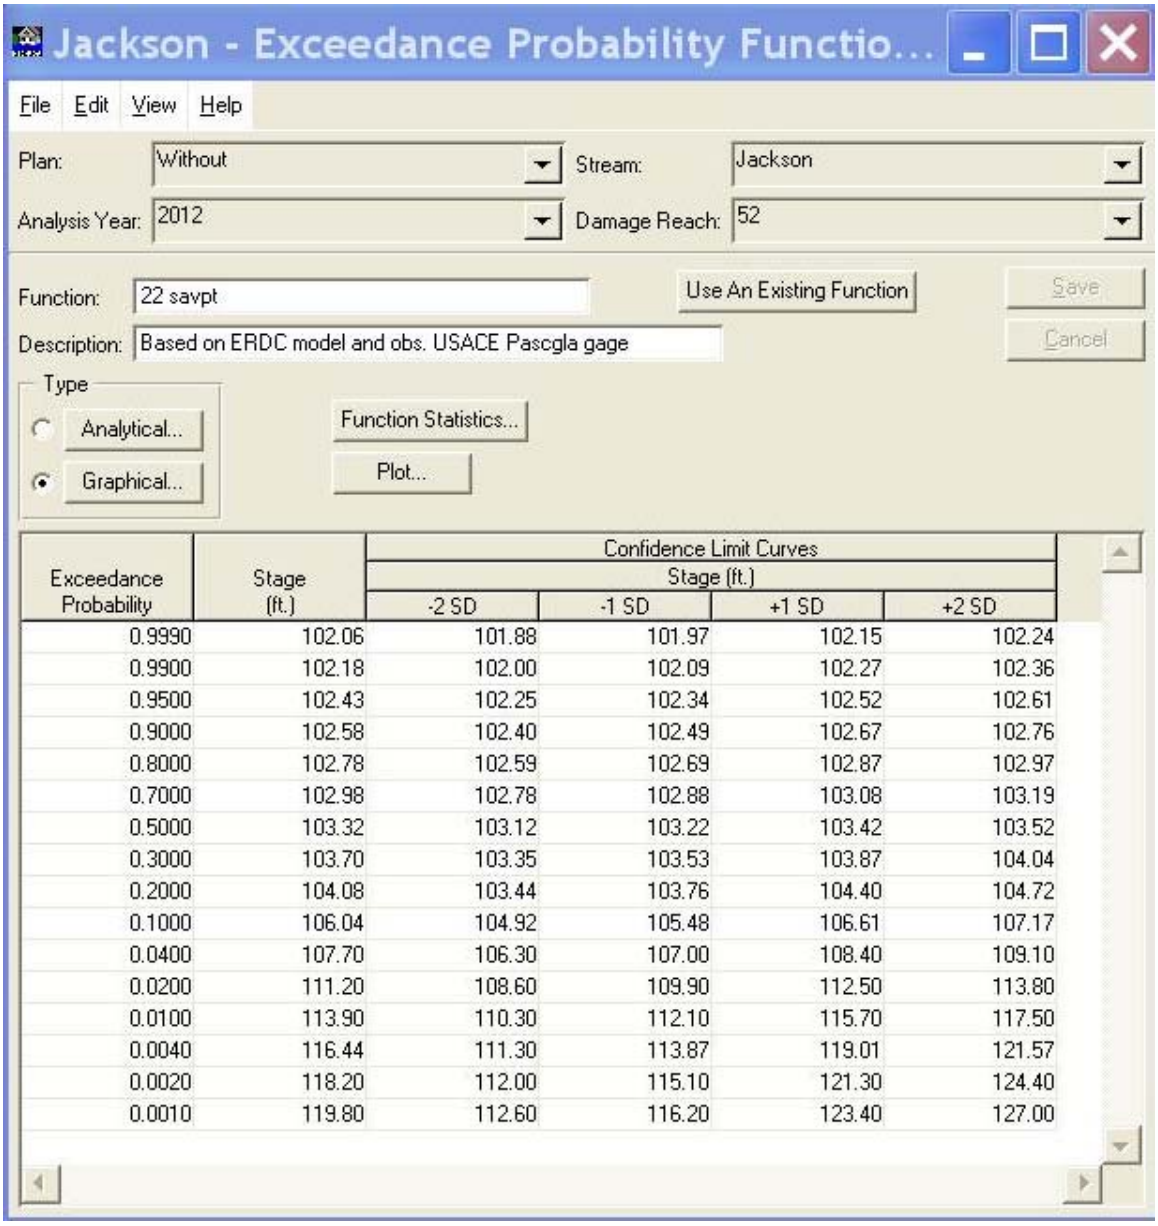
Figure 6.12-6. Future Scenario 3 Most Likely Future Year (2012) Exceedance Probability Function for the Planning Sub-unit 52 – Includes an adjustment for relative sea level rise.



Future scenario five is the same as future scenario one with the addition of a high relative sea level rise 100-year period of analysis (2012–2111). Equivalent annual damages that could occur under this scenario are $32,812,000 (rounded to the nearest thousand). These damages represent a approximately a twenty-six-percent (25.8%) increase over the expected relative sea level rise accounted for in future scenario three. The total number of structures in this scenario is the same as in scenarios one and three and can be seen above in table 6.12-2. Figures 6.12-7 and 6.12-8 depict the base year for planning sub-units 51 and 52 respectively, and figures 6.12-9 and 6.12-10 show the most likely future year exceedance probability functions for planning sub-units 51 and 52. The exceedance probability functions are for still water elevation (SWEL's) and based on a combination of observed data from USACE gauges and from modeling efforts conducted by the Engineer Research and Development Center (ERDC). The most likely future year exceedance probability

function depicted in figures 6.12-9 and 6.12-10 includes an adjustment for expected relative sea level rise over the 100-year period of analysis. **Note**: Due to uncertainty issues regarding the first floor elevations, a base of 100-feet was applied to the exceedance probability functions and the first floor elevations. For example, if the stage for a given event probability shows 102-feet, the stage is really 2-feet. For more detail on the estimation and use of the exceedance probability functions see the Engineering Appendix.

Figure 6.12-10. Future Scenario 5 Most Likely Future Year (2012) Exceedance Probability Function for the Planning Sub-unit 52 – Includes an adjustment for high relative sea level rise

6.12.5.3 Equivalent annual damages Reduced

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HECFDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without project inventory except that footprints of levees and acquisitions were deleted from the inventory and flood proofed structures (structures to be raised in place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- Measure A – Pascagoula - Moss Point Ring Levee A at elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 589 parcels that were deleted out of the inventory. These parcels represent the footprint of the 20.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its implementation. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Pascagoula - Moss Point Ring Levee B at elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 666 parcels that were deleted out of the inventory. These parcels represent the footprint of the 30.0-feet NAVD88 elevation ring levee and some portion of the total would have to be purchased for its implementation. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Moss Point area.

- Measure D – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Moss Point area.

- Measure E – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Washington Avenue area.

- Measure F – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Washington Avenue area.

- Measure G – Pascagoula - Moss Point Ring Levee at Elevation 20.0-feet NAVD88

This measure includes a combination of a ring levee at 20-feet NAVD88 on an alternate footprint from measure A that would include the acquisition of structures and parcels in the Moss Point and Washington Avenue areas.

- Measure H – Pascagoula - Moss Point Ring Levee Elevation 30.0-feet NAVD88

This measure includes a combination of a ring levee at 30-feet NAVD88 on an alternate footprint from measure B that would include the acquisition of structures and parcels in the Moss Point and Washington Avenue areas.

- Measure I – Pascagoula - Moss Point Nonstructural One

This measure includes the acquisition of 145 (0 in planning sub-unit 51 and 145 in planning sub-unit 52) parcels that include a structure and the flood proofing (raise structure in place) of 7,603 (781 in planning sub-unit 51 and 6,822 in planning sub-unit 52) structures to an elevation of 12.0-feet NAVD88 for planning sub-unit 51 and 14.95-feet for planning sub-unit 52. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was determined to be approximately the 100-year level of protection and is defined as still water elevation, plus wave run-up plus an estimate for waves (depth divided by two), and is the minimum elevation that a nonstructural plan could provide.

- Measure J – Pascagoula - Moss Point Nonstructural Two to elevation 20.0-feet NAVD88

This measure includes the acquisition of 2,333 (718 in planning sub-unit 51 and 1,615 in planning sub-unit 52) parcels that include a structure and the flood proofing (raise structure in place) of 5,427 (64 in planning sub-unit 51 and 5,363 in planning sub-unit 52) structures to an elevation of 20.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levees at elevation 20.0-feet NAVD88.

- Measure K – Pascagoula - Moss Point Nonstructural Three to elevation 30.0-feet NAVD88

This measure includes the acquisition of 7,760 (782 in planning sub-unit 51 and 6,978 in planning sub-unit 52) parcels that include a structure to an elevation of 30.0-feet NAVD88. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the Nonstructural Appendix. This elevation was chosen to show a direct comparison to the ring levees at elevation 30.0-feet NAVD88.

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damage is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table." Table 6.12-3 summarizes the equivalent annual without-project damages, damages reduced, and residual damages by measure and by future scenario.

Table 6.12-3.
Summary of Damages by Measure

Measures	Equivalent annual damages Future 3 ($)	Equivalent Annual Damage Reduction Future 3 ($)	Residual Damage Future 3 ($)	Equivalent annual damages Future 5 ($)	Equivalent Annual Damage Reduction Future 5 ($)	Residual Damage Future 5 ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 20FT Ring Levee A	$26,078,000	$24,244,000	$1,834,000	$32,812,000	$30,616,000	$2,196,000

Measure H 30FT Ring Levee H	$26,078,000	$26,078,000	$0	$32,812,000	$31,212,000	$1,600,000
Measure I ABFE Nonstructural	$26,078,000	$17,199,000	$8,879,000	$32,812,000	$21,629,000	$11,183,000
Measure J 20FT Nonstructural	$26,078,000	$24,349,000	$1,729,000	$32,812,000	$28,815,000	$3,997,000
Measure K 30FT Nonstructural	$26,078,000	$25,454,000	$624,000	$32,812,000	$30,115,000	$2,697,000

Damages are rounded to the nearest thousand dollars.

6.12.6 Environmental Quality (EQ)

6.12.6.1 Impacts of Ring Levee Measures

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.12-4 and 6.12-5 show the impacts of the Pascagoula/Moss Point ring levees at elevations 20.0-feet NAVD88, and 30.0-feet NAVD88 respectively.

Table 6.12-4.
Wetland Acres Impacted by Elevation 20' Pascagoula/Moss Point Ring Levee A

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
51	0.5	2.8	0.1	3.2	0.5	7.0
52	0.0	2.4	0.0	14.3	0.1	16.8
53	0.3	3.2	0.0	3.8	0.0	7.2
54	0.6	5.2	0.5	19.6	0.1	25.9
Total	**1.4**	**13.6**	**0.5**	**40.8**	**0.7**	**57.0**

Table 6.12-5.
Wetland Acres Impacted by Elevation 30' Pascagoula/Moss Point Ring Levee B

Reach ID	Estuarine and Marine Deepwater	Estuarine and Marine Wetland	Freshwater Emergent Wetland	Freshwater Forested/Shrub Wetland	Freshwater Pond	Total
51	0.5	3.5	0.1	4.8	0.8	9.7
52	0.0	3.2	0.0	22.7	0.1	26.0
53	1.5	4.8	0.0	5.8	0.0	12.1
54	1.2	7.9	0.6	26.3	0.2	36.2
Total	**3.2**	**19.3**	**0.7**	**59.7**	**1.1**	**84.1**

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Pascagoula-Moss Point area can be found in the Environmental Appendix.

6.12.7 Summary of Costs

Table 6.12-6 summarizes the ROM costs by measure for the Pascagoula-Moss Point area.

Table 6.12-6.
Summary of Costs by Measure for the Pascagoula-Moss Point Area

Measures	Implement Costs (FY-08) ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0
Measure A 20FT Ring Levee A	$699,000,000	$34,371,000	$5,719,000	N/A	$40,090,000
Measure B 30FT Ring Levee B	$916,000,000	$45,041,000	$8,309,000	N/A	$53,350,000
Measure C 20FT Ring Levee C	$671,600,000	$33,023,000	$4,658,000	N/A	$37,681,000
Measure D 30FT Ring Levee D	$849,900,000	$41,791,000	$6,707,000	N/A	$48,498,000
Measure E 20FT Ring Levee E	$874,400,000	$42,995,000	$3,761,000	N/A	$46,756,000
Measure F 30FT Ring Levee F	$1,013,200,000	$49,820,000	$5,423,000	N/A	$55,243,000
Measure G 20FT Ring Levee G	$921,400,000	$45,306,000	$3,537,000	N/A	$48,843,000
Measure H 30FT Ring Levee H	$1,057,700,000	$52,008,000	$5,197,000	N/A	$57,205,000
Measure I ABFE Nonstructural	$2,272,975,000	$111,765,000	$20,000	N/A	$111,785,000
Measure J 20FT Nonstructural	$5,105,777,000	$251,057,000	$20,000	N/A	$251,077,000
Measure K 30FT Nonstructural	$5,105,777,000	$251,057,000	$20,000	N/A	$251,077,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns. Numbers are rounded to the nearest thousand.

6.12.8 Regional Economic Development (RED)

The purpose of this analysis is to determine the economic impact of the proposed project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of Jackson County, Mississippi. The expenditures, shown in Table 6.12-6, for the measures are estimated to be $699,000,000 for the 20.0-feet ring levee A measure, $916,000,000 for the 30.0-feet ring levee B measure, $671,600,000 for the 20.0-feet NAVD88 ring levee C measure, $849,900,000 for the 30.0-feet NAVD88 ring levee D measure, $874,400,000 for the 20.0-feet NAVD88 ring levee E measure, $1,013,200,000 for the 30.0-feet NAVD88 ring levee F measure, $921,400,000 for the 20.0-feet NAVD88 ring levee G measure, $1,057,700,000 for the 30.0-feet NAVD88 ring levee H measure, $2,272,975,000 for the ABFE nonstructural measure, $5,105,777,000 for the 20.0-feet NAVD88 nonstructural measure, and $5,105,777,000 for the 30.0-feet NAVD88 nonstructural measure. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $116,308,000 for the 20.0-feet NAVD88 ring levee A measure, $168,981,000 for the 30.0-feet NAVD88 ring levee B measure, $94,730,000 for the 20.0-feet NAVD88 ring levee C measure, $136,401,000 for the 30.0-feet NAVD88 ring levee D measure, $76,488,000 for the 20.0-feet NAVD88 ring levee E measure, $110,288,000 for the 30.0-feet NAVD88 ring levee F measure, $71,932,000 for the 20.0-feet NAVD88 ring levee G measure, $105,692,000 for the 30.0-feet NAVD88 ring levee H measure $406,000 for the ABFE nonstructural measure, $406,000 for the 20.0-feet NAVD88 nonstructural measure, and $406,000 for the 30.0-feet NAVD88 nonstructural measure respectively (assuming a 100- year period of analysis and an interest rate of 4.875-percent). The following tables, 6.12-7 through 6.12-14, summarize the EIFS model inputs and outputs for the Pascagoula-Moss Point Area measures.

Table 6.12-7.
EIFS Model Implementation Cost Inputs for the Pascagoula/Moss Point Area

6.13 Evaluation of Bayou Cumbest Area Ecosystem Restoration Measures

This Section describes the evaluation of measures for the Bayou Cumbest area. Bayou Cumbest is approximately 373 acres in planning unit three, planning sub-unit fifty-three just west of the Mississippi and Alabama state line. This area experienced water elevations between 16.0 and 18.0 ft. NAVD88 from Hurricane Katrina storm surge. Figure 6.13-1 shows the location of the Bayou Cumbest area.

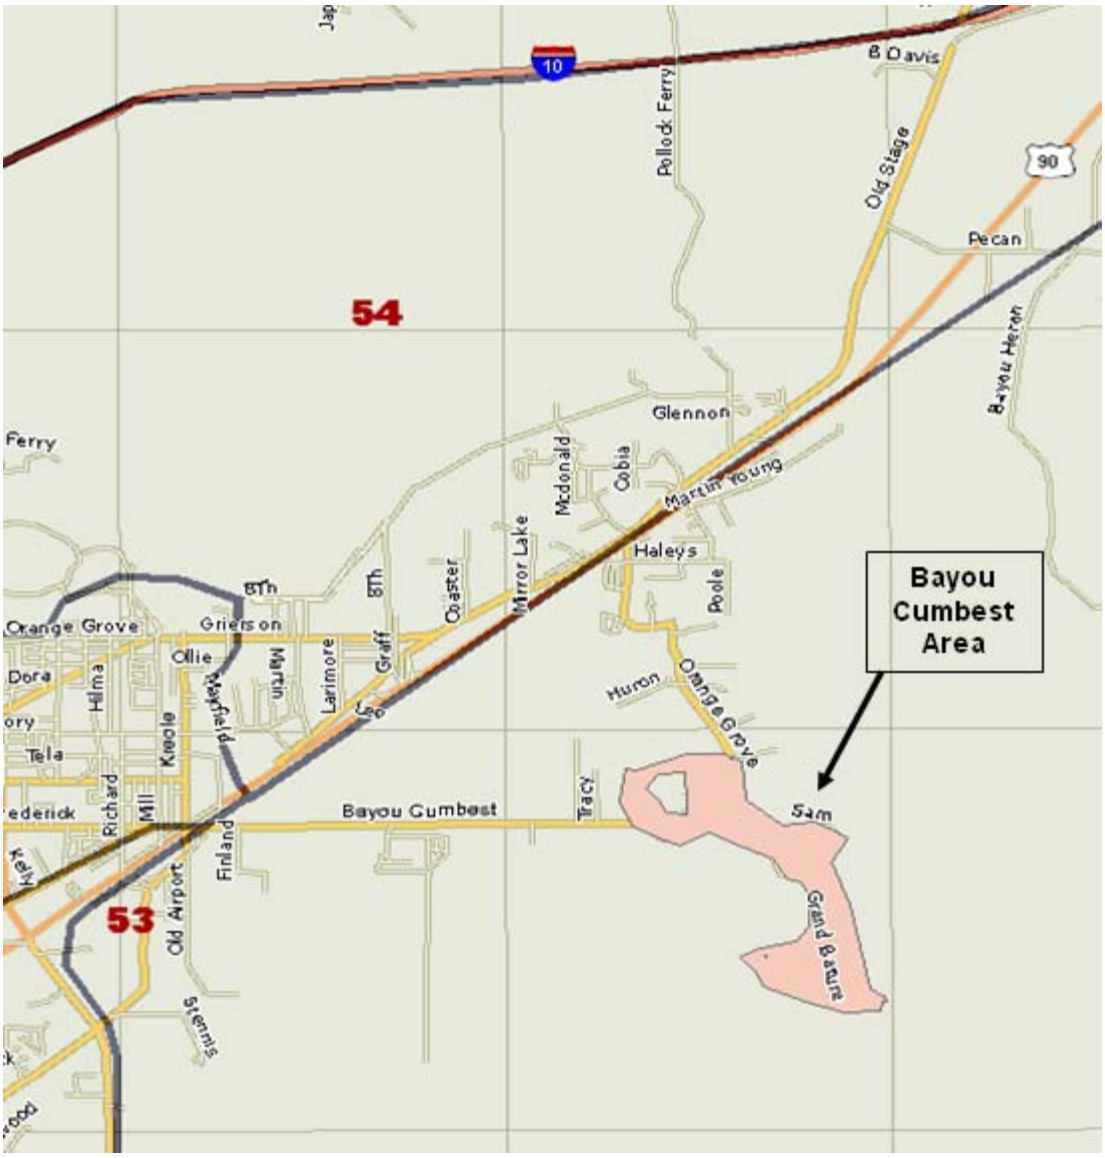

Figure 6.13-1 Bayou Cumbest Area, Planning Unit Three, Planning Sub-Unit fifty-three

This area was specifically identified for its ecosystem restoration potential using a Spatial Decision Support System (SDSS) tool, which was developed for the MsCIP Comprehensive Plan by the Engineer Research and Development Center (ERDC). The development of the GIS based SDSS tool allowed the Corps, Mobile District, working in cooperation with the USFWS and MDMR, to identify and prioritize potential wetland restoration areas throughout Coastal Mississippi. A subset of

potential restoration sites were identified by the SDSS tool and then ground-truthed by the MsCIP environmental team, including ERDC, Corps, MDMR, and USFWS. This interagency team allowed us to both confirm the accuracy of the SDSS results and to collect additional on-site information pertinent to restoration efforts.

There are some major benefits in using a GIS-based SDSS approach to wetland restoration. First, it allows for the relatively rapid assessment of the large number of restoration sites across the wide study area. Second, potential sites can be evaluated and restored in a watershed or landscape context, which allows us to comprehensively evaluate the overall natural system. This approach can maximize the benefits of wetland restoration, as opposed to simply restoring wetlands where convenient or where property is available. Essentially use of this SDSS tool allowed the MsCIP environmental team to assess the entire coastline as a holistic natural system; thus, the team was more effectively able to analyze needs in Coastal Mississippi.

The SDSS tool evaluated potential wetland restoration sites that had been initially selected based on having a non-natural land cover (i.e. urban, deforested, and agricultural land cover, based on MDMR 2001 land cover GIS layer) and were located in the 100-year floodplain. Numerous potential environmental restorations sites were initially identified. This initial group of sites was narrowed down based on the results of the SDSS. Sites with the following characteristics were screened out:

- < 5 acres in size
- Restorability class of Low or Medium Low
- Habitat class of Low or Medium Low
- Storm Surge/Flood Protection class of Low

6.13.1 Environmental Quality (EQ)

6.13.1.1 Ecosystem Restoration Assumptions

- In order for the Bayou Cumbest site to undergo ecosystem restoration, it is assumed that there will be buy-outs of properties within the area.
- A 50-year period of analysis was used to determine average annual outputs and costs.
- Construction implementation time is estimated to be twelve months.

6.13.1.2 Ecosystem Restoration Objectives

The following ecosystem restoration objectives were developed:

- Restore marsh to historical (pre-development ~1950's) conditions
- Provide storm surge protection
- Restore native tidal wetland plant community
- Provide fish and tidal wildlife habitat

6.13.1.3 Ecosystem Restoration Management Measures

Proposed restoration management measures are listed in table 6.13-1. Narrative descriptions of each management measure follow this table.

Table 6.13-1.
Ecosystem Restoration Management Measures

Management Measure	Description
No Action	No Action
1	Excavate Old Fill Material
2	Remove Exotic Species
3	Fill Existing Artificial Ditches
4 *a* *b* *c*	Plant Native Vegetation - 0.5 meter spacing - 1.0 meter spacing - 2.0 meter spacing

6.13.1.4 Excavate Old Fill Material (1)

This management measure must be included in all measures for the restoration to be successful. It includes 90-95 percent removal of existing exotic species in the excavated areas. This measure positively affects the hydrologic regime.

6.13.1.5 Remove Exotic Species from Non-Excavated Areas and Maintenance of Exotics in All Areas over the Project Life (2)

This management measure must be included in all measures for the restoration to be successful. It includes 100 percent removal of exotic species from non-excavated areas over the life of the project. The exotic species include Chinese Tallow, Phragmites, and Cogon Grass. This measure affects the percentage of the area covered by exotic species.

6.13.1.6 Fill Existing Artificial Ditches and Channels (3)

This management measure does not need to be included in all measures for the restoration to be successful. It includes 100 percent removal of existing artificial ditches and channels. This measure provides additional positive affects to the hydrologic regime.

6.13.1.7 Plant Native Vegetation (4)

This management measure must be included in all measures for the restoration to be successful. There are three different planting density options: (a) 0.5 meters spacing, (b) 1.0 meter spacing, and (c) 2.0 meter spacing. Planting emergent tidal marsh at varying densities will result in obtaining desired environmental output at varying years and costs. It is estimated that 2 re-planting efforts would be required for the two least dense plantings: 1.0 and 2.0 meter spacing. It is estimated that the 0.5 meter spacing will achieve full benefits in about 5 years while the 1.0 meter spacing and 2.0 meter spacing will achieve full benefits in about 7 and 10 years, respectively.

This measure affects the percent cover by woody plant species, wildlife habitat diversity, vegetation height, wetland indicator status and the mean percent cover emergent plant species.

6.13.1.8 Ecosystem Restoration Measures

These management measures were combined to create six measures. Each measure includes the mandatory management measures of excavating old fill material, removing exotic plant species from non-excavated areas, and planting native vegetation. Since there are three different planting densities, three measures are created with this combination of management measures. When the

management measure of filling existing artificial ditches is added to this combination, this creates another three measures.

All measures will restore 110 acres to tidal marsh. Measure 1 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, filling existing artificial ditches, and planting native vegetation such as Spartina alterniflora (Smooth Cordgrass) at the seaward edge of marsh; Juncus roemerianus (Black Needle Rush) at a slightly higher elevation; and Spartina patens (Saltmeadow Cordgrass) at a slightly higher elevation at a density of 0.5 meter. Measure 2 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, filling existing artificial ditches, and planting native vegetation at a density of 1.0 meter. Measure 3 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, filling existing artificial ditches, and planting native vegetation at a density of 2.0 meter. Measure 4 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas, and planting native vegetation at a density of 0.5 meters. Measure 5 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas and planting native vegetation at a density of 1.0 meter. Measure 6 consists of restoring the study area by excavating old fill material, removing exotic plant species from non-excavated areas and planting native vegetation at a density of 2.0 meters. Figure 6.13-2 shows the location of the Bayou Cumbest restoration site. Table 6.13-2 displays a description of each ecosystem restoration measure.

6	1 + 2 + 4c	Excavate Fill Remove Exotics Plant at Density 2.0m

6.13.3.9 Ecosystem Restoration Benefits and Costs

Benefits are measured in terms of Average Annual Functional Units (AAFU). The Hydrogeomorphic (HGM) approach was used to assess wetland function. A HGM assessment was performed in 2000 using the Regional Guidebook for Applying the HGM Approach to Assessing Wetland Functions of Wet Pine Flats on Mineral Soils in the Atlantic and Gulf Coastal Plains. Results from this assessment were used to establish baseline (current) conditions and, ultimately, to measure the functional unit benefits resulting from different restoration measures. Table 6.13-3 shows the total functional units under each measure and the AAFU net benefit. It is assumed that functional units will remain the same under existing conditions and the no action measure. To calculate the AAFU net benefit, it is assumed all benefits are immediately accrued following measure implementation, and that the benefits are sustainable over the life of the project. Therefore, the AAFU net benefit was calculated as the difference between the total functional units for the ecosystem restoration measure and the total functional units for the no action measure. Table 6.13-4 summarizes the ROM costs at an FY-08 price level Bayou Cumbest ecosystem restoration measures.

Table 6.13-3.
Summary of Benefits

Measure	Measure Description	AAFU Units Benefits
No Action	No Action	0
Measure 1	Excavate Fill Remove Exotics Fill Ditches Plant at Density 0.5m	191
Measure 2	Excavate Fill Remove Exotics Fill Ditches Plant at Density 1.0m	188
Measure 3	Excavate Fill Remove Exotics Fill Ditches Plant at Density 2.0m	184
Measure 4	Excavate Fill Remove Exotics Plant at Density 0.5m	172
Measure 5	Excavate Fill Remove Exotics Plant at Density 1.0m	169
Measure 6	Excavate Fill Remove Exotics Plant at Density 2.0m	164

Table 6.13-4.
Summary of Costs by Measure for Bayou Cumbest

Measure	Measure Description	Implementation Cost (FY-08)	IDC	Investment Cost	AAIC[1]	AAO&M[2]	AAC[3]
0	No Action	$0	$0	$0	$0	$0	$0
1	Excavate Fill Remove Exotics Fill Ditches Plant at Density 0.5m	$28,000,000	$620,000	$28,600,000	$1,538,000	$2,000	$1,540,000
2	Excavate Fill Remove Exotics Fill Ditches Plant at Density 1.0m	$23,350,000	$520,000	$23,870,000	$1,282,000	$114,000	$1,396,000
3	Excavate Fill Remove Exotics Fill Ditches Plant at Density 2.0m	$21,030,000	$470,000	$21,500,000	$1,155,000	$112,000	$1,267,000
4	Excavate Fill Remove Exotics Plant at Density 0.5m	$27,990,000	$620,000	$28,610,000	$1,537,000	$2,000	$1,539,000
5	Excavate Fill Remove Exotics Plant at Density 1.0m	$23,340,000	$520,000	$23,860,000	$1,282,000	$114,000	$1,396,000
6	Excavate Fill Remove Exotics Plant at Density 2.0m	$21,020,000	$470,000	$21,480,000	$1,154,000	$112,000	$1,266,000

6.13.3.10 Comparison of Measures

Table 6.13-5 display all measures with their respective AAC and AAFU in increasing order of AAFU.

Table 6.13-5.
All Measures: Average Annual Costs and Average Annual Functional Units

Measure	AAC	AAFU
No Action	$0	0
6	$1,266,000	164
5	$1,396,000	169
4	$1,539,000	172
3	$1,267,000	184
2	$1,396,000	188
1	$1,540,000	191

Note: The AAC values are rounded to the nearest thousand.

To determine if a measure is cost effective, economically inefficient measures must first be identified and eliminated. An economically inefficient measure is a measure that cost more for the same level of benefit. No measures are eliminated for the reason of economic inefficiency because each measure produces a different level of benefit.

Lastly, economically ineffective measures are identified and eliminated to determine which measures are cost effective. An economically ineffective measure is a measure that cost more or the same as a subsequent measure but produces less benefit than that subsequent measure. As shaded in table 6.13-6, the measures 4 and 5 were eliminated because they produced less benefit at greater cost than a subsequent measure. For example, Measure 4 produces 172 AAFU at an AAC of $1,539,000 while Measure 3 produces 184 AAFU at an AAC $1,267,000. Measure 4 produces less AAFU at a greater cost than Measure 3. Therefore, Measure 4 is eliminated. As shown in table 6.13-7 and plotted in figure 6.13-3, the cost effective measures are Measure 1, Measure 2, Measure 3, and Measure 6.

Table 6.13-6.
Elimination of Economically Ineffective Measures

Measure	Measure Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
6	Excavate Fill Remove Exotics Plant at Density 2.0m	$1,266,000	164	Yes
5	Excavate Fill Remove Exotics Plant at Density 1.0m	$1,396,000	169	No
4	Excavate Fill Remove Exotics Plant at Density 0.5m	$1,539,000	172	No
3	Excavate Fill Remove Exotics Fill Ditches Plant at Density 2.0m	$1,267,000	184	Yes
2	Excavate Fill Remove Exotics Fill Ditches Plant at Density 1.0m	$1,396,000	188	Yes
1	Excavate Fill Remove Exotics Fill Ditches Plant at Density 0.5m	$1,540,000	191	Yes

Note: The AAC values are rounded to the nearest thousand.

1	Excavate Fill Remove Exotics Fill Ditches Plant at Density 0.5m	$1,540,000	191	Yes

Note: The AAC values are rounded to the nearest thousand.

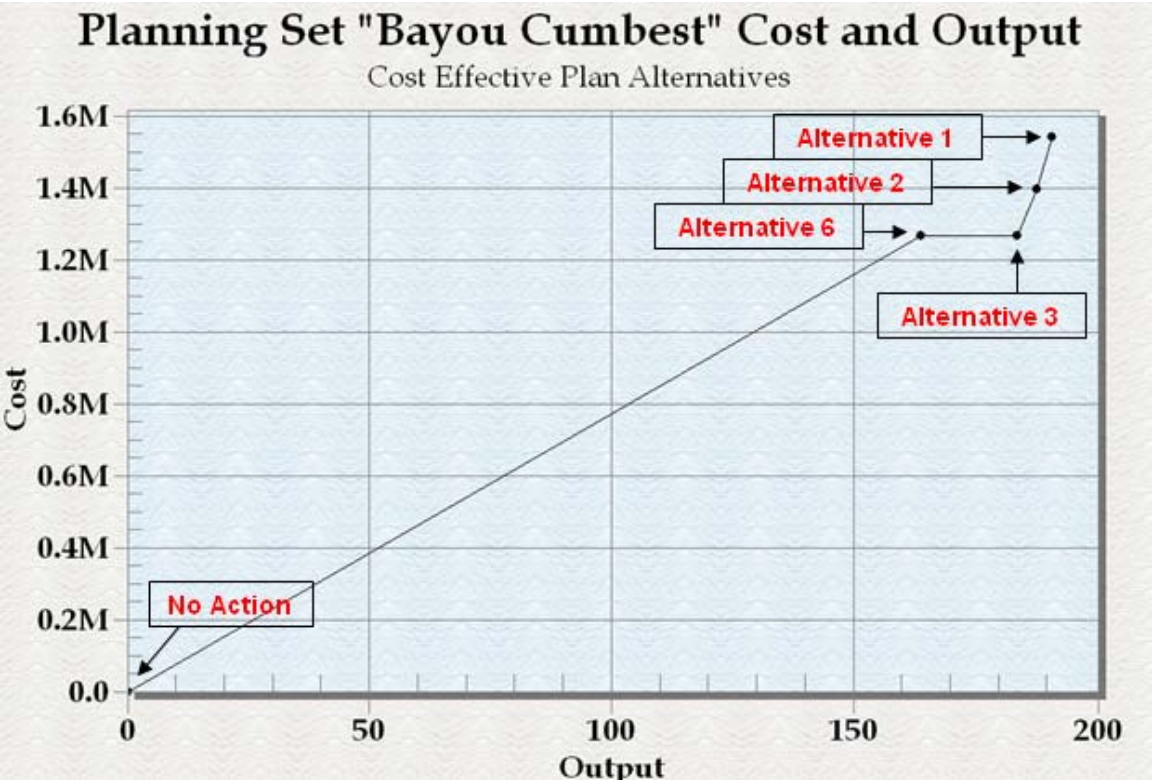

Figure 6.13-3 Cost Effective Measures for Bayou Cumbest Area

6.13.4 Regional Economic Development (RED)

The purpose of this section is to show the economic impact of the proposed project alternatives on business (sales volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Jackson County, Mississippi. The expenditures for the alternatives are estimated to be $28,000,000 for Alternative 1, $23,400,000 for the Alternative 2, $21,000,000 for Alternative 3, and $21,000,000 for Alternative 6. Moreover, the present worth of the operation and maintenance (O&M) expenditures are estimated to be $43,000 for Alternative 1, $2,106,000 for Alternative 2, $2,071,000 for Alternative 3, and $2,071,000 for Alternative 6, (assuming a 50 year period of analysis and an interest rate of 4.875 percent). The following tables, 6.13-8 through 6.13-11 summarize the EIFS model inputs and outputs for the cost effective measures.

Table 6.13-8.
EIFS Model Implementation Cost Inputs for Bayou Cumbest Ecosystem

	No Action	Alternative 1	Alternative 2	Alternative 3	Alternative 6
Region of Influence (ROI)	Jackson County	Jackson County	Jackson County	Jackson County	Jackson County
Change in Local Expenditures	$0	$28,000,000	$23,400,000	$21,000,000	$21,000,000

Based of the given inputs the outputs are as follows:

Table 6.13-9.

6.14 Dantzler Area Ecosystem Restoration Measures

This section describes the evaluation of ecosystem restoration measures at the Dantzler area that is located within planning sub-unit 53, which is part of planning unit three. The total area includes 385 acres of state owned land. This area was selected for ecosystem restoration using the Decision Support System, a GIS based model created by the Corps' Engineer Research and Development Center (ERDC). For more details on the selection process for ecosystem restoration sites see the Economic Appendix. Figure 6.14-1 shows the location of the Dantzler area.

6.14.1 Formulation of Measures

6.14.1.1 Assumptions

In order for the Dantzler site to undergo ecosystem restoration, it is assumed that all property and rights of way are owned by the State of Mississippi. Costs and benefits are based on a 50-year period of analysis and an FY-08 discount rate of 4.875-percent.

6.14.1.2 Objectives

The following objectives were developed for ecosystem restoration:

- Restore native wetland plant communities
- Restore natural fire regime
- Restore natural hydrology
- Restore fish and wildlife habitat
- Provide storm surge protection

Figure 6.14-1. Location of the Dantzler Ecosystem Restoration Area

6.14.1.3 Ecosystem Restoration Management Measures

Proposed restoration management measures are listed in table 6.14-1. Narrative descriptions of each management measure follow this table.

Table 6.14-1.
Ecosystem Restoration Management Measures

Management Measure	Description
No Action	No Action
1 *a* *b*	Maintain Native Savannah Vegetation *By Burning Every 3Years* *By Mowing Annually*
2	Remove Exotics and Plantation Pine
3	Fill Artificial Ditches

6.14.1.3.1 Maintain Native Savannah Vegetation (1)

This management measure must be included in all measures for the restoration to be successful. There are two methods that will be analyzed for maintaining vegetation: (a) burning and (b) mowing. Fire benefits this ecosystem in many different ways. It creates a bare seedbed for pine seedlings and other fire dependent plants, reduces fuel loads and recycles nutrients. Periodic burning promotes early successional plants that are important to many species of wildlife indigenous to this ecosystem. Many of the plant species found in this ecosystem are fire dependent; for example, the federally endangered American Chaff seed flowers almost exclusively after a fire. It has been reduced to a fraction of its original range due to fire suppression and habitat destruction. Fire suppression is mainly due to liability issues and fear of litigation.

Mowing is a mechanical alternative that many land managers use to maintain early successional habitats. Although it is successful to some extent, it fails to provide all the necessary components that come from prescribed fire. This method also has a negative effect. Mowing requires the use of heavy equipment in sensitive areas. Tractors can create ruts in saturated soils, creating hydrologic problems and micro site conditions. Mowing can also introduce non-native species through the use of contaminated equipment. Another disadvantage of mowing is that the duff or litter layer remains on the ground, preventing seeds from reaching the bare ground needed for germination. This thick litter layer can also provide heavy fuel loads increasing the risk of wildfires during dry periods. Although mowing provides some level of habitat management in pine savannahs, it is not a substitute for prescribed fire. Mowing can maintain succession, but may inhibit other functions of the system.

6.14.1.3.2 Removal of Exotics and Plantation Pines (2)

This management measure must be included in all measures for the restoration to be successful. This measure positively affects the percent cover by invasive or exotic species.

6.14.1.3.3 Fill Ditches (3)

This management measure must be included in all measures for the restoration to be successful. This measure positively affects the outflow of water. It measures the removal of water by ditches or drains.

6.14.1.3.4 Ecosystem Restoration Measures

These management measures were combined to create six measures. Each measure requires burning and mowing the project area in the initial year on construction and maintaining native savanna vegetation by either burning every three years or mowing every year, removing all exotics and plantation pine and maintaining their elimination over the project life, and filling all artificial ditches. The difference between each measure includes the number of acres restored and the method of maintaining vegetation over the life of the project.

Measures 1 and 2 consist of restoring the project areas north and south of the road: 385 acres. Measure 1 maintains vegetation by burning once every three years. Measure 2 maintains vegetation by mowing every year. Measures 3 and 4 consist of restoring only the project area north of the road: 151 acres. Measure 3 maintains vegetation by burning once every three years. Measure 4 maintains vegetation by mowing every year. Measures 5 and 6 consist of restoring only the project area south of the railroad: 234 acres. Measure 5 maintains vegetation by burning once every three years. Measure 6 maintains vegetation by mowing every year. Table 6.14-2 displays a description of each ecosystem restoration measure. Figure 6.14-2 shows the Dantzler restoration site.

Table 6.14-2.
Ecosystem Restoration Measures

Measure	Management Measures	Measure Description
0	No Action	No Action
1	1a + 2 +3	385 Acre Restoration Maintain by Burning
2	1b + 2 + 3	385 Acre Restoration Maintain by Mowing
3	1a + 2 +3	151 Acre Restoration Maintain by Burning
4	1b + 2 + 3	151 Acre Restoration Maintain by Mowing
5	1a + 2 +3	234 Acre Restoration Maintain by Burning
6	1b + 2 + 3	234 Acre Restoration Maintain by Mowing

Figure 6.14-2. Dantzler Restoration Site

6.14.1.4 Benefits

In order to restore this area to a Wet Pine Savannah habitat, the higher areas will be designated as Wet Pine Savannah. These areas have depression areas within them which will enable water to flow down to the depression areas; thus, holding water. The Wet Pine Savannah habitat will be restored with Wet Pine Flatwoods, such as Pinus elliotti, Morella cerifera, Llex glabra, Spartina patens and Panicum virgatum.

Many species of wildlife are indigenous to the Wet Pine Savannah habitat. Understory plant communities may contain wiregrass, sedges, orchids, American Chaff seed and rough-leaved loosestrife. Insectivorous plants that may be found include pitcher plants, bladderworts, venus flytrap, and sundews. Rare, threatened or endangered birds that may occur in these areas include Henslowe's sparrow, Bachman's sparrow, red-cockaded woodpecker, and Mississippi Sandhill Crane. This ecosystem may also benefit the Mississippi Gopher frog and in drier areas along ridges, the black pine snake and the gopher tortoise.

Benefits are measured in terms of Average Annual Functional Units (AAFU). The Hydrogeomorphic (HGM) approach was used to assess wetland function. A HGM assessment was performed in 2000 using the Regional Guidebook for Applying the HGM Approach to Assessing Wetland Functions of Wet Pine Flats on Mineral Soils in the Atlantic and Gulf Coastal Plains. Results from this assessment were used to establish baseline (current) conditions and, ultimately, to measure the functional unit benefits resulting from different restoration measures. Table 6.14-3 shows the AAFU net benefit

under each measure. The AAFU net benefit was calculated as the difference between the total functional units for the ecosystem restoration measure and the total functional units for the no action measure.

Table 6.14-3.
Summary of Benefits

Measure	Measure Description	AAFU Net Benefit
No Action	No Action	0
Measure 1	385 Acre Restoration Maintain by Burning	1,244
Measure 2	385 Acre Restoration Maintain by Mowing	943
Measure 3	151 Acre Restoration Maintain by Burning	488
Measure 4	151 Acre Restoration Maintain by Mowing	370
Measure 5	234 Acre Restoration Maintain by Burning	756
Measure 6	234 Acre Restoration Maintain by Mowing	573

6.14.1.5 Costs

A rough order magnitude (ROM) cost estimate was developed for the 385, 151, and 234 acres of restoration. It included the cost of filling ditches with 65,560, 30,560, and 36,000 cubic yards of material for $798,720, $366,720, and $432,000, respectively; burning 385, 151, and 234 acres of vegetation for $57,750, $22,650, and $35,100, respectively; mowing 385, 151, and 234 acres for $32,725, $12,835, and $19,890, respectively; removing roads and utilities for $275,000, $121,000, and $154,000; mobilizing and demobilizing for $40,000, $20,000, and $20,000, respectively; and miscellaneous site items for $90,000, $45,000, and $45,000, respectively. Total construction costs for the 385, 151, and 234 acres of restoration equaled $1,294,195, $588,205, and $882,488. A contingency cost of 25 percent and lands and damages costs of $25,000 were added to the construction cost. Then, Planning, Engineering and Design (PED) costs of 8 percent and a Construction Management cost of 6 percent were added for a total first cost of construction of $1,881,000, $870,000, and $1,039,000.

For each measure, these first costs of construction are presented in Table 6.14-4 at October 2007 price levels along with the Interest During Construction (IDC), investment cost (first cost plus IDC), Average Annual Investment Cost (AAIC), Average Annual Operations and Maintenance (AAO&M) cost and, ultimately, the Average Annual Costs (AAC).

Investment cost, O&M cost and AAC for Measure 1 are $1,922,000, $1,328,000, and $129,000, respectively. The investment cost, O&M cost and AAC for Measure 2 are $1,922,000, $2,303,000, and $150,000, respectively. The investment cost, O&M cost and AAC for Measure 3 are $889,000, $528,000, and $58,000, respectively. The investment cost, O&M cost and AAC for Measure 4 are $889,000, $931,000, and $67,000, respectively. The investment cost, O&M cost and AAC for Measure 5 are $1,039,000, $816,000, and $73,000, respectively. The investment cost, O&M cost and AAC for Measure 6 are $1,039,000, $1,421,000, and $86,000, respectively.

Table 6.14-4.
Summary of Costs by Measure for Dantzler Area

Measure	Measure Description	Implement-ation Cost (FY-08)	IDC	Investment Cost	AAIC	AAO&M	AAC
0	No Action	$0	$0	$0	$0	$0	$0
1	879 Acre Restoration Maintain by Burning	$1,880,000	$41,000	$1,922,000	$103,000	$26,000	$129,000
2	879 Acre Restoration Maintain by Mowing	$1,880,000	$41,000	$1,922,000	$103,000	$47,000	$150,000
3	689 Acre Restoration Maintain by Burning	$870,000	$19,000	$889,000	$48,000	$10,000	$58,000
4	689 Acre Restoration Maintain by Mowing	$870,000	$19,000	$889,000	$48,000	$19,000	$67,000
5	190 Acre Restoration Maintain by Burning	$1,040,000	$23,000	$1,062,000	$57,000	$16,000	$73,000
6	190 Acre Restoration Maintain by Mowing	$1,040,000	$23,000	$1,062,000	$57,000	$29,000	$86,000

Note: Numbers are rounded to the nearest thousand dollars.

First cost of construction is used along with the duration of 12 months of construction and a discount rate of 4.875 percent to calculate Interest During Construction (IDC). The sum of the first cost of construction and IDC cost equals the investment cost. This cost is amortized at the FY 2007 federal discount rate of 4.875 percent over a 50-year economic period of analysis to calculate the Average Annual Investment Cost (AAIC). Average Annual O&M (AAO&M) costs for burning once every three years or mowing every year were present valued and amortized at an interest rate of 4.875 percent over a 50-year economic period of analysis. The sum of the AAIC and AAO&M cost equals the Average Annual Costs (AAC).

6.14.2 Comparison of Measures

Table 6.14-5 displays all measures with their respective AAC and AAFU.

Table 6.14-5.
All Measures: AAC and AAFU

Measure	AAC	AAFU
No Action	$0	0
1	$129,000	1,244
2	$150,000	943
3	$20,000	488
4	$29,000	370
5	$60,000	756
6	$73,000	573

Note: The AAC values are rounded to the nearest thousand dollars.

In order to determine the cost effectiveness of each measure, the list of measures is reordered so that they are listed in increasing order of their outputs (AAFU). This list is shown in Table 6.14-6.

Table 6.14-6.
All Measures Arrayed by Increasing Output

Measure	AAC	AAFU
No Action	$0	0
4	$29,000	370
3	$20,000	488
6	$73,000	573
5	$60,000	756
2	$150,000	943
1	$129,000	1,244

Note: The AAC values are rounded to the nearest thousand dollars.

To determine if a measure is cost effective, economically inefficient measures must first be identified and eliminated. An economically inefficient measure is a measure that cost more for the same level of benefit. No measures are eliminated for the reason of economic inefficiency because each measure produces a different level of benefit.

Lastly, economically ineffective measures are identified and eliminated to determine which measures are cost effective. An economically ineffective measure is a measure that cost more or the same as a subsequent measure but produces less benefit than that subsequent measure. As shown in Table 6.14-7, the three shaded measures, 2, 4, and 6 were eliminated because they produced less benefit at greater cost than a subsequent measure. For example, Measure 4 produces 370 AAFU at an AAC of $29,000 while Measure 3 produces 488 AAFU at an AAC $20,000. Measure 4 produces less AAFU at a greater cost than Measure 3. Therefore, Measure 4 is eliminated. As shown in table 6.14-8 and plotted in figure 6.14-3, the cost effective measures are Measure 1 (385 acres of restoration maintained by burning), Measure 3 (151 acres of restoration maintained by burning) and Measure 5 (234 acres of restoration maintained by burning).

Table 6.14-7.
Elimination of Economically Ineffective Measures

Measure	Measure Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
4	151 Acre Restoration Maintain by Mowing	$29,000	370	No
3	151 Acre Restoration Maintain by Burning	$20,000	488	Yes
6	234 Acre Restoration Maintain by Mowing	$73,000	573	No
5	234 Acre Restoration Maintain by Burning	$60,000	756	Yes
2	385 Acre Restoration Maintain by Mowing	$150,000	943	No
1	385 Acre Restoration Maintain by Burning	$129,000	1,244	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

Table 6.14-8.
Cost Effective Measures for Dantzler Area

Measure	Measure Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
3	151 Acre Restoration Maintain by Burning	$20,000	488	Yes
5	234 Acre Restoration Maintain by Burning	$60,000	756	Yes
1	385 Acre Restoration Maintain by Burning	$129,000	1,244	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

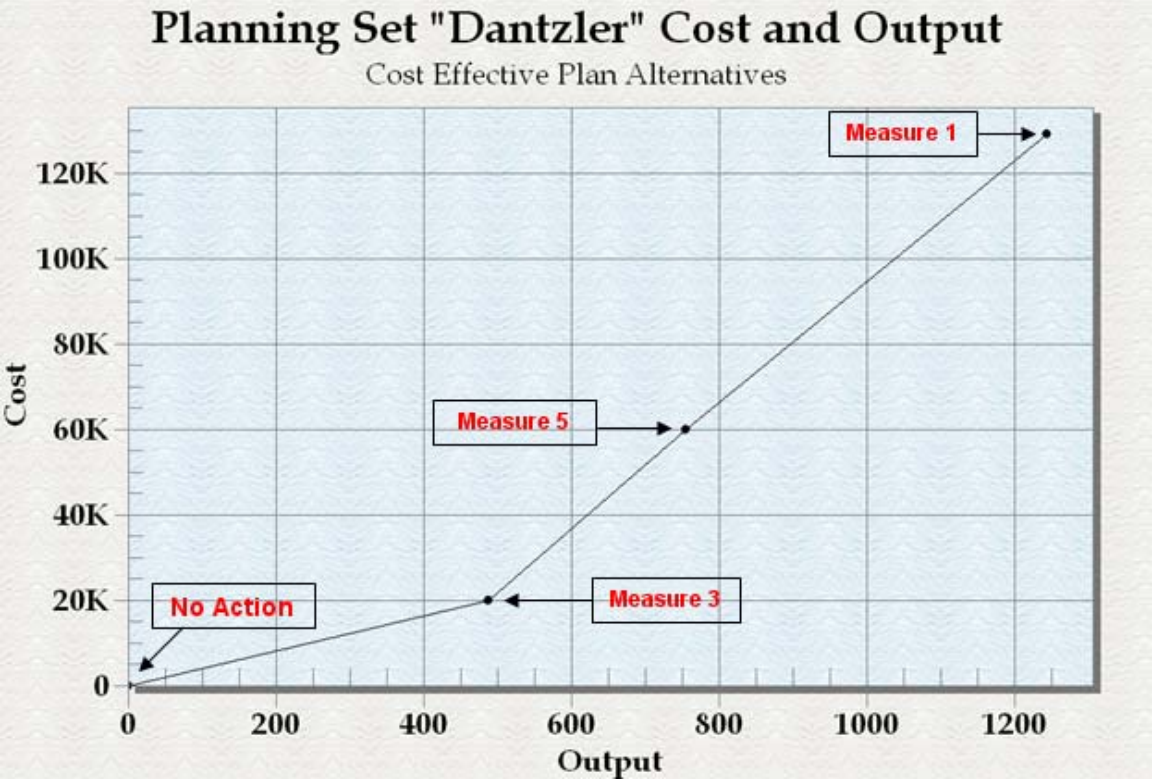

Figure 6.14-3. Display of Cost Effective Alternatives for the Dantzler Area

6.14.3 Regional Economic Development (RED) Benefits

6.14.3.1 Socioeconomic Impacts using the Economic Impact Forecast System

The purpose of this section is to show the economic impact of the cost effective alternatives on business (sale volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Jackson County, Mississippi. The expenditures for the alternatives are estimated to be $1,900,000 for Alternative 1, $1,040,000 for Alternative 3, $870,000 for Alternative 5. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $484,000 for Alternative 1, $186,000 for Alternative 3, and

$298,000 for Alternative 5 (assuming a 50 year period of analysis and an interest rate of 4.875 percent).

6.14.4 Summary Explanation of the EIFS Model Output

The outputs shown in this section are based on the following input from the proposed project alternatives. EIFS model inputs and outputs are shown in tables 6.14-9 through 6.14-12. The inputs are as follows:

Table 6.14-9.
EIFS Model Implementation Inputs for the Dantzler Ecosystem

	No Action	Alternative 1	Alternative 3	Alternative 5
Region of Influence (ROI)	Jackson County	Jackson County	Jackson County	Jackson County
Change in Local Expenditures	$0	$1,900,000	$1,040,000	$870,000

Based of the given inputs the outputs are as follows:

Table 6.14-10.
EIFS Model Implementation Outputs for the Dantzler Ecosystem

	No Action	Alternative 1	Alternative 3	Alternative 5
Direct Sales Volume	$0	$1,900,000	$1,040,000	$870,000
Induced Sales Volume	$0	$2,128,000	$1,164,800	$974,400
Total Sales Volume	$0	$4,028,000	$2,204,800	$1,844,400
Direct Income	$0	$370,549	$202,827	$169,672
Induced Income	$0	$415,014	$227,166	$190,033

6.15 Franklin Ecosystem Restoration Measures

This section describes the evaluation of ecosystem restoration measures at the Franklin Creek area that is located within planning sub-unit 53, which is part of planning unit three. The total area includes 149 acres of land that was acquired during the interim phase of the MsCIP. This area was selected for ecosystem restoration using the Decision Support System, a GIS based model created by the Corps' Engineer Research and Development Center (ERDC). For more details on the selection process for ecosystem restoration sites see the Economic Appendix. Figure 6.15-1 shows the location of the Franklin Creek area.

6.15.1 Formulation of Alternatives

6.15.1.1 Assumptions

In order for the Franklin Creek site to undergo ecosystem restoration, it is assumed that all of the property is being acquired under the Mississippi Coastal Improvements Program Interim Projects.

6.15.1.2 Objectives

The following objectives were developed for ecosystem restoration:

- Restore native vegetation
- Restore natural fire regime
- Restore natural hydrology
- Restore fish and wildlife habitat
- Provide storm water storage protection

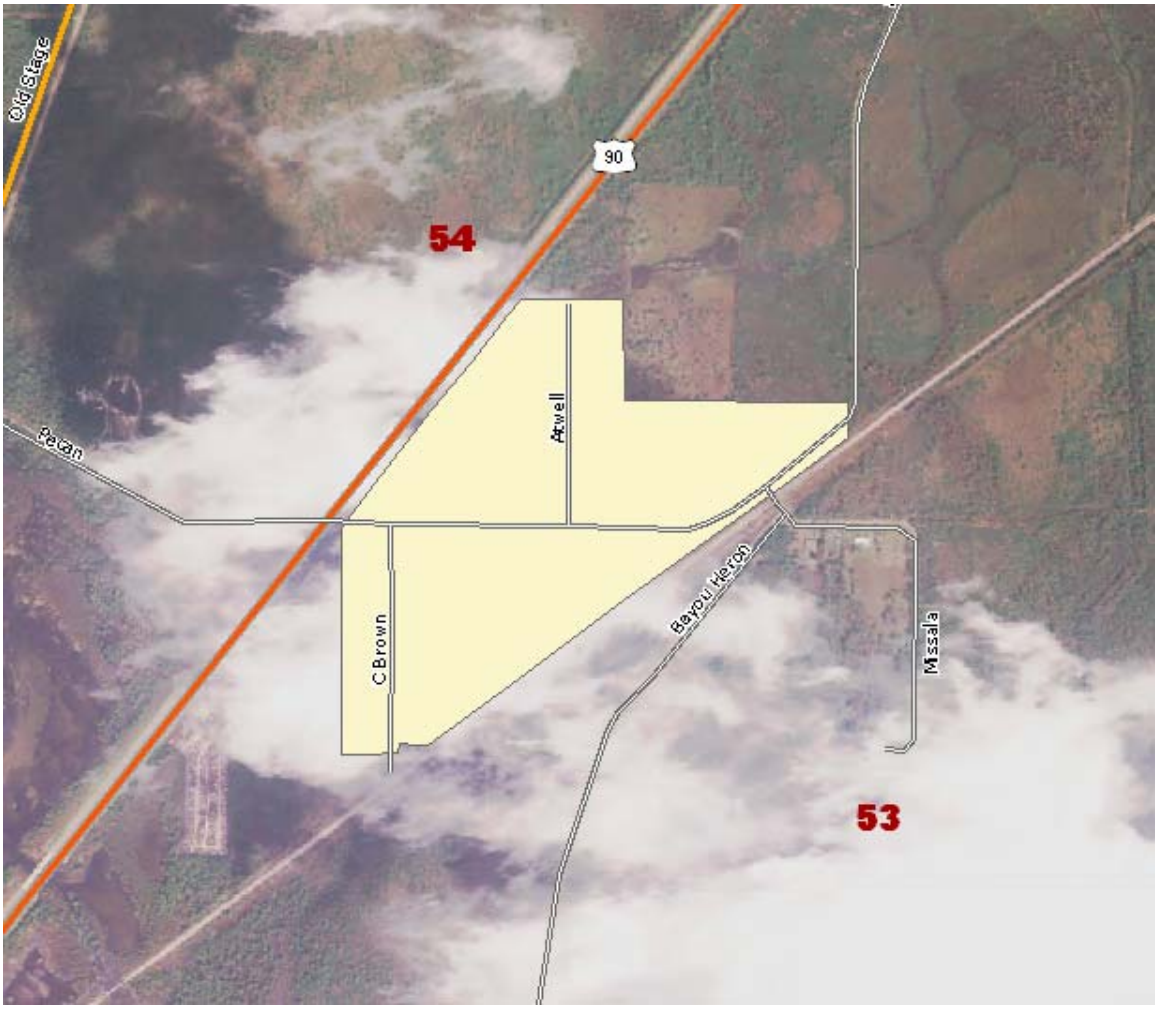

Figure 6.15-1. Franklin Creek Restoration Area.

6.15.1.3 Ecosystem Restoration Management Measures

Proposed restoration management measures are listed in table 6.15-1. Narrative descriptions of each management measure follow this table.

Table 6.15-1
Ecosystem Restoration Management Measures

Management Measure	Description
No Action	No Action
1	Fill Artificial Ditches
2 *a* *b*	Maintain Native Savannah Vegetation *By Burning Every 3Years* *By Mowing Annually*
3	Excavate & Remove Roadbeds & Fill
4	Add Culverts

6.15.1.4 Fill Ditches (1)

This management measure must be included in all alternatives for the restoration to be successful. This measure positively affects the outflow of water. It measures the removal of water by ditches or drains.

6.15.1.5 Maintain Native Savannah Vegetation (2)

This management measure must be included in all alternatives for the restoration to be successful. There are two methods that will be analyzed for maintaining vegetation: (a) burning and (b) mowing. Fire benefits this ecosystem in many different ways. It creates a bare seedbed for pine seedlings and other fire dependent plants, reduces fuel loads and recycles nutrients. Periodic burning promotes early successional plants that are important to many species of wildlife indigenous to this ecosystem. Many of the plant species found in this ecosystem are fire dependent; for example, the federally endangered American Chaff seed flowers almost exclusively after a fire. It has been reduced to a fraction of its original range due to fire suppression and habitat destruction. Fire suppression is mainly due to liability issues and fear of litigation.

Mowing is a mechanical alternative that many land managers use to maintain early successional habitats. Although it is successful to some extent, it fails to provide all the necessary components that come from prescribed fire. This method also has a negative effect. Mowing requires the use of heavy equipment in sensitive areas. Tractors can create ruts in saturated soils, creating hydrologic problems and micro site conditions. Mowing can also introduce non-native species through the use of contaminated equipment. Another disadvantage of mowing is that the duff or litter layer remains on the ground, preventing seeds from reaching the bare ground needed for germination. This thick litter layer can also provide heavy fuel loads increasing the risk of wildfires during dry periods. Although mowing provides some level of habitat management in pine savannahs, it is not a substitute for prescribed fire. Mowing can maintain succession, but may inhibit other functions of the system.

6.15.1.6 Excavate and Remove Existing Roadbeds and Fill (3)

This management measure must be included in all alternatives for the restoration to be successful. This measure affects the surface water storage. An ecological improvement would occur where existing roadbeds and fill are removed.

6.15.1.7 Add Culverts (4)

This measure increases the hydrologic connection between the two existing wetland areas separated by the elevated railway. The wetlands are primarily precipitation driven resulting in sheet flow drainage. Additional culverts will result in increased sheet flow drainage reducing standing surface water in the northern wetland area.

6.15.1.8 Ecosystem Restoration Alternatives

These management measures were combined to create four alternatives. Each alternative requires filling in ditches, maintaining native savannah vegetation by burning and mowing the project area in the initial year of construction with followed-up maintenance throughout the life of the project with either burning every 3 years or mowing every year, and excavating and removing existing roadbeds and any additional fill. Restoring the north and south acres together also includes adding culverts to increase hydrologic connectivity whereas restoring only the south portion does not include the culvert measure. Otherwise, the difference between each alternative includes the number of acres restored and/or the method of maintaining vegetation over the life of the project. Restoring only the north portion was not considered as an alternative since it would make the ecology worse off.

Alternatives 1 and 2 consist of restoring the project areas north and south of the railway: 149 acres. Alternative 1 maintains vegetation by burning once every three years. Alternative 2 maintains vegetation by mowing every year. Alternatives 3 and 4 consist of restoring only the project area south of the railway: 56 acres. Alternative 3 maintains vegetation by burning once every three years. Alternative 4 maintains vegetation by mowing every year. Table 6.15-2 displays a description of each ecosystem restoration alternative. Figure 6.15-2 shows the Franklin Creek restoration site divided by the railroad into the north (A) and south (B) acreages.

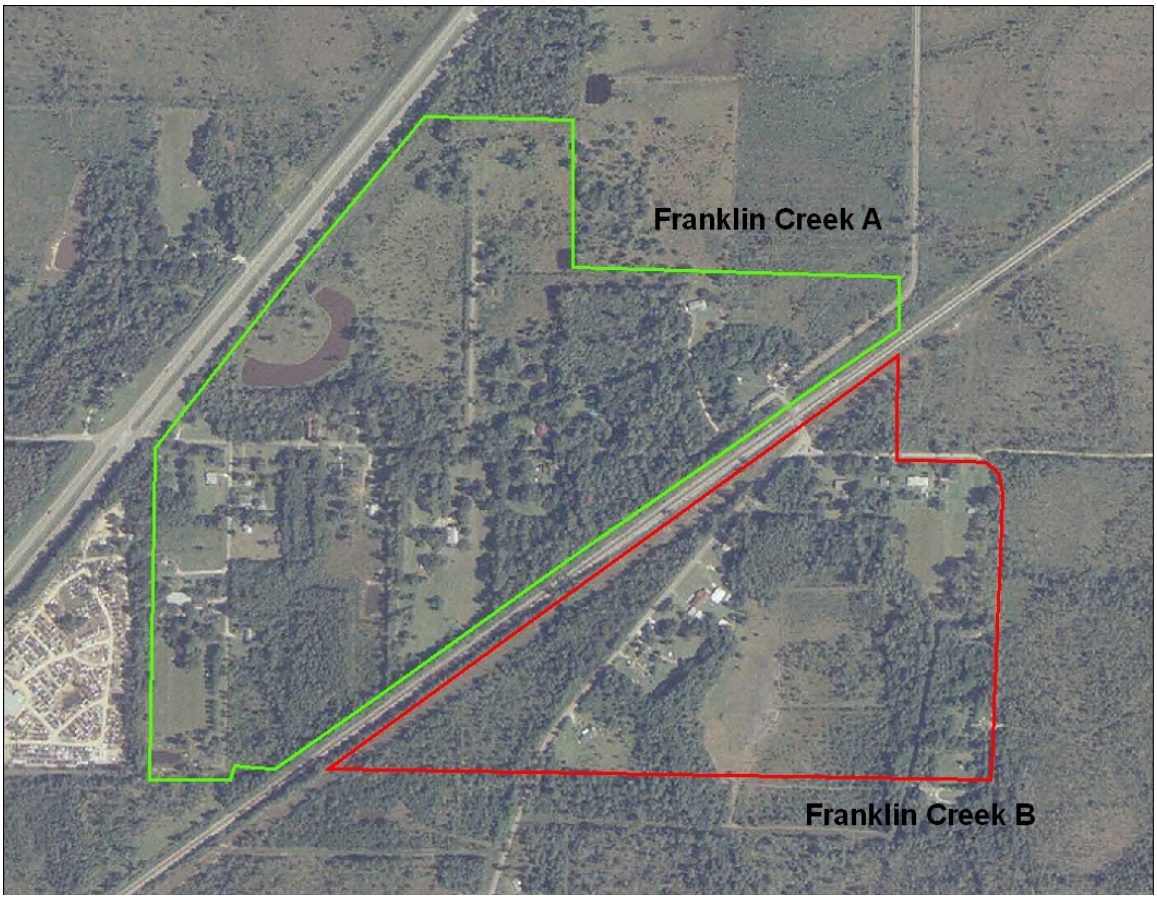

Figure 6.15-2. Franklin Creek Restoration Site

Table 6.15-2.
Ecosystem Restoration Alternatives

Alternative	Management Measures	Alternative Description
0	No Action	No Action
1	1 + 2a + 3 + 4	149 Acre Restoration Maintain by Burning
2	1 + 2b + 3 + 4	149 Acre Restoration Maintain by Mowing
3	1 + 2a +3	56 Acre Restoration Maintain by Burning
4	1 + 2b + 3	56 Acre Restoration Maintain by Mowing

6.15.1.9 Benefits

In order to restore this area to a Wet Pine Savannah habitat, the higher areas will be designated as Wet Pine Savannah. These areas have depression areas within them which will enable water to flow down to the depression areas; thus, holding water. The Wet Pine Savannah habitat will be restored with Wet Pine Flatwoods, such as Pinus elliotti, Morella cerifera, Ilex glabra, Spartina patens and Panicum virgatum.

Many species of wildlife are indigenous to the Wet Pine Savannah habitat. Understory plant communities may contain wiregrass, sedges, orchids, American Chaff seed and rough-leaved loosestrife. Insectivorous plants that may be found include pitcher plants, bladderworts, venus flytrap, and sundews. Rare, threatened or endangered birds that may occur in these areas include Henslowe's sparrow, Bachman's sparrow, red-cockaded woodpecker, and Mississippi Sandhill Crane. This ecosystem may also benefit the Mississippi Gopher frog and in drier areas along ridges, the black pine snake and the gopher tortoise.

Benefits are measured in terms of Average Annual Functional Units (AAFU). The Hydrogeomorphic (HGM) approach was used to assess wetland function. A HGM assessment was performed in 2000 using the Regional Guidebook for Applying the HGM Approach to Assessing Wetland Functions of Wet Pine Flats on Mineral Soils in the Atlantic and Gulf Coastal Plains. Results from this assessment were used to establish baseline (current) conditions and, ultimately, to measure the functional unit benefits resulting from different restoration alternatives. Table 6.15-3 shows the AAFU net benefit under each alternative. The AAFU net benefit was calculated as the difference between the total functional units for the ecosystem restoration alternative and the total functional units for the no action alternative.

Table 6.15-3.
Summary of Benefits

Alternative	Alternative Description	AAFU Net Benefit
No Action (alternatives 1-2)	No Action (149 acres)	0
No Action (alternatives 3-4)	No Action (56 acres)	0
Alternative 1	149 Acre Restoration Maintain by Burning	516
Alternative 2	149 Acre Restoration Maintain by Mowing	399
Alternative 3	56 Acre Restoration Maintain by Burning	194
Alternative 4	56 Acre Restoration Maintain by Mowing	150

6.15.1.10 Costs

A rough order magnitude (ROM) cost estimate was developed for the 149 acres of restoration represented in Alternatives 1 and 2. The first costs for Alternatives 1 and 2 are estimated at $1,634,000. First costs include construction, contingency, lands and damages, PED, and construction management costs. Investment cost (first cost plus IDC) for Alternatives 1 and 2 are estimated at $1,670,000. The equivalent average annual cost (AAC), which includes AAC of investment of $90,000 and O&M of $11,000 and $19,000, for Alternatives 1 and 2 are $101,000 and $109,000, respectively. The first costs for Alternatives 3 and 4 representing 56 acres of restoration south of the railway are estimated at $548,000. Investment cost (first cost plus IDC) for Alternatives 1 and 2 are estimated at $560,000. The AAC, which includes AAC of investment of $30,000 and

O&M of $4,000 and $7,000, respectively, for Alternatives 3 and 4 are $34,000 and $37,000, respectively.

For each alternative, first costs of construction, Interest During Construction (IDC), total investment cost, Average Annual Investment Cost (AAIC), Average Annual Operations and Maintenance (AAO&M) cost and, ultimately, the Average Annual Costs (AAC) are presented in table 6.15-4 at October 2007 price levels.

Table 6.15-4.
Summary of Costs by Measure for Franklin Creek

Alternative	Alternative Description	Implement-ation Cost (FY-08)	IDC	Investment Cost	AAIC	AAO&M	AAC
0	No Action	$0	$0	$0	$0	$0	$0
1	149 Acre Restoration Maintain by Burning	$1,630,000	$36,000	$1,670,000	$90,000	$11,000	$101,000
2	149 Acre Restoration Maintain by Mowing	$1,630,000	$36,000	$1,670,000	$90,000	$19,000	$109,000
3	56 Acre Restoration Maintain by Burning	$550,000	$12,000	$560,000	$30,000	$4,000	$34,000
4	56 Acre Restoration Maintain by Mowing	$550,000	$12,000	$560,000	$30,000	$7,000	$37,000

Note: Values are rounded to the nearest thousand dollars.

First cost of construction is used along with the duration of 12 months of construction and a discount rate of 4.875 percent to calculate Interest During Construction (IDC). The sum of the first cost of construction and IDC cost equals the investment cost. This cost is amortized at the FY 2007 federal discount rate of 4.875 percent over a 50-year economic period of analysis to calculate the Average Annual Investment Cost (AAIC). Average Annual O&M (AAO&M) costs for burning once every three years or mowing every year were present valued and amortized at an interest rate of 4.875 percent over a 50-year economic period of analysis. The sum of the AAIC and AAO&M cost equals the Average Annual Costs (AAC).

6.15.2 Comparison of Alternatives

Table 6.15-5 displays all alternatives with their respective AAC and AAFU.

Table 6.15-5.
All Alternatives: AAC and AAFU

Alternative	AAC	AAFU
No Action	$0	0
1	$101,000	516
2	$109,000	399
3	$34,000	194
4	$37,000	150

Note: The AAC values are rounded to the nearest thousand dollars.

In order to determine the cost effectiveness of each alternative, the list of alternatives is reordered so that they are listed in increasing order of their outputs (AAFU). This list is shown in table 6.15-6.

Table 6.15-6.
All Alternatives Arrayed by Increasing Output

Alternative	AAC	AAFU
No Action	$0	0
4	$37,000	150
3	$34,000	194
2	$109,000	399
1	$101,000	516

Note: The AAC values are rounded to the nearest thousand dollars.

To determine if an alternative is cost effective, economically inefficient alternatives must first be identified and eliminated. An economically inefficient alternative is an alternative that cost more for the same level of benefit. No alternatives are eliminated for the reason of economic inefficiency because each alternative produces a different level of benefit.

Lastly, economically ineffective alternatives are identified and eliminated to determine which alternatives are cost effective. An economically ineffective alternative is an alternative that costs more or the same as a subsequent alternative but produces less benefit than that subsequent alternative. As shown in table 6.15-7, the two shaded alternatives 4 and 2 were eliminated because they produced less benefit at greater cost than a subsequent alternative. For example, Alternative 4 produces 150 AAFU at an AAC of $37,000 while Alternative 3 produces 194 AAFU at an AAC $34,000. Alternative 4 produces less AAFU at a greater cost than Alternative 3. Therefore, Alternative 4 is eliminated. As shown in table 6.15-8 and plotted in figure 6.15-3, the cost effective alternatives are Alternative 3 (56 acres of restoration maintained by burning) and Alternative 1 (149 acres of restoration maintained by burning).

Table 6.15-7.
Elimination of Economically Ineffective Alternatives

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
4	56 Acre Restoration Maintain by Mowing	$37,000	150	No
3	56 Acre Restoration Maintain by Burning	$34,000	194	Yes
2	149 Acre Restoration Maintain by Mowing	$109,000	399	No
1	149 Acre Restoration Maintain by Burning	$101,000	516	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

Table 6.15-8.
Cost Effective Alternatives for Franklin Creek Area

Alternative	Alternative Description	AAC	AAFUs	Cost Effective?
No Action	No Action	$0	0	Yes
3	56 Acre Restoration Maintain by Burning	$34,000	194	Yes
1	149 Acre Restoration Maintain by Burning	$101,000	516	Yes

Note: The AAC values are rounded to the nearest thousand dollars.

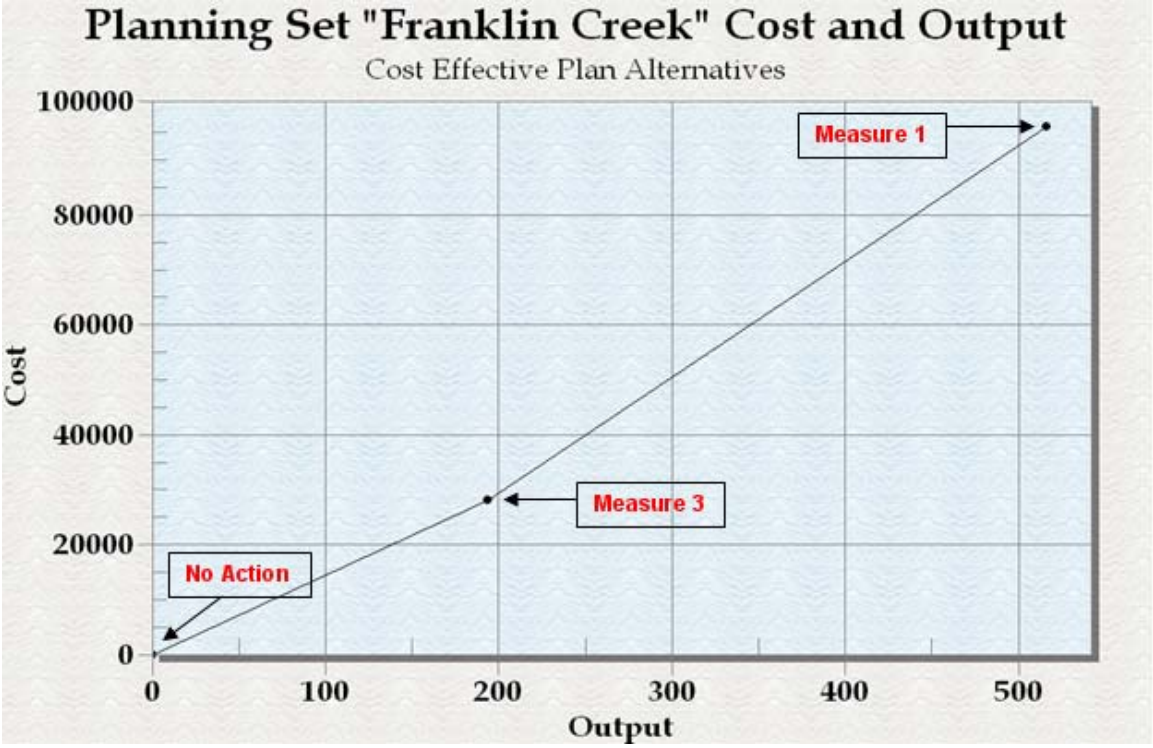

Figure 6.15-3. Display of Cost Effective Alternatives for the Franklin Creek Area

6.15.3 Regional Economic Development (RED) Benefits

6.15.3.1 Summary of Socioeconomic Impacts using the Economic Impact Forecast System

The purpose of this analysis is to show the economic impact of the cost effective alternatives on business (sale volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Jackson County, Mississippi. The expenditures for the alternatives are estimated to be $960,000 for Alternative 1, $1,530,000 for Alternative 3. Moreover, the total present worth of the operation and maintenance (O&M) expenditures are estimated to be $205,000 for Alternative 1 and $74,000 for Alternative 3 (assuming a 50 year period of analysis and an interest rate of 4.875 percent).

The outputs shown in this section are based on the following input from the proposed project measures. The inputs and outputs are shown in tables 6.15-9 through 6.15-12. The inputs are as follows:

Table 6.15-9.
EIFS Model Implementation Inputs for Franklin Creek Ecosystem

	No Action	Alternative 1	Alternative 3
Region of Influence (ROI)	Jackson County	Jackson County	Jackson County
Change in Local Expenditures	$0	$1,630,000	$550,000

Based of the given inputs the outputs are as follows:

6.16 Evaluation of Inland Barrier and Surge Barrier Flood Damage Reduction Measures

6.16.1 General

The Inland barrier and surge barrier area is located in all three planning units just north of the roadways that run parallel to the beach. These areas are denoted by the inland zone planning area. In planning unit one, the inland barrier area includes planning sub-units one, two, seven, thirty-seven, and thirty-eight; in planning unit two, planning sub-units eight, eleven, twelve, fourteen, sixteen, seventeen, twenty, thirty-nine, forty, forty-seven, forty-eight, and fifty; and in planning unit three the planning sub-units are twenty-one, twenty-three, forty-one, forty-six, and forty-nine.

6.16.2 Historic (Pre-Hurricane Katrina) Conditions

The pre-Hurricane Katrina conditions for planning sub-units three and four in planning unit one represented a mostly residential community as shown in Table 6.16-1. The areas in planning unit one included 35,770 tax parcels, of which 17,914 contained an asset with some economic value and 17,856, were vacant land. Of the 17,914 parcels that contain assets, 13,961 were residential one-story, 763 were residential two-story, 463 were mobile homes, 2,236 were commercial, and 491 were municipal. The areas in planning unit two included 76,487 tax parcels, of which 48,962 contained an asset with some economic value and 27,525 were vacant land. Of the 48,962 parcels that contain assets, 40,456 were residential one-story, 1,594 were residential two-story, 2,487 were mobile homes, 4,136 were commercial, and 289 were municipal. The areas in planning unit three included 21,353 tax parcels, of which 14,575 contained an asset with some economic value and 6,778 were vacant land. Of the 14,575 parcels that contain assets, 12,551 were residential one-story, 311 were residential two-story, 828 were mobile homes, 789 were commercial, and 96 were municipal.

Table 6.16-1.
Pre-Hurricane Katrina Estimate of Structures for Inland Zone Area

	Planning Unit One	Planning Unit Two	Planning Unit Three	
Asset Categories	**Assets by Category**	**Assets by Category**	**Assets by Category**	**Total**
Residential	14,724	42,050	12,862	**69,636**
Mobile Homes	463	2,487	828	**3,778**
Commercial	2,236	4,136	789	**7,161**
Municipal	491	289	96	**876**
Vacant Land	17,856	27,525	6,778	**52,159**
Total	**35,770**	**76,487**	**21,353**	**133,610**

Figure 6.16-1 denotes the various zones and shows the inland zone in green. Figures 6.16-2 shows the planning sub-units of the area by planning unit.

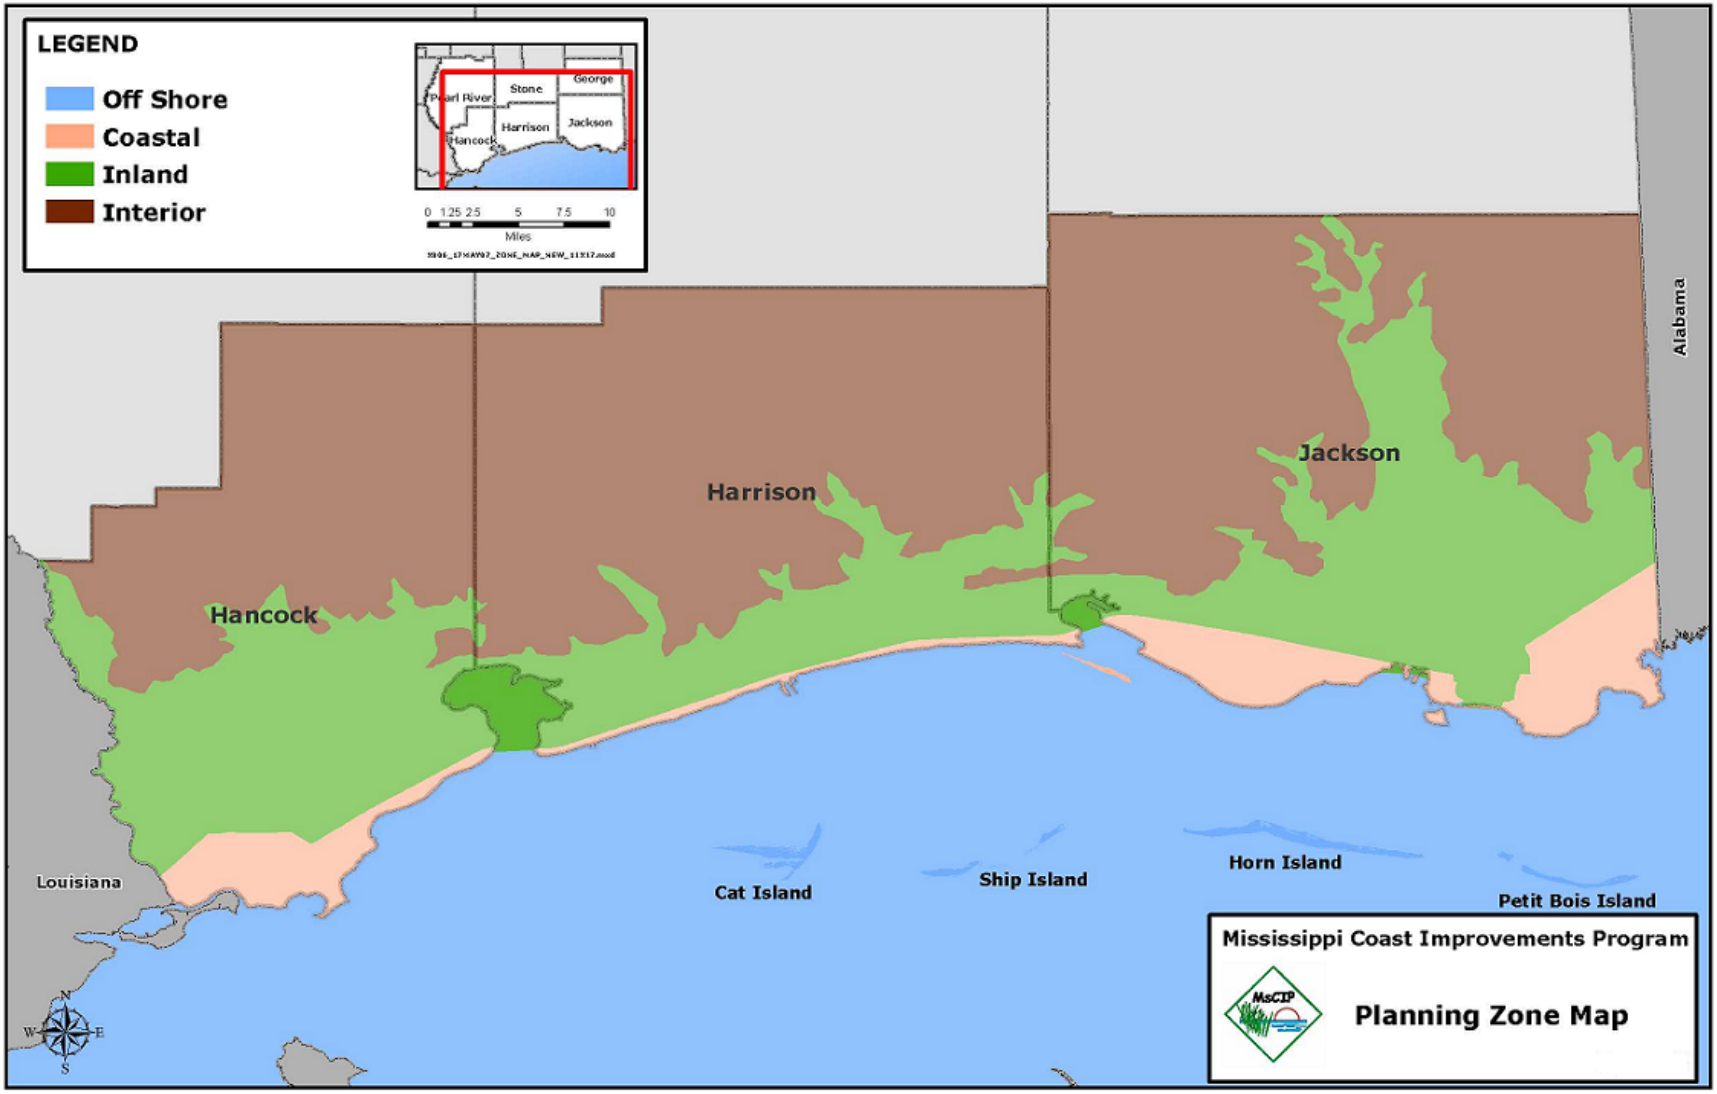

Figure 6.16-1. Planning Zones – Impacted area is the inland zone

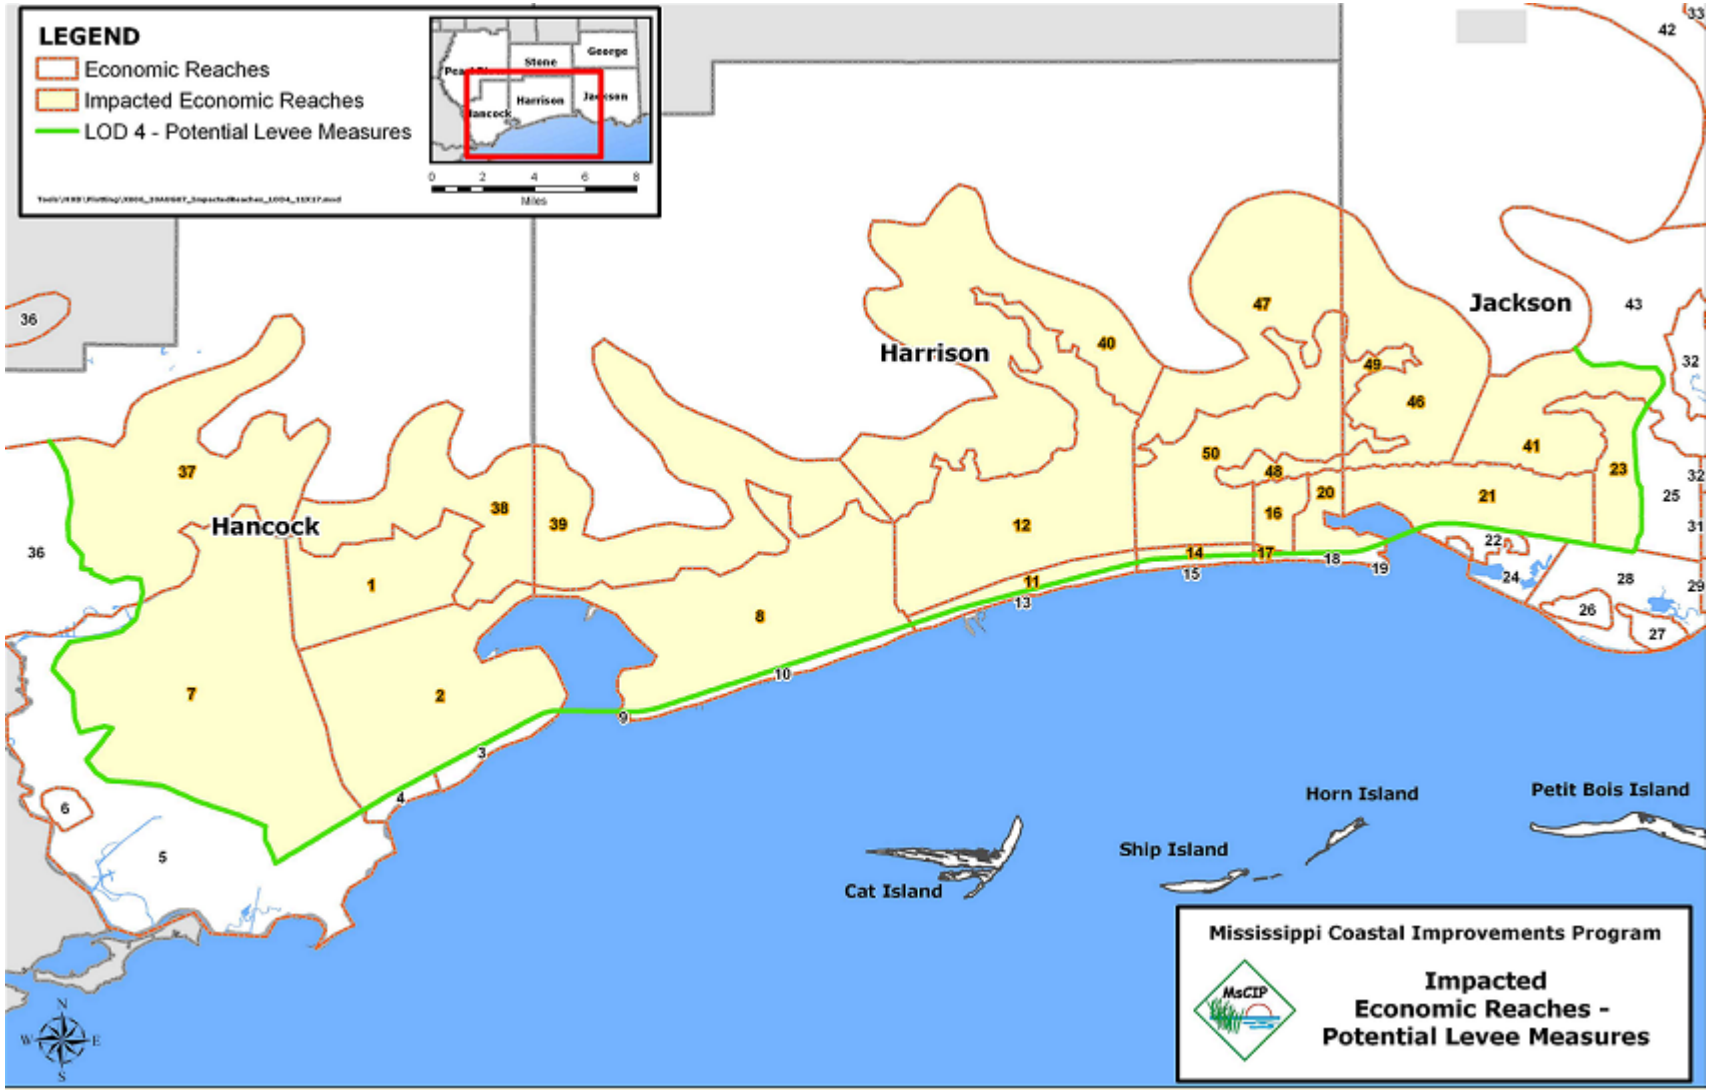

Figure 6.16-2 Planning sub-units in Inland Area for Planning Units One, Two, and Three

6.16.2.1 Existing (Post-Hurricane Katrina) Conditions

Hurricane Katrina made its Mississippi landfall just west of planning sub-units three and four. Damage from the surge was devastating across the three planning units. In the inland barrier impact area, it is estimated that 12,857 structures sustained significant damage (50-percent or more). Of those, 5,610 were destroyed in planning unit one, 6,850 in planning unit two, and 397 were destroyed in planning unit three. Table 6.16-2 displays the destroyed structures by category and by planning unit for these areas.

Table 6.16-2.
Destroyed Structures by Category and Planning Unit

	Planning Unit One	Planning Unit Two	Planning Unit Three	
Asset Categories	**Assets by Category**	**Assets by Category**	**Assets by Category**	**Total**
Residential	5,213	6,115	349	**11,677**
Mobile Homes	33	60	10	**103**
Commercial	311	648	38	**997**
Municipal	53	27	0	**80**
Total	**5,610**	**6,850**	**397**	**12,857**

6.16.3 Opportunities

The following opportunities were identified for this area:

- Hurricane storm damage reduction or remediation.

6.16.4 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs.
- Price levels are FY-08, unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs for initial screening.
- Full redevelopment of the area will take place by the base year 2012.

6.16.5 Measures

Initially, a comprehensive list of measures was identified for flood damage reduction purposes for planning unit one. This list was screened and vetted for engineering and environmental feasibility and for policy compliance. The MsCIP Comprehensive Main Report and the Engineering and Environmental Appendices contain a detailed description of the measures that were initially screened.

Several potential measures were carried forward for this area for the purpose of flood damage reduction. These measures include both structural features and nonstructural actions. The measures evaluated for economic benefits include:

- Measure A - LOD-4, Inland Barrier and Surge Barrier at 20.0-feet NAVD88 Elevation

This measure will consist of an elevation 20.0-feet NAVD88 earthen levee construction in planning unit one along an alignment that extends southward from the same ground surface elevation as the levee along the last watershed divide before entering the Pearl River basin and then turn eastward and extend along the south side of the CSX railroad track to the Bay St. Louis Surge Barrier. An elevation 20.0-feet NAVD88 surge barrier will extend across the mouth of St. Louis Bay from the western shore in Hancock County to the eastern shore in Harrison County. The structure will be located just south of the railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. The earthen levee will then continue in planning unit two along an alignment that extends eastward from the Bay St. Louis Surge Barrier along the south side of the CSX railroad track to the Biloxi Bay Surge Barrier.

A second elevation 20.0-feet NAVD88 surge barrier will extend across the mouth of Biloxi Bay from the western shore in Harrison County to the eastern shore in Jackson County. The structure will be located just south of the existing railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. In planning unit three, the earthen levee construction will continue along an alignment that extends eastward from the Biloxi Bay Surge Barrier along the south side of the CSX railroad track to the last watershed divide before entering the Pascagoula River basin. At the watershed divide, the alignment will follow the divide northward until it intersects the same ground surface elevation as the levee. This system will include interior drainage, pumping stations, and required road crossings. All required maintenance for the surge barrier facilities will be included.

- Measure B – LOD-4, Inland Barrier and Surge Barrier at 30.0-feet NAVD88 Elevation

This measure will consist of an elevation 30.0-feet NAVD88 earthen levee construction in planning unit one along an alignment that extends southward from the same ground surface elevation as the levee along the last watershed divide before entering the Pearl River basin and then turn eastward and extend along the south side of the CSX railroad track to the Bay St. Louis Surge Barrier. An elevation 30.0-feet NAVD88 surge barrier will extend across the mouth of St. Louis Bay from the western shore in Hancock County to the eastern shore in Harrison County. The structure will be located just south of the railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. The earthen levee will then continue in planning unit two along an alignment that extends eastward from the Bay St. Louis Surge Barrier along the south side of the CSX railroad track to the Biloxi Bay Surge Barrier.

A second elevation 30.0-feet NAVD88 surge barrier will extend across the mouth of Biloxi Bay from the western shore in Harrison County to the eastern shore in Jackson County. The structure will be located just south of the existing railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. In planning unit three, the earthen levee construction will continue along an alignment that extends eastward from the Biloxi Bay Surge Barrier along the south side of the CSX railroad track to the last watershed divide before entering the Pascagoula River basin. At the watershed divide, the alignment will follow the divide northward until it intersects the same ground surface elevation as the levee. This system will include interior drainage, pumping stations, and required road crossings. All required maintenance for the surge barrier facilities will be included.

- Measure C - LOD-4, Inland Barrier and Surge Barrier at 40.0-feet NAVD88 Elevation

This measure will consist of an elevation 40.0-feet NAVD88 earthen levee construction in planning unit one along an alignment that extends southward from the same ground surface elevation as the levee along the last watershed divide before entering the Pearl River basin and then turn eastward and extend along the south side of the CSX railroad track to the Bay St. Louis Surge Barrier. An elevation 40.0-feet NAVD88 surge barrier will extend across the mouth of St. Louis Bay from the western shore in Hancock County to the eastern shore in Harrison County. The structure will be located just south of the railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. The earthen levee will then continue in planning unit two along an alignment that extends eastward from the Bay St. Louis Surge Barrier along the south side of the CSX railroad track to the Biloxi Bay Surge Barrier.

A second elevation 40.0-feet NAVD88 surge barrier will extend across the mouth of Biloxi Bay from the western shore in Harrison County to the eastern shore in Jackson County. The structure will be located just south of the existing railway bridge. The barrier will consist of abutments extending from each shore with rising sector gates spanning most of the distance. The abutments will include gated culverts to provide proper circulation and tidal exchange. In planning unit three, the earthen levee construction will continue along an alignment that extends eastward from the Biloxi Bay Surge Barrier along the south side of the CSX railroad track to the last watershed divide before entering the Pascagoula River basin. At the watershed divide, the alignment will follow the divide northward until it intersects the same ground surface elevation as the levee. This system will include interior drainage, pumping stations, and required road crossings. All required maintenance for the surge barrier facilities will be included.

- Measure N – Non-structural Four

REQUIRES FUTHER STUDY

Figure 6.16-3 shows the footprints for measures A through J. The alignment running from Hancock County to Jackson County is the footprint for measures A, through E, and the alignment going from Harrison County east to Jackson County is the footprint for measures F through J. The highlighted areas in figure 6.16-2 above represent the footprint of the nonstructural measures K through N.

6.16.6 National Economic Development (NED)

The purpose of this section is to document investigations conducted to identify the National Economic Development (NED) benefits of each of the potential measures previously listed. For this analysis, NED benefits are the reduced inundation damages of assets and their contents when one of the potential measures is in place. Typically, NED benefits are annualized over the period of the analysis (average annual benefits) and then compared to annualized costs over the period of analysis (average annual costs). This comparison is commonly known as the benefit-to-cost ratio (BCR). For purposes of this analysis, no benefit-to-cost ratios will be calculated as per the legislative Congressional language authorizing this study. The Coastal Mississippi Comprehensive Plan Report was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "…***that the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project plan features based upon maximizing net national economic development benefits…"*** More detail on the authorizing language can be found in the MsCIP Comprehensive Plan Main Report.

6.16.6.1 Future Without-Project Conditions

Equivalent annual surge damages for several future without-project scenarios were evaluated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Each of the measures were evaluated and compared to the without-project conditions in order to calculate equivalent annual damage reduction. Future without-project scenarios three, four, five, and six were applicable for the inland barrier area.

Future scenario one is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Structures will be rebuilt to what they were pre-Hurricane Katrina; residential back to residential, commercial back to commercial, etc. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Inland Barrier area.

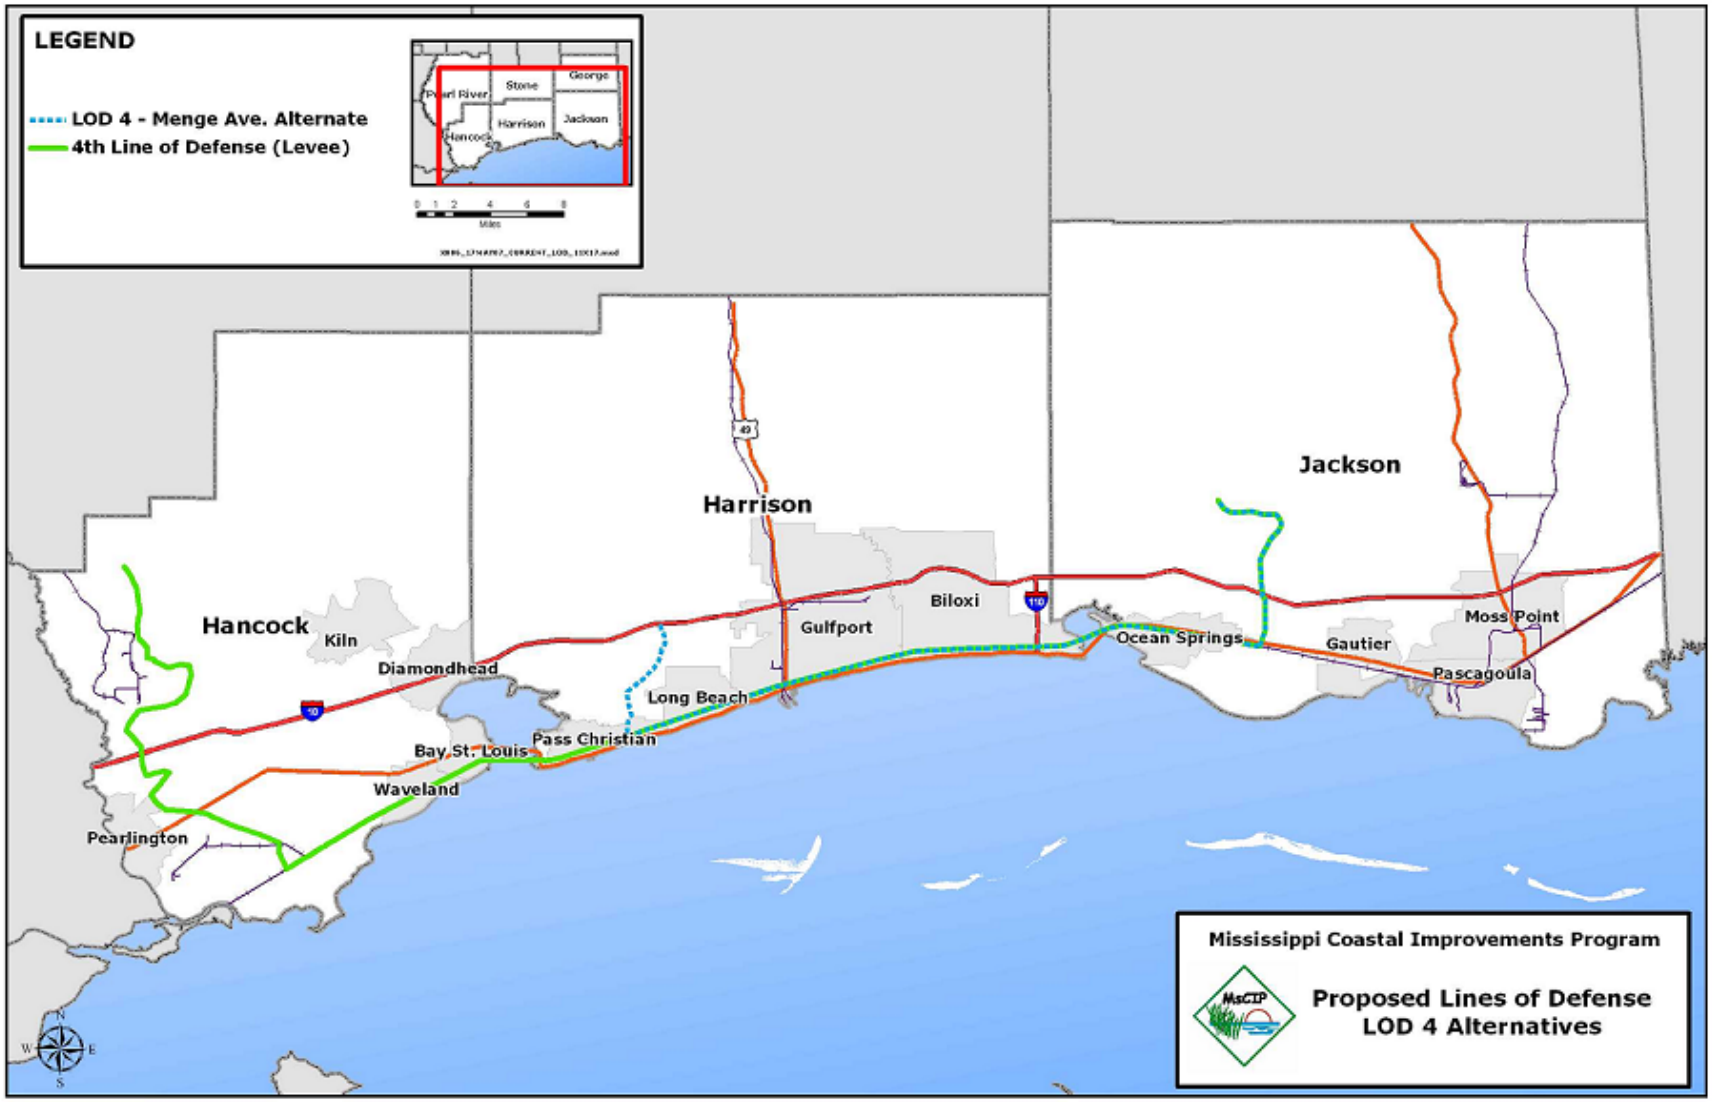

Figure 6.16-3. Footprints for the Inland Barrier Levees Alignments

Future scenario two is the full redevelopment of structures within the study area by the year 2012 with no relative sea level rise over the 100-year period of analysis. Structures will be rebuilt to what they were pre-Hurricane Katrina; residential back to residential, commercial back to commercial, etc, with the exception of the water front areas for planning units one and two. In these planning units, the scenario will address what if commercial and casino redevelopment would occur along the water front and Back Bay areas. This future scenario, as previously noted in section 5.3, is for sensitivity purposes only and will not be evaluated against all of the potential measures for the Inland Barrier area.

Future scenario three has the same redevelopment as future scenario one with a maximum relative sea level rise of 2.0-feet NAVD88. Equivalent annual damages that could occur under this scenario are $426,040,000 (rounded to the nearest thousand). These damages are the damages expected for this scenario that are attributed to all fifty-four planning units without a project in place.

Future scenario four has the same redevelopment as future scenario two with a maximum relative sea level rise of 2.0-feet NAVD88. Equivalent annual damages that could occur under this scenario are $434,040,000 (rounded to the nearest thousand). These damages are the damages expected for this scenario that are attributed to all fifty-four planning units without a project in place.

Future scenario five has the same redevelopment as future scenario one with a maximum relative sea level rise of 3.4-feet NAVD88 over the period of analysis. Equivalent annual damages that could occur under this scenario are $475,200,000 (rounded to the nearest thousand). These damages are the damages expected for this scenario that are attributed to all fifty-four planning units without a project in place.

Future scenario six has the same redevelopment as future scenario two with a maximum relative sea level rise of 3.4-feet NAVD88 over the period of analysis. Equivalent annual damages that could occur under this scenario are $483,700,000 (rounded to the nearest thousand). These damages are the damages expected for this scenario that are attributed to all fifty-four planning units without a project in place.

6.16.6.2 Equivalent annual damages Reduced

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios and the damages incurred with the measure in place. The HEC-FDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each measure. The inventories are the same as the without-project inventory except that footprints of inland barrier and surge barrier and the acquisitions were deleted from the inventory and flood proofed (structure to be raised in place) structures were given a specific first floor elevation. The structure inventories for each of the HEC-FDA with-measure runs are as follows:

- Measure A – Inland Barrier and Surge Barrier at Elevation 20.0-feet NAVD88

This measure includes the without-project inventory less 2,426 parcels that were deleted out of the inventory. Of those, 506 parcels were estimated to be impacted in planning unit one, 1,580 in planning unit two, and 340 in planning unit three. These parcels represent the footprint of the inland barrier and surge barrier across the three planning units and some portion of the total would have to be purchase for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted

from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure B – Inland Barrier and Surge Barrier at Elevation 30.0-feet NAVD88

This measure includes the without-project inventory less 2,746 parcels that were deleted out of the inventory. Of those, 576 parcels were estimated to be impacted in planning unit one, 1,784 in planning unit two, and 386 in planning unit three. These parcels represent the footprint of the inland barrier and surge barrier across the three planning units and some portion of the total would have to be purchase for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure C – Inland Barrier and Surge Barrier at Elevation 40.0-feet NAVD88

This measure includes the without-project inventory less 3,087 parcels that were deleted out of the inventory. Of those, 634 parcels were estimated to be impacted in planning unit one, 2,025 in planning unit two, and 428 in planning unit three. These parcels represent the footprint of the inland barrier and surge barrier across the three planning units and some portion of the total would have to be purchase for its construction. At this level of analysis, it is assumed that all of the structures identified to be touched in any way by the ring levee would be purchased; therefore all were deleted from the without-project structure inventory. Some of the parcels are wetland impacts and are discussed below in the Environmental Quality section.

- Measure D – Levee for Roadway - Elevation 20.0-feet NAVD88

REQUIRES FUTHER STUDY

- Measure J - Levee for Roadway with Menge Ave Alt - Elevation 30.0-feet NAVD88

REQUIRES FUTHER STUDY

- Measure K - Non-structural One

This measure includes the acquisition of 20,308 parcels with structures and vacant land, and the flood proofing (elevate in place) of 10,524 structures to a range of elevations from 11.0-feet to 22.35-feet NAVD88 depending on the planning sub-unit. The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is

detailed in the Non-structural Appendix. This elevation was determined to be approximately the ABFE level of protection is defined as still water elevation, plus wave run-up plus and estimate for waves (depth divided by two), and is the minimum elevation that a non-structural plan could provide.

- Measure L – Non-structural Two to Elevation 20.0-feet NAVD88

REQUIRES FUTHER STUDY

- Measure M – Non-structural Three to Elevation 30.0-feet NAVD88

RFS – Requires Further Study.

6.16.6.3 Residual Damage

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damage is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table". Residual damage by measure is shown in table 6.16-4.

Table 6.16-4.

6.16.7 Environmental Quality (EQ)

6.16.7.1 Impacts of Inland Barrier Area Measure

The Engineering Research and Development Center Wetlands and Coastal Ecology Branch were asked to conduct an assessment of potential impacts to wetlands as a result of constructing various levees and seawalls along the Mississippi Gulf Coastal Plain. This report summarizes the results of the assessment. The analysis of impacts included two components:

1. A calculation of total acreage of all wetlands (by type and planning reach) that is directly under the levee footprints.

2. A modified Hydrogeomorphic (HGM) wetland rapid assessment of impacted Estuarine/Tidal Fringe wetlands, based on the Mississippi and Alabama Gulf Coast HGM guidebook (Shafer et al., 2007), with impacts reported as loss of functional units. Tables 6.16-5, and 6.16-6, and 6.16-7 show the impacts of the inland barrier and surge barrier at elevations 20.0, 30.0, and 40.0-feet NAVD88 respectively.

Nonstructural measures would have no construction activities other than demolition and disposal of building materials in an approved land fill occurs as a result of this measure. More detail on the impacts of the structural and nonstructural measures for the Inland Barrier area can be found in the Environmental Appendix.

6.16.9 Regional Economic Development (RED)

The purpose of this analysis is to show the economic impact of the proposed project measures on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local areas of Jackson County, Harrison County and Hancock County, Mississippi. The expenditures for the measures are estimated to be $3,559,900,000 for the Inland Barrier A measure, $5,039,300,000 for the Inland Barrier B measure, $6,176,800,000 for the Inland Barrier C measure, $3,329,500,000 for the Inland Barrier D measure, $5,076,000,000 for the Inland Barrier E measure, $1,257,100,000 for the Inland Barrier F measure, $1,809,000,000 for the Inland Barrier G measure, $2,583,000,000 for the Inland Barrier H measure, $1,295,300,000 for the Inland Barrier I measure, $1,954,800,000 for the Inland Barrier J measure. Moreover, the total Operation and Maintenance (O&M) expenditures, which are based on the total present worth O&M costs over the period of analysis, are estimated to be $867,581,000 for the Inland Barrier A measure, $1,256,365,000 for the Inland Barrier B measure, $1,5556,235,000 for the Inland Barrier C measure, $864,754,000 for the Inland Barrier D measure, $1,257,707,000 for the Inland Barrier E measure, $333,305,000 for the Inland Barrier F measure, $482,518,000 for the Inland Barrier G measure, $696,444,000 for the Inland Barrier H measure, $338,857,000 for the Inland Barrier I measure, $522,460,000 for the Inland Barrier J measure. The following tables, 6.16-9 through 6.16-16, summarize the EIFS model inputs and outputs for the various measures.

6.17 Evaluation of Coast Wide Nonstructural Flood Damage Reduction Measures

6.17.1 General

This section describes the evaluation of nonstructural measures for the entire fifty-four planning sub-units that compose the MsCIP study area. Formulation of potential measures evaluated in this section was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC). There are a number of measures that can be classified as “nonstructural”. In some cases such as dry flood proofing by the use of ring walls, a nonstructural measure can approximate a structural solution when expanded to protect a large contiguous complex (college campus, industry, or commercial area). When judiciously applied, nonstructural measures can result in reductions in inundation damages and losses of life to structure occupants.

6.17.2 Opportunities

The following opportunities were identified for the area:

- Hurricane storm damage reduction or remediation.
- Preservation of Fish and Wildlife.

Table 6.16-9.

6.17.3 Assumptions

The following assumptions were used in this analysis.

- The FY 2008 discount rate of 4-7/8 percent was used in estimating average annual benefits and costs.
- Price levels are FY-08, unless otherwise stated.
- A 100-year period of analysis (2012 to 2111) was used to calculate average annual benefits and costs.

6.17.4 Types of Nonstructural Measures

The nonstructural measures described below can be grouped into several general categories including:

- Flood Preparedness
- Floodplain Management, Floodplain Zoning and Flood Insurance
- Building codes
- Land Use Regulation and Zoning
- Development Impact Fees, TDR, TPR, and Redirection
- Land Taxation policies and development
- Flood proofing (elevation of structure in place, wet/dry proof, etc.)
- Permanent evacuations (acquisitions)
- Relocations of public buildings

Corps of Engineers documents and regulations as well as the technical papers and bulletins of other Federal and state agencies that address flooding from storms and hurricanes contain lists of possible nonstructural measures. Generally speaking, each of these identified measures can be applied either singly or in combination with other nonstructural or structural measures to attain project goals and planning objectives. In an effort to simplify the formulation of nonstructural plans, the NSFPC went through an initial screening process to determine which plans were feasible for detailed evaluation. The screening process used by the NSFPC for each of these types of measures can be found in the Nonstructural Appendix.

6.17.5 Historic Conditions

The Mississippi Gulf Coast is no stranger to large storm surge events. On August 17, 1969, Hurricane Camille impacted the area in a similar fashion to Hurricane Katrina. Hurricane Camille made landfall at Bay St. Louis, Mississippi only a few miles way from Hurricane Katrina's landfall path. The total surge area ranged from lower Plaquemines Parish in Louisiana to Perdido Pass, Alabama. Maximum surge from Hurricane Camille on the Mississippi coast ranged from 21.7-feet above m.s.l. in planning unit one, to 24.2-feet above m.s.l. in planning unit two, and 15.8-feet above m.s.l. in planning unit 3.

Damage to the Mississippi Coast from Hurricane Camille was extensive. Federal relief expenditures topped 100 million dollars at 1970 prices, over 600 million dollars at today's prices after accounting

for inflation. The magnitude of this number is astounding considering that many of the relief programs that exist today did not exist for Hurricane Camille. Chapter IV of this appendix describes in detail damage statics caused by Hurricane Camille surge inundation.

6.17.6 Existing Conditions

On August 29, 2005, Hurricane Katrina made land fall in Hancock County, Mississippi just east of the Pearl River. By virtually all accounts, it was the single largest disaster in U.S. history. Storm surge from Hurricane Katrina was the largest that has ever hit the continental United States. The surge inundated approximately 484 square miles of southern Mississippi. The relief expenditures in Mississippi alone have totaled in the billions of dollars. Figure 6.17-1 shows the inundation footprint of Hurricane Katrina.

Figure 6.17-1. Hurricane Katrina Path and Extent of Hurricane Katrina Surge in Planning Units One, Two, and Three

The three planning units suffered tremendous devastation from Hurricane Katrina's surge. The PDT estimates that 32,446 structures were significantly destroyed (at least fifty-percent or more), with another 15,000 to 25,000 suffering moderate to minimal inundation damage. Of the structures sustaining significant destruction, 9,555 were in planning unit one, 16,528, in planning unit two, and 6,363 in planning unit three. Of those significant loss structures, approximately 19,000 claims were paid out by the Federal Emergency Management Agency's (FEMA's) National Flood Insurance Program (NFIP) totally over $2.3 Billion dollars, with the average claim around $137,000. Currently, no accurate data exists for uninsured losses, but estimates range in the billions of dollars. Table 6.17-1 displays the significantly damaged structures by planning unit and by structure category. Chapter IV of this appendix describes in greater detail the coast wide damage caused by Hurricane Katrina surge inundation.

Table 6.17-1.
Structures Damaged 50% or More by Planning Unit and by Category

	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Commercial	1,267	1,794	378	**3,439**
Residential	8,099	14,500	5,780	**28,379**
Municipal	127	89	136	**352**
Mobile Home	62	145	69	**276**
Total	**9,555**	**16,528**	**6,363**	**32,446**

Source: Field inventory conducted by the Corps PDT.

6.17.7 Without-Project Conditions

This section summarizes the coast wide future without-project conditions used as the basis for the evaluation of nonstructural measures. Future without-project conditions are defined as the characteristics of the area over the period of analysis should no federal project be implemented. The coast wide future without-project conditions are described in greater detail in Chapter IV of this appendix.

Given the vast devastation caused by hurricane Katrina, the projection of the future without-project conditions contains significant uncertainty. In an attempt to reduce this uncertainty, scenario testing was implemented. Scenario testing is where multiple future scenarios are created in order to evaluate what would happen if observed variables or assumptions do not happen as projected, and attempts to answer the 'what if' questions that arise when making forecasting assumptions and predictions. Table 6.17-2 summarizes the six future-without project scenarios created for the MsCIP Comprehensive Plan. As described in chapter IV, Future without-project scenarios one and two are for testing the sensitivity of effects of the increment between a no relative sea level rise scenario and the expected relative sea level rise scenario. Therefore, only future without-project scenarios three, four, five, and six were used to evaluate the nonstructural measures.

Table 6.17-2.
Overview of Future Scenarios

Future Scenario	Redevelopment Type	Relative Sea Level Rise	Description
Future Scenario 1	Residential	None	Rebuild structures as existed pre-Hurricane Katrina with no relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 2	Mixed Residential & Commercial	None	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, no relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 3	Residential	Expected (up to 2.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina with up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 4	Mixed Residential & Commercial	Expected (up to 2.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, a up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 5	Residential	High Rate (up to 3.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina with up to 3.4-feet of relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 6	Mixed Residential & Commercial	High Rate (Up to 3.4-feet depending on location)	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, up to 3.4-feet of relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.

Future Scenarios One and Two are included only to evaluate the effects of relative sea level rise. These Future scenarios will not be used in the evaluation of potential measures. Futures Three, Four, Five, and Six will be the future scenarios by which potential measures will be evaluated depending on the planning unit.

Tables 6.17-3, 6.17-4, and 6.17-5 summarize the structure inventory for future without-project scenarios three and five.

Table 6.17-3.
Futures Without-Project Scenarios Three and Five Inventory Parcels by Planning Unit and by Structure Category

Structure Categories	Planning Unit One	Planning Unit Two	Planning Unit Three	Total
Residential	17,907	49,121	49,688	**116,716**

Equivalent annual damages for future without-project scenarios three, four, five, and six were estimated using the HEC-FDA program and based on the structure inventories described in the previous tables. Table 6.17-9 summarizes the equivalent annual damages for those scenarios. More detail can be found in chapter IV.

Table 6.17-9.
Equivalent Annual Without-Project Damages by Planning Unit and Future Scenario

Without-Project Damages	Future 3 Damages	Future 4 Damages	Future 5 Damages	Future 6 Damages
Planning Unit One	$218,050,000	$222,220,000	$237,310,000	$241,520,000
Planning Unit Two	$103,280,000	$107,120,000	$115,470,000	$119,760,000
Planning Unit Three	$104,700,000	$104,700,000	$122,420,000	$122,420,000
Total	**$426,040,000**	**$434,040,000**	**$475,200,000**	**$483,700,000**

1/ Damages are rounded to the nearest thousand.
2/ Futures Two, Four, and Six do not apply to planning unit three, therefore total damages are the same as future scenarios one, three, and five.

6.17.8 Equivalent Annual Damages Reduced and Residual Damages

Equivalent annual damages reduced are calculated as the difference between the damages under the future without-project scenarios three and five and the damages incurred with the measure in place. The HEC-FDA model was run for each measure to determine the damages reduced as compared to the without-project scenario.

In order to provide the HEC-FDA model with accurate information about the economic characteristics of each measure, separate inventories were created for each of the nonstructural measures. The inventories are the same as the without project inventory except that footprints of the acquisitions were deleted from the inventory and floodproofed structures (structures to be elevated in place) were given a higher elevation. The structure inventories for each of the HEC-FDA measure runs are as follows:

- NS-Measure A Acquisition and Floodproofing to Advisory Base Flood Elevation (ABFE) Level

This measure includes the acquisition of 33,198 structures and vacant parcels and the flood proofing (raise structure in place) of 25,419 structures to the ABFE elevation that is applicable for the planning sub-unit. This elevation was determined to be approximately the ABFE level of protection and is defined as still water elevation, plus wave run-up, plus an estimate for waves (depth divided by two), and is the minimum implementation elevation that a nonstructural measure do to the requirements of the National Flood Insurance Program (NFIP).The formulation process for this measure was conducted by the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and is detailed in the nonstructural appendix. Figure 6.17-2 shows the areas included in this plan. Figures 6.17-3, 6.17-4, and 6.17-5 show the same areas by planning unit.

- NS Measure B: Acquisition and Floodproofing to elevation 20.0-feet NAVD88

Requires Further Study

- NS Measure C: Acquisition and Floodproofing to elevation 30.0-feet NAVD88

Requires Further Study

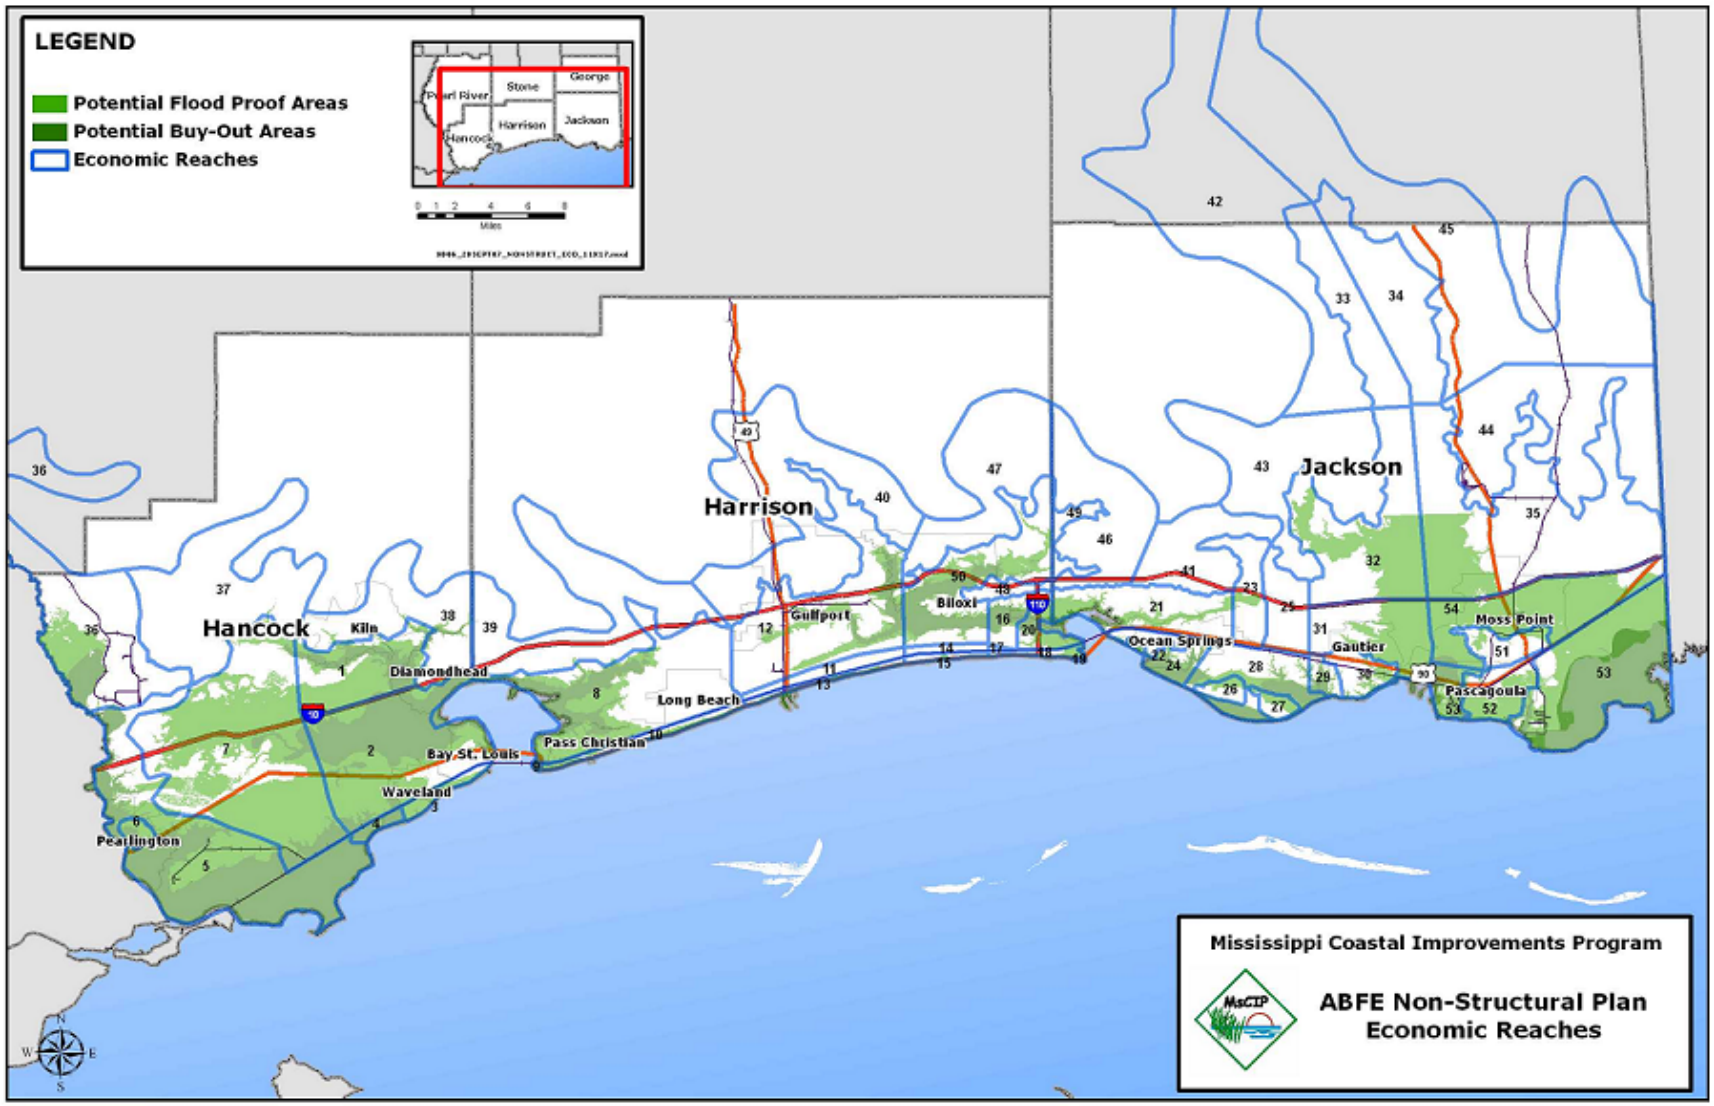

Figure 6.17-2. Nonstructural ABFE measure footprint

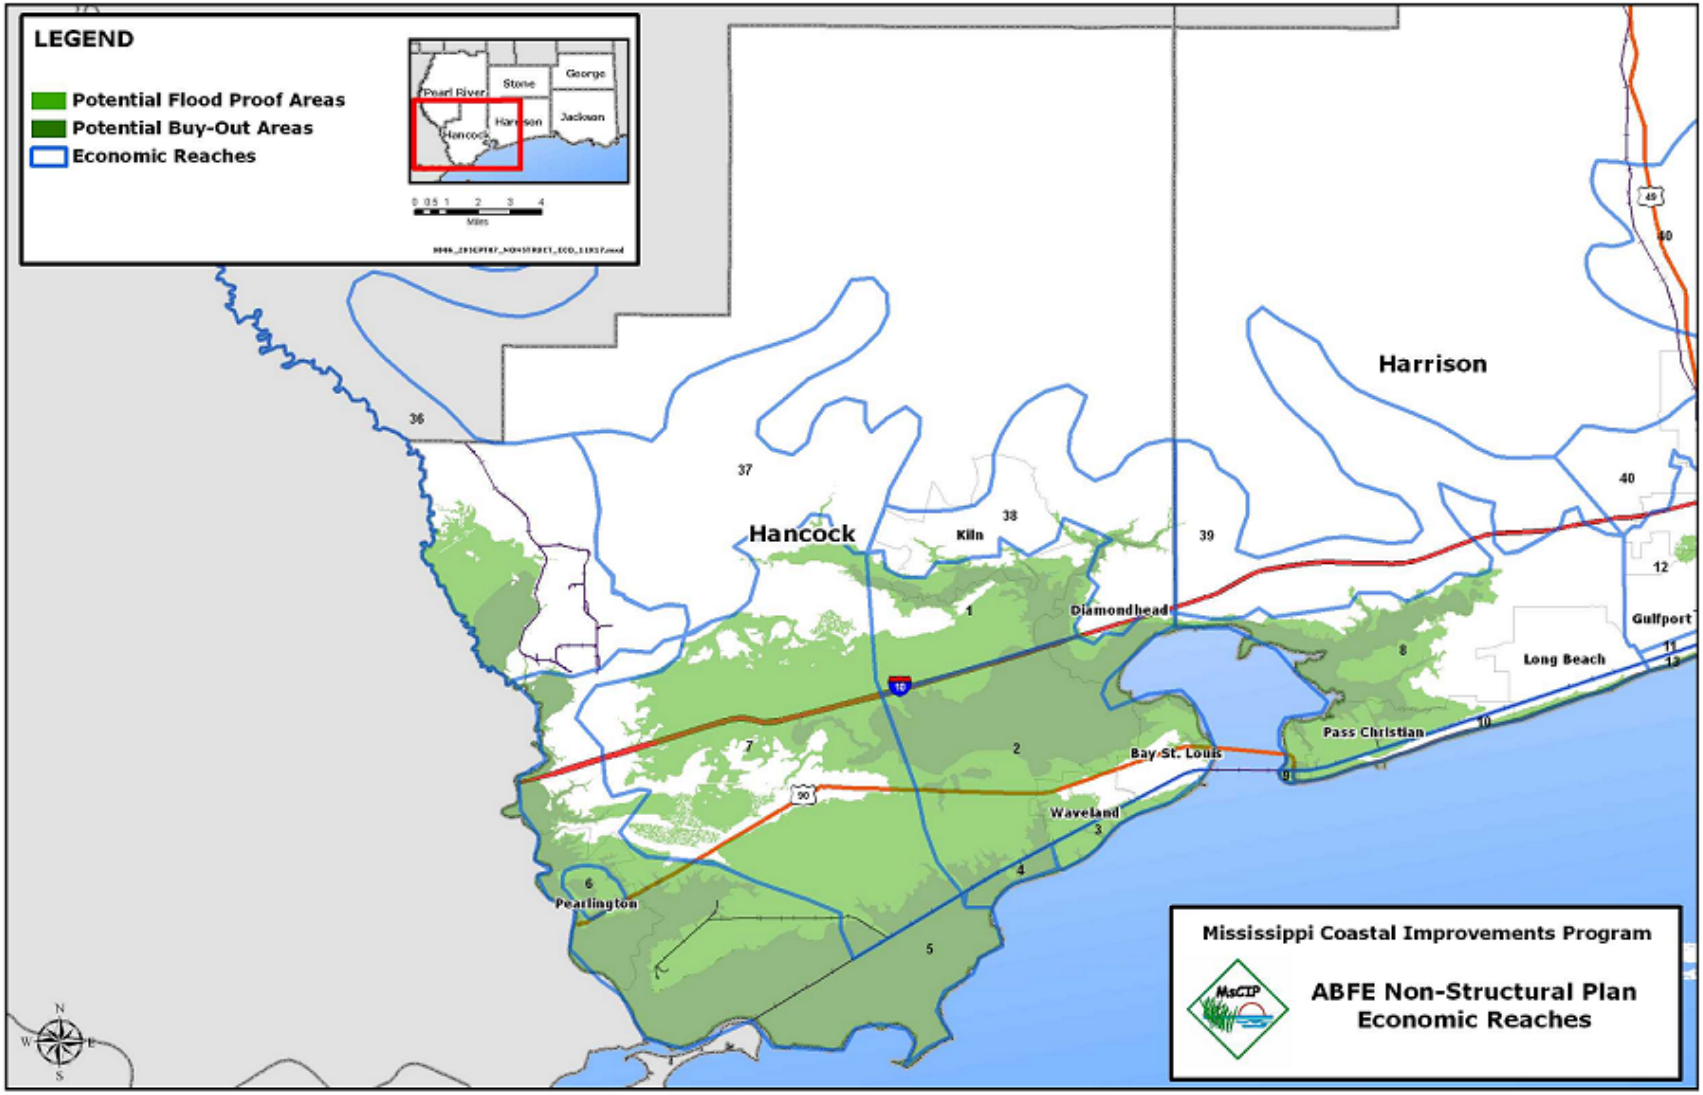

Figure 6.17-3. Nonstructural ABFE measure for planning unit one – Hancock County

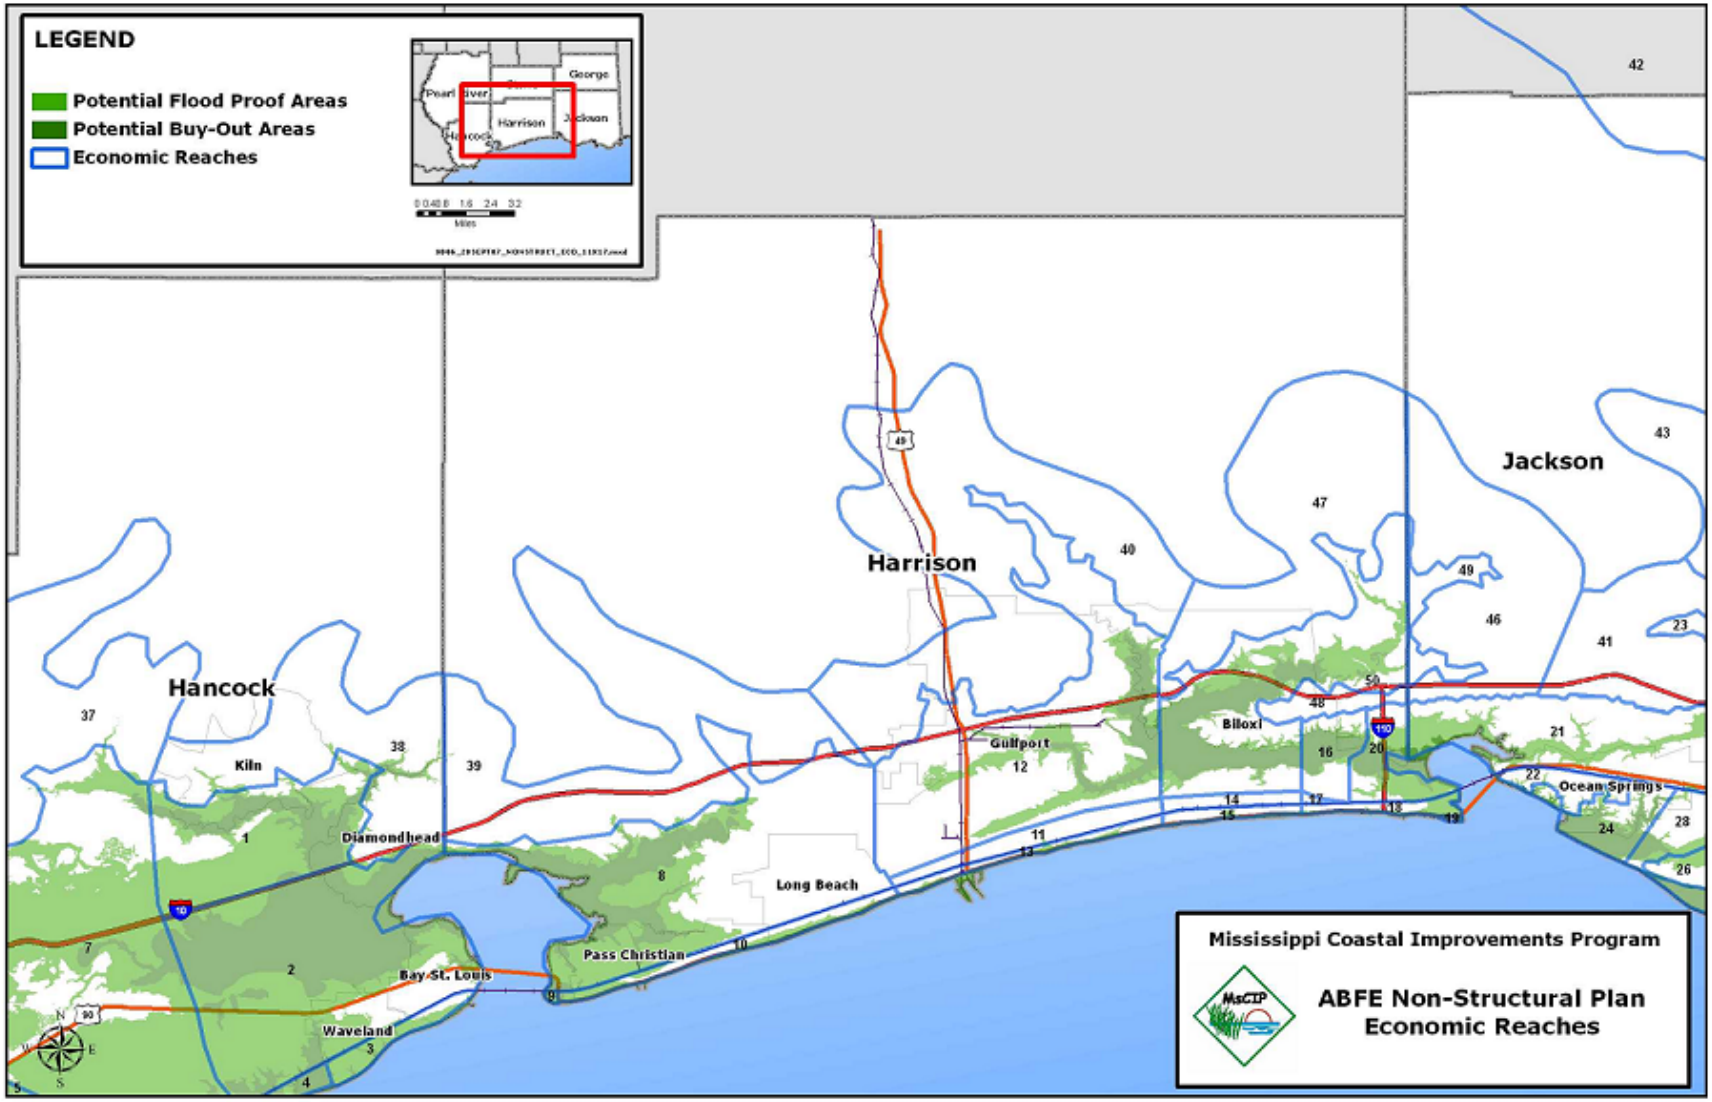

Figure 6.17-4. Nonstructural ABFE measure for Planning Unit Two – Harrison County

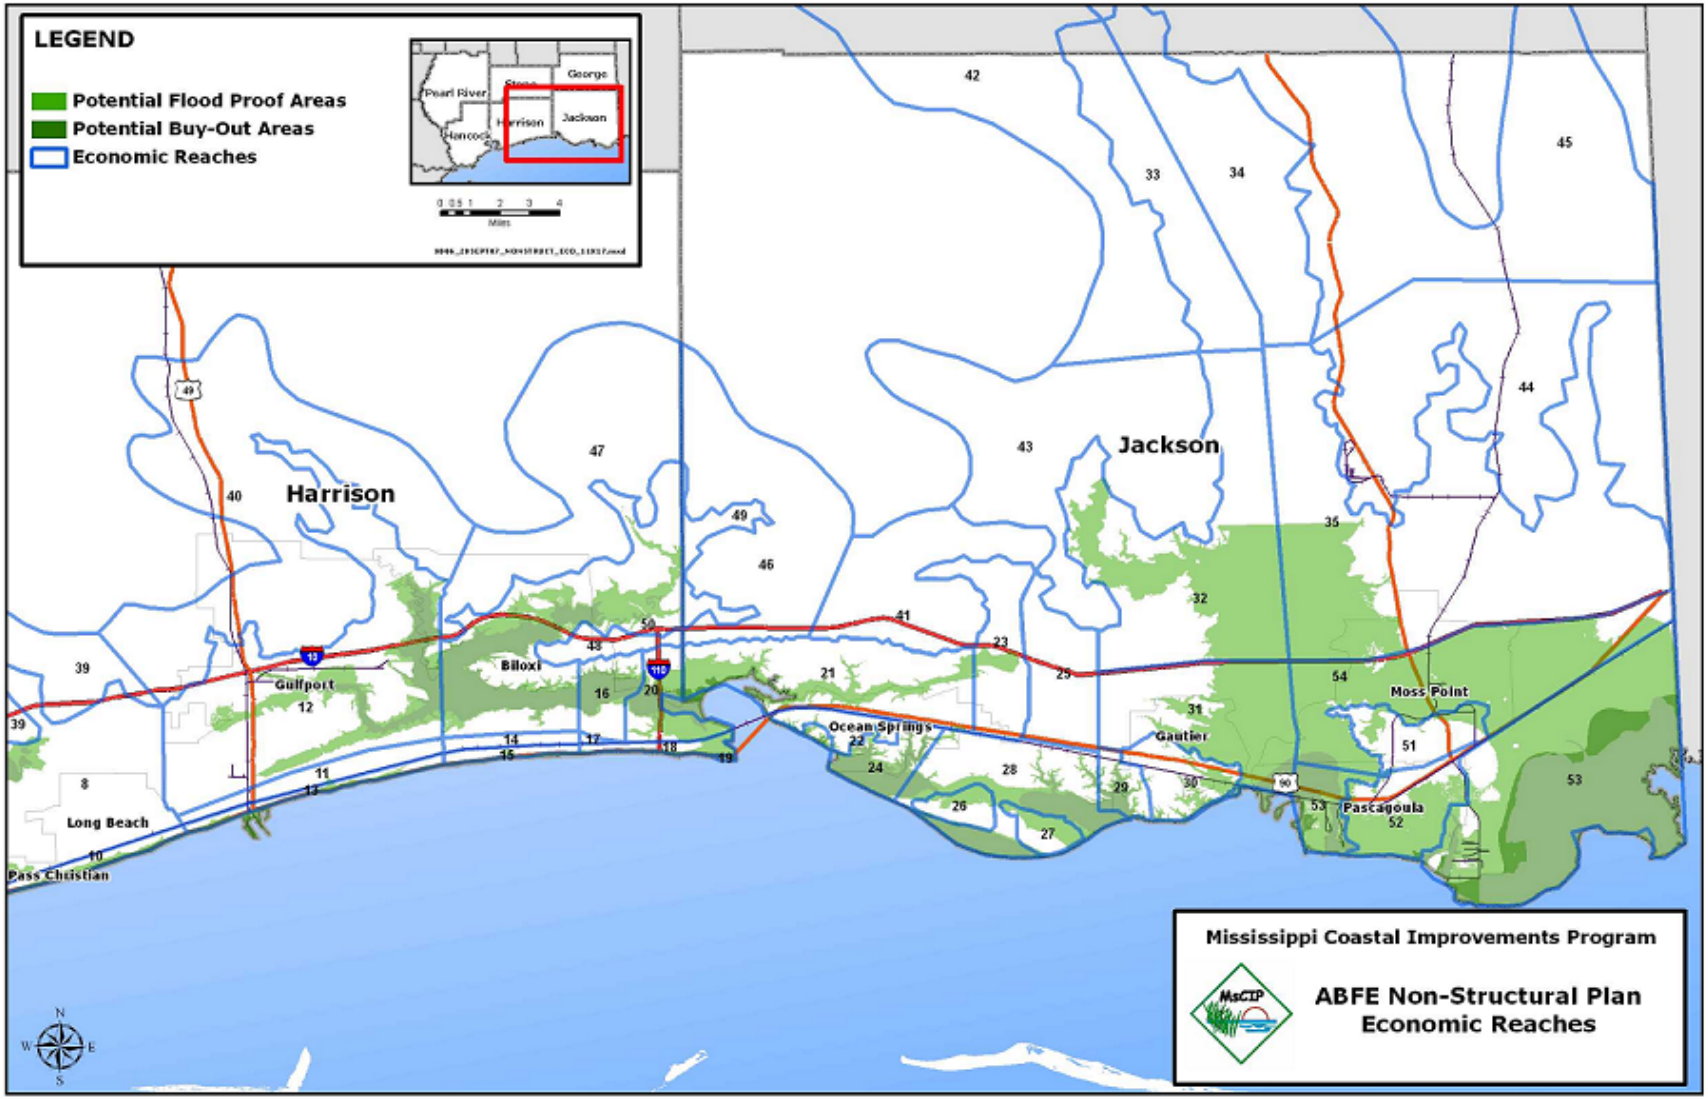

Figure 6.17-5. Nonstructural ABFE Measure for Planning Unit Three – Jackson County

- NS Measure D: Acquisition and Floodproofing to elevation 40.0-feet NAVD88

Requires Further Study

Residual damage is the equivalent annual damages that still remain even when a project is in place. Residual damage is calculated as the future without-project equivalent annual damages minus the damages reduced of the various measures. The purpose of residual damage is to calculate and communicate the portions of damages that will not be reduced by the implementation of a plan or "what damages are left on the table."

6.17.9. Summary of Damages

Table 6.17-10 summarizes the without-project damages, damages reduced, and residual damages by measure for scenarios three and five.

Table 6.17-10.
Summary of Damages by Potential Measure for Future Scenarios Three and Five

Damages are rounded to the nearest thousand dollars.
RFS – Requires Further Study

6.17.10 Summary of Costs

Table 6.17-12 summarizes the costs by measure.

Table 6.17-12.
Summary of Costs by Nonstructural Measure

Measures	Total Cost to Implement (First Cost) ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	IDC[1] ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0
Measure A ABFE Nonstructural	$16,782,494	$825,216,000	$400,000	N/A	$825,616,000
Measure B 20FT Nonstructural	RFS[2]	RFS	RFS	N/A	RFS
Measure C 30FT Nonstructural	RFS	RFS	RFS	N/A	RFS
Measure D 40FT Nonstructural	RFS	RFS	RFS	N/A	RFS

1/ Due to the massive scale and extended time frame of implementation of the coast wide nonstructural plans, IDC is not able to be calculated at this time. 2/ RFS – Requires Further Study.

6.17.11 Alternative Land Use

Each of the nonstructural measures contains some portion of the plan that consists of the acquisition of structures and parcels. Should any of the plans be implemented, the land contained in the footprint could never be used again for habitable use. However, there are alternative uses of land for these areas such as recreational areas, ecotourism areas, or environmental restoration. Each of these alternative uses of the acquisition area land would have associated benefits and costs. Further study would be required to determine the most cost effective use of the acquisition lands.

6.17.12 Other Social and Economic Benefits

In addition to the direct structure damage reduction benefits and the alternative use of land, acquisition of structures would have other social and economic benefits. These benefits include the reduction of risk to health and human safety, reduction of evacuation and subsistence costs (travel and stay to evacuate, non-profit assistance such as food, etc.), reduction of emergency costs following storm events (debris removal, temporary housing, etc.), reduction of residential reoccupation costs, reduction of commercial clean-up costs, and future infrastructure savings to the tax base for roads and utilities. For example, the bullets below are from the Louisiana Coastal Master Plan[4] estimates for damages in these categories. These numbers are based on Louisiana data and do not apply for Coastal Mississippi, but provide a sense of the potential costs savings that could be reduced.

- Combined federal, state, parish and municipality spending average of $1,450 for inundated residential structures and $3,850 for inundated non-residential structures,
- Evacuation and subsistence costs of up to $21,284 per household at risk,
- Reoccupation costs of up to $7,133 per inundated residential structure,
- Commercial clean-up and restoration costs of up to $16, 245 per inundated commercial structure.

Although these benefits can be shown on a per structure basis, significant economies of scale can be achieved with the acquisition of clusters of structures including streets, neighborhoods, and communities. Due to timing constraints of the study, quantifiable dollar amounts for these benefit categories could not be identified, but would be estimated as part of implementation or further study. Careful coordination between the Corps and local stakeholders would be required prior to implementation in order to optimize the economic efficiencies that could be gained from acquisition of parcels.

6.17.13 Summary of Regional Economic Development Benefits

The purpose of this section is to show the economic impact of the proposed measure on business (sale volumes), income, employment, and population of the local area. Each of the measures would affect the local area of the three coastal counties of Mississippi. The first cost expenditures for the ABFE nonstructural measure are estimated to be $15,394,143,000, with an additional $8,134,000 for the total present worth of the operation and maintenance (O&M) expenditures assuming a 100-year period of analysis and an FY 08 discount rate of 4.875-percent. The 20FT elevation, 30FT elevation, and 40FT elevation coast wide nonstructural plans require further study to determine regional impacts. The following tables, 6.17-13 through 6.17-16, summarize the EIFS model inputs and outputs for the coast wide nonstructural plan.

[4] Louisiana Coastal Master Plan Appendix F: Economic Analysis.

Table 6.17-13.
EIFS Model Construction Costs Inputs for the Nonstructural Measures

6.18 Forrest Heights Levee, City of Gulfport, Harrison County

6.18.1 General

The culturally historical Forest Heights residential community in the City of Gulfport, Harrison County, Mississippi, has frequently been inundated by flood waters due to storm surges from the Mississippi Sound and from inland flooding along the lower Turkey Creek. Water reached a depth of 2-8 ft over the entire community during Hurricane Katrina inundation. The Forest Heights levee is proposed to be constructed as a pilot project for the MsCIP comprehensive plan. The levee will address the combination of storm surge protection, inland flooding protection, and evacuation. The levee is intended to be constructed to a height such that the levee might be certified under the National Flood Insurance Program. A preliminary engineering analysis suggests a levee built to approximately elevation 21 feet NAVD ’88 would satisfy or exceed certification elevation criteria.

Engineering performance and economic evaluations of protection options were done using the Hydrologic Engineering Center’s (HEC) Flood Damage Analysis (FDA) computer application HEC-FDA. HEC-FDA modeling was done using variations in with-project conditions compared to the future without-project conditions for the Turkey Creek study. Details regarding the methodology are presented in the Economic Appendix. Additional evaluation to determine the precise levee height will be performed during final engineering and design based upon analyzing the risk and uncertainty associated with the coincident occurrence of inland flooding and storm surge impacts.

6.18.2 Location

The Forrest Heights community is located in an area known as North Gulfport within the City of Gulfport on the Mississippi Gulf Coast. The location of the levee at Forrest Heights is shown below in Figures 6.18-1. The community lies along the lower Turkey Creek floodplain, which has a tendency to frequently exceed its stream channel capacity and flood adjacent low-lying areas.

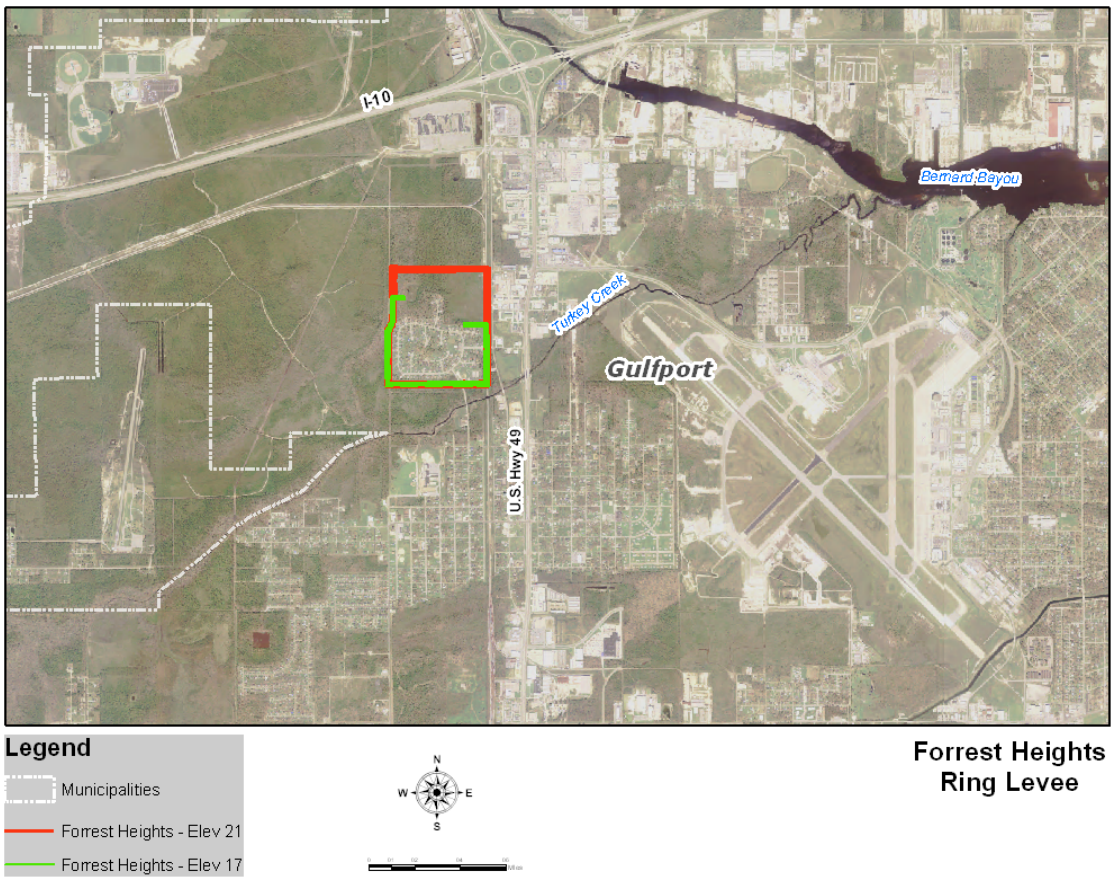

Figure 6.18-1. Forrest Heights Ring Levee Location

6.18.3 Assumptions

- The New Orleans District Corps of Engineers fresh water depth-damage relationships for residential and non-residential property were considered appropriate and accurate for the properties in this area,
- 50-year period of analysis,
- FY 2008 Federal discount rate of 4.875-percent,
- All values are equivalent to October 2007 dollars.

6.18.4 Existing Conditions

The community of Forrest Heights lies on the bank of Turkey Creek about 2.6 miles from the mouth at Bernard Bayou. Ground elevations over most of the residential area are between elevations 10-14 ft NAVD88. Drainage is mostly along streets and through natural drainage ways to the Turkey Creek. Impacts from flooding and hurricanes have been devastating. Hurricane Katrina in August, 2005 resulted in significant flood damages to residences in the Forrest Heights community. A levee with top width of 6 ft was constructed around the community to elevation 16.5 ft NGVD with side slopes of 1 vertical to 1.5 horizontal in 1969, prior to Hurricane Camille. It has not had adequate maintenance and is a state of disrepair. It is scheduled to be restored to as-built condition by January of 2009. However, the restored levee will not be sufficient to meet the present day standard for certification

according to the existing FEMA flood profiles in the vicinity. It is assumed that the as-built condition of this restored levee will be the existing condition for this report.

6.18.5 Without-Project Conditions

The without-project condition is the most likely case to occur during the 50-year period when a project could be in place. Because the Forrest Heights area has been developed since the 1800's, all of the usable land within the community is presently developed and rebuilt since Hurricane Katrina. Damages considered in the analysis were inundation damages and emergency cost damages that would occur from future storm events. Inundation damages and damages reduced were estimated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) computer software program. Three future without-project scenarios were identified for the Forrest Heights area: existing relative sea level rise, moderate relative sea level rise and high relative sea level rise.

6.18.5.1 Coastal Hydraulic Data

This section describes the development of the existing relative sea level rise scenario. High water marks taken by FEMA after Hurricane Katrina in 2005 as well as the 4-ft(blue), 8-ft(dark green), 12-ft(green), 16-ft(brown), 20-ft(orange), and 20-ft(pink) ground contour lines and Hurricane Katrina inundation limits are shown below in Figure 6.18-2. The data indicates the water was as high as 18-20 ft NAVD88 near the site, totally inundating the entire area.

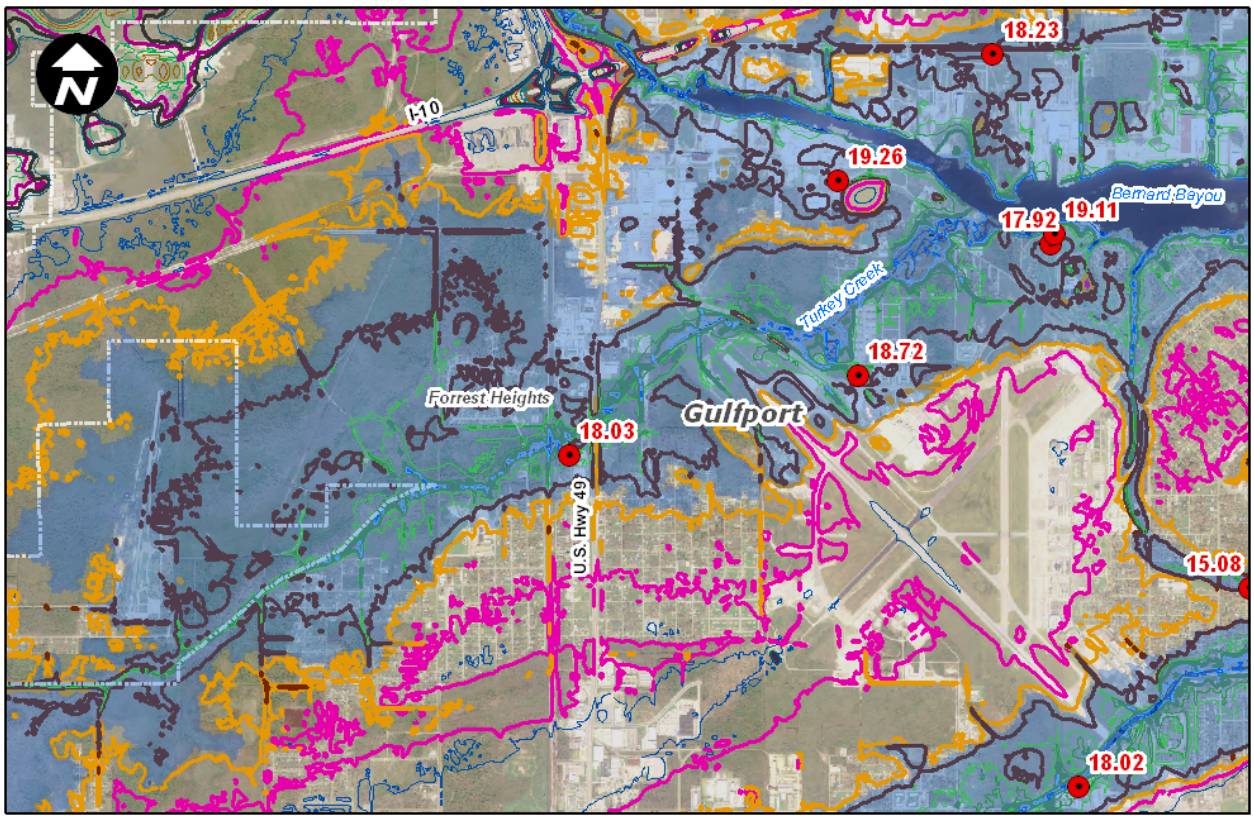

Figure 6.18-2. Hurricane Katrina Inundation and High Water, Forrest Heights

Stage-Frequency data for a suite of severe storms using Joint Probability Method (JPM) and hydrodynamic modeling were developed by the Engineer Research and Development Center (ERDC) for 80 locations along the study area. These data were combined with historical coastal tide gage frequencies for smaller storms to establish stage-frequency curves at 54 economic reaches in the study area. An expanded description of the procedure is presented in Section 2.13 of the Engineering Appendix. Points near Forrest Heights, at which data from hydrodynamic modeling was saved, are displayed in Table 6.18-1.

Table 6.18-1.
Surge Stage-Probability and Uncertainty

Annual Probability	Stage (Ft. NAVD88)	Standard Deviation (Feet)
0.04	8.8	0.6
0.02	11.6	1
0.01	13.7	1.5
0.002	17.2	2.5
0.001	18.3	2.9

It should be noted that the frequency curve reflects only that flooding resulting from storm surge in the gulf. The Forrest Heights community is also subject to riverine flooding by Turkey Creek. The preliminary FEMA Harrison County Flood Insurance Study (FIS) dated November 2007 provides computed Turkey Creek flood profiles which appear to have been adjusted for the effects of coincident surge in Back Bay of Biloxi. Table 6.18-2 shows relevant discharge and stage information from the FIS for Turkey Creek at Ohio Avenue, the southern entrance to the Forrest Heights community. In comparison to the preliminary FEMA Flood Insurance Study dated November 2007, which is based on contemporary (post-Katrina) FEMA contractor hydrodynamic modeling, the ERDC frequency curve, which is based on surge alone, suggests a lower stage associated with the annual one in one hundred chance (0.01 exceedance probability) event.

Table 6.18-2.
Turkey Creek Flood Stages At Ohio Avenue, Harrison County FIS.

Exceedance Probability	Discharge (cfs)	Stage (ft. NAVD '88)
0.1	2600	12
0.02	3650	14.2
0.01	5500	15.5
0.002	7950	18.3

Hydraulic data was developed for use in the Hydrologic Engineering Center's Flood Damage Analysis (HEC-FDA) program. The HEC-FDA program uses risk-based analysis methods for evaluating flood damage and flood damage reduction alternatives. The program relies on hydrologic, hydraulic, and economic data input. Uncertainties in these data are input and used by the model for computing annual damages. Version 1.2.3b dated August 2007 was used. As described in chapter 2 of this appendix, this is a customized version of the current official release version 1.2 dated March 2000. This section describes the model's hydrologic and hydraulic input as applied to the Forrest Heights community.

Forrest Heights is subject to both riverine and surge flooding. For this reason, a discharge-frequency curve and a stage-discharge relationship (also known as a 'rating curve') were developed for input

into the HEC-FDA model. The discharge-frequency curve was computed in FDA using synthetic statistics using the 0.5-, 0.1-, and 0.01 annual exceedance probability discharges from the preliminary Harrison County FIS (see Table 3.3.6-2). The version of FDA used extends the stage frequency curve to the 0.999 and 0.0001 annual exceedance values. Uncertainty about the discharge-frequency curve was computed by the FDA program assuming an equivalent period of record. Sensitivity analysis of discharge uncertainty with respect to the equivalent period of record was conducted. Interpretation of the standard error and apparent period of record of the underlying hydrologic information used to develop the FIS discharge values versus discharge uncertainty computed by the FDA program suggested that an equivalent period of record of 20 years provided a reasonable preliminary estimate of uncertainty of discharge in the un-gaged stream. The resultant discharge-frequency curve and curves at the 5% and 95% confidence limits are shown below in Figure 6.18-3 and the values are shown in Table 6.18-3. These relationships are representative in the vicinity of Ohio Avenue.

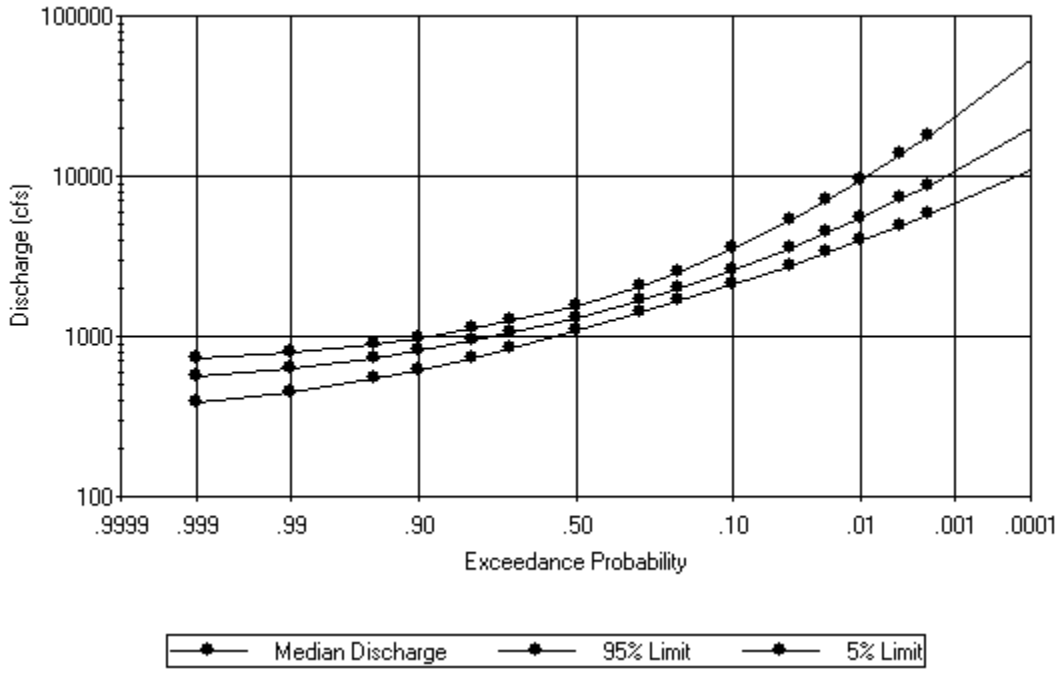

Figure 6.18-3. Computed Discharge-Frequency Curve, Turkey Creek at Ohio Avenue

Table 6.18-3.
Discharge-Frequency, Turkey Creek at Ohio Avenue

Exceedance Probability	Discharge (cfs)	Confidence Limit Curves Discharge (cfs) 95%	75%	25%	5%
0.9990	563	383	458	660	720
0.9900	634	447	525	733	795
0.9500	735	542	622	839	904
0.9000	811	614	696	918	986
0.8000	932	731	814	1,044	1,118
0.7000	1,045	840	924	1,165	1,245
0.5000	1,300	1,081	1,167	1,443	1,548
0.3000	1,678	1,412	1,511	1,882	2,051
0.2000	1,995	1,669	1,785	2,274	2,522
0.1000	2,601	2,118	2,281	3,066	3,515
0.0400	3,563	2,770	3,027	4,411	5,296
0.0200	4,449	3,330	3,684	5,716	7,104
0.0100	5,500	3,961	4,439	7,334	9,428
0.0040	7,211	4,935	5,625	10,093	13,561
0.0020	8,771	5,778	6,671	12,723	17,655
0.0001	19,704	11,042	13,464	33,224	52,792

The stage-discharge curve was developed by fitting an equation of the form $H = CQ^a$ (H = water surface elevation; Q is discharge; C and a determined by regression) through the Turkey Creek stage at cross section F as shown on the Turkey Creek Flood Profile, Plate 83P, of the preliminary FIS. The profile plate shows this location to have been adjusted for coincident probability of surge. The equation thus developed was used to extend the rating curve through a broader range of discharges than represented on the flood profiles. Uncertainty about the rating curve was assumed to be 1.5 feet at the 10-year and higher discharges based on FIS hydraulic modeling techniques and assuming a poor historic hydrologic data record (Turkey Creek is ungaged). The rating curve is shown in Figure 6.18-4.

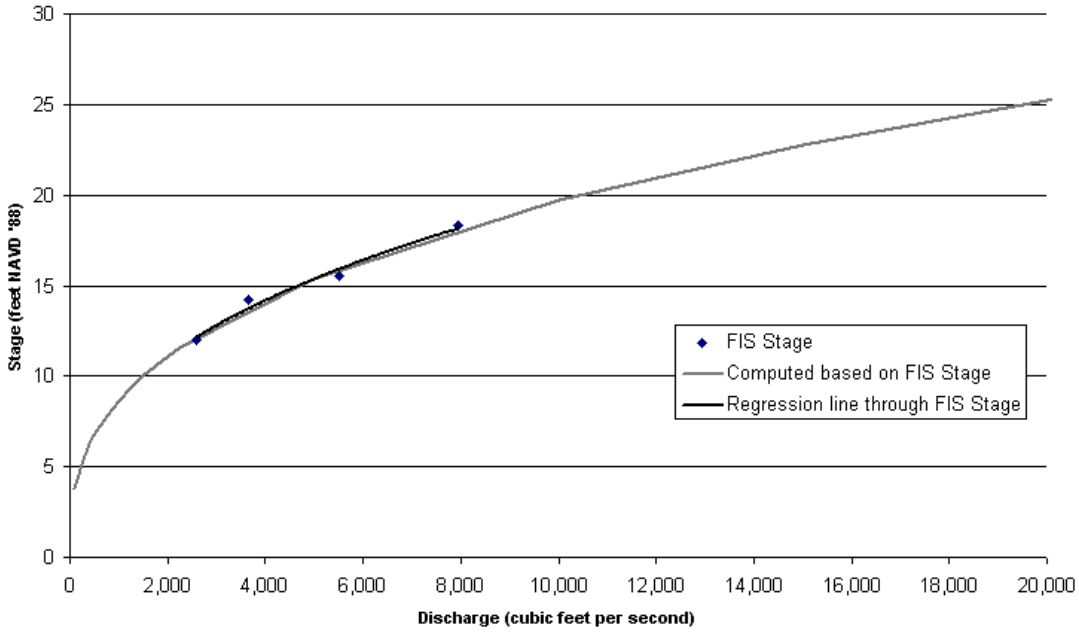

Figure 6.18-4. Computed Rating Curve, Turkey Creek at Ohio Avenue.

6.18.5.2 Summary of Without-Project Damages

Equivalent annual without-project damages for the Forrest Heights area were estimated using HEC-FDA program and evaluated for three future relative sea level rise scenarios; existing (Future 1), moderate (Future 3), and high (Future 5) relative sea level rise. The existing relative sea level rise condition, as described in the previous section, incorporates relative sea level rise to the base year, 2012, and does not project future relative sea level rise. The moderate and high relative sea level rise functions were used in the program by adding 0.9-feet for the moderate rate and 1.3-feet for the high rate to the existing relative sea level rise curves. Table 6.18-4 summarizes the without-project damages expected for the Forrest Heights area.

Table 6.18-4.
Without-Project Damages for the Forrest Heights Area by Future Scenario

Future Scenario 1	Future Scenario 3	Future Scenario 5
Existing Relative Sea Level Rise	Moderate Relative Sea Level Rise	High Relative Sea Level Rise
$107,550	$127,010	$141,290

6.18.6 List of Measures

- **Measure A - Elevation 17 ft NAVD88**

This option consists of an earthen dike around the Forrest Heights community as shown on the following Figure 6.18-5, along with the levee culvert/interior pump/detention location. The earth dike will be trapezoidal in shape with a 12-foot top width with one foot vertical to three foot horizontal slopes on both sides (1H:3V). For this option the two existing roadway entrances will be ramped over the restored levee. The total length of the levee will be approximately 7900 feet.

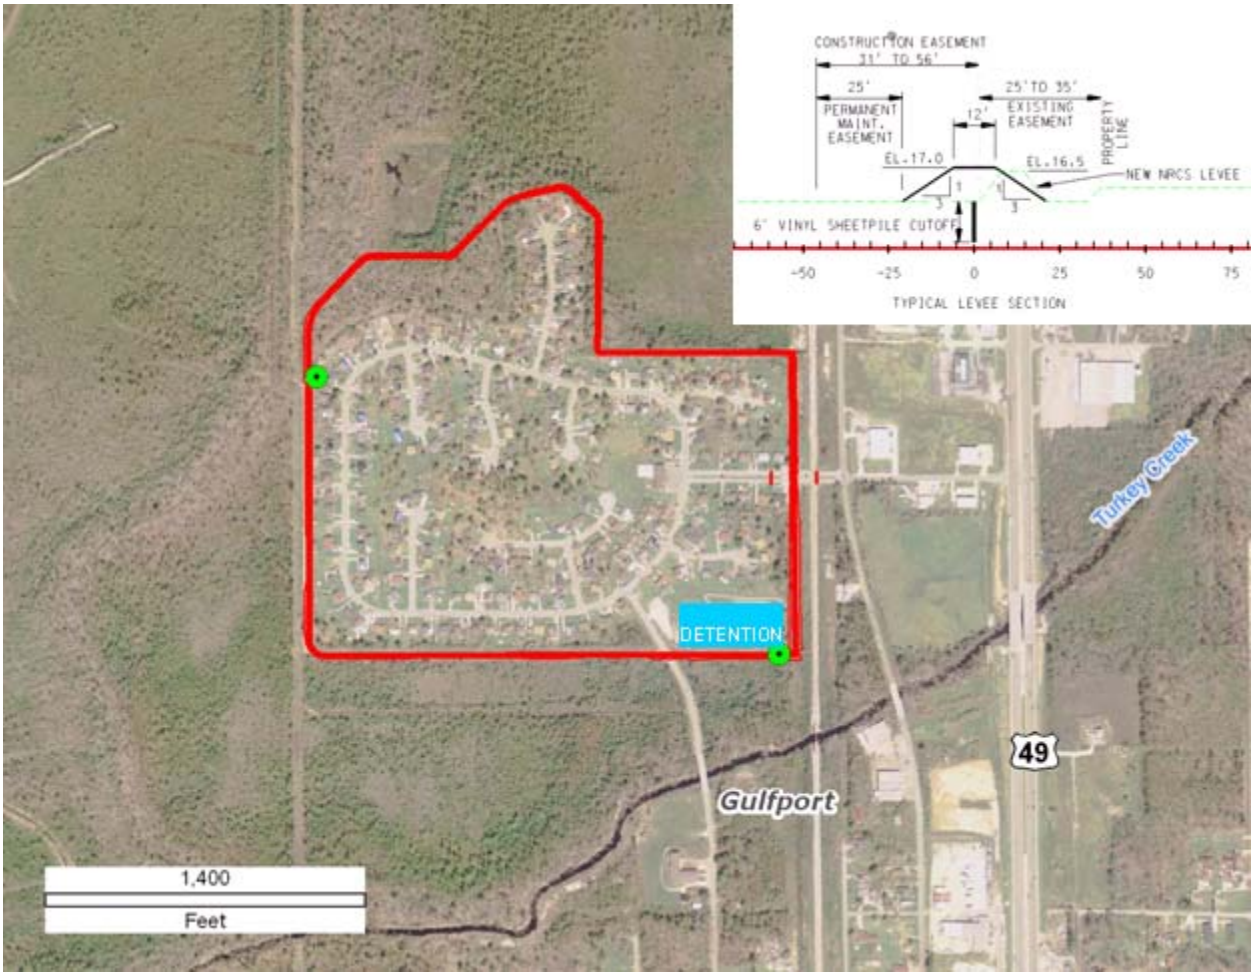

Figure 6.18-5. 17-ft Elevation Levee Alignment with Culvert and Pump/Detention Basin Locations

Levees reduce the storage capacity and overbank flow conveyance of the adjacent floodplain. The reductions in overbank flow area could induce higher water levels upstream. An HECRAS model was used to evaluate the potential for induced damages and solutions. The modeling indicates that selective clearing and snagging would prevent increases in water surface elevations upstream that would occur due the placement of the levees in the floodplain.

The selective clearing and snagging would extend for approximately 4.5 miles from the mouth of Turkey Creek at Bernard Bayou to the upstream limits as shown in Figure 6.18-6. Selective clearing and snagging would remove obstructions such as debris dams and excessive sedimentation that hinders the flow through the Turkey Creek channel. While the selective clearing and snagging component of the plan does not eliminate flooding along Turkey Creek, the plan does reduce flood damages along the creek and at the upper end of the canals at 28th Street. The main purpose of the selective clearing and snagging is to make sure that induced damages do not occur due to the construction of the levee.

The selective clearing and snagging work will follow Stream Obstruction Removal Guidelines established by the American Fisheries Society. Only debris, snags and sediment that obstruct the flow will be removed. Material to be removed includes: 1) fine sediment accumulations that obstruct flows and alter flow patterns; 2) Debris blockages that currently or in the near future cause obstructed flow and altered flow patterns; and 3) Rooted trees that obstruct flow or need to be cleared for equipment access. Access areas that are cleared will be reestablished at the conclusion

of the selective clearing and snagging activities. Some access points, however, may remain for the non-Federal sponsor to use for maintenance activity of the completed project. The existing bank alignment along the entire reach will not be changed, including the downstream reaches of Turkey Creek along the meander bends. Specific reaches to be cleared and snagged will be identified by an interdisciplinary team prior to construction.

Figure 6.18-6. Channel Clearing and Snagging Limits

Damage and failure by overtopping of levees could be caused by storm surges greater than the levee crest. Overtopping failures are caused by the high velocity of flow on the top and back side of the levee. Although significant wave attack on the seaward side of some of the New Orleans levees occurred during Hurricane Katrina, the duration of the wave attack was for such a short time that major damage did not occur from wave action. The erosion shown below in Figure 6.18-7 was caused by approximately 1-2 ft of overtopping crest depth.

Source: ERDC, Steven Hughes

Figure 6.18-7. Crown Scour from Hurricane Katrina at Mississippi River Gulf Outlet (MRGO) Levee in St. Bernard Parish, New Orleans, LA

An overtopping reach of the levee with a revetment at the detention/culvert location would be included in the levee design to prevent overtopping failure. The levee would be protected by gabions on filter cloth as shown in Figure 6.18-8, extending across a drainage ditch which carries water to nearby culverts and which would also serve to dissipate some of the supercritical flow energy during overtopping conditions.

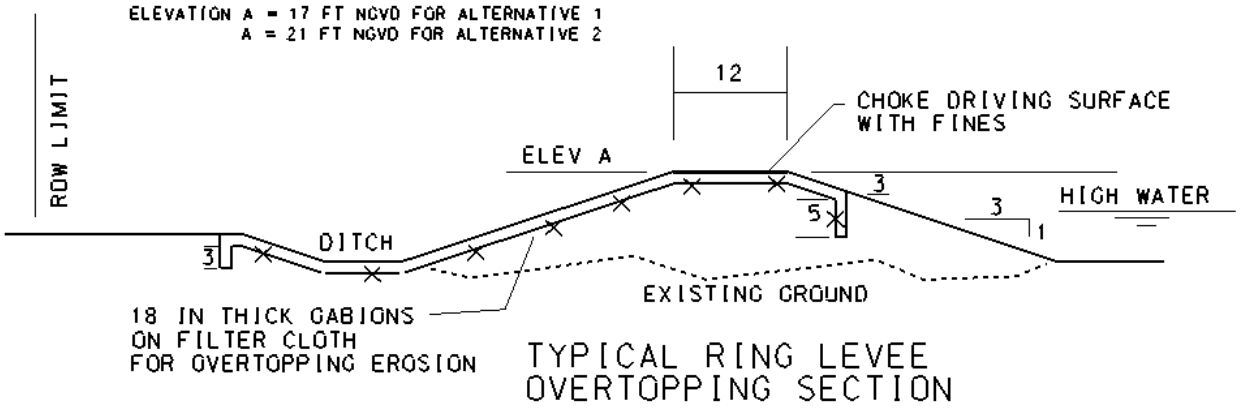

Figure 6.18-8. Typical Levee Overtopping Section

- **Option B - Elevation 21 ft NAVD88**

This option consists of an earthen levee around the entire community of Forrest Heights. The alignment of the levee is generally the same as Option A, above, with the required northern levee portion that would enclose the community within the levee as shown in Figure 6.18-3. The only difference between the description of this option and preceding description of Option A is the height of the levee and the length of the levee culverts. Other features and methods of analysis are the same.

6.18.7 With-Project Conditions

Equivalent annual damages reduced are those damages that are estimated to be reduced with a ring levee measure in place. Table 6.18-5 summarizes the equivalent annual damages reduced and table 6.18-6 summarizes residual damage.

Table 6.18-5.
Summary of Equivalent Annual Damages Reduced

Measure	Damages Reduced Future 1	Damages Reduced Future 3	Damages Reduced Future 5
No Action	$0	$0	$0
Measure A 17FT Levee	$8,860	$10,210	$11.580
Measure B 21FT Levee	$74,340	$89,340	$100,540

Table 6.18-6.
Summary of Equivalent Annual Residual Damages

Measure	Damages Reduced Future 1	Damages Reduced Future 3	Damages Reduced Future 5
No Action	$0	$0	$0
Measure A 17FT Levee	$98,690	$116,800	$129,710
Measure B 21FT Levee	$33,210	$37,670	$40,750

6.18.8 Summary of Costs

The rough order magnitude (ROM) costs for construction and for operations and maintenance are comparative-Level "Parametric Type" estimates and are based on Historical Data, Recent Pricing, and Estimator's Judgment. Quantities listed within the estimates represent Major Elements of the Project Scope and were furnished by the Project Delivery Team. Price Level of Estimate is April 07. Estimates excludes project Escalation and HTRW Cost. Table 6.18-7 summarizes the costs for the levee measures.

Table 6.18-7.
Summary of Costs by Measure for Forrest Heights

Measures	Total Cost to Implement (First Cost) ($)	IDC ($)	Total Initial Cost ($)	Average Annual Implementation Cost ($)	Average Annual O&M ($)	Total Average Annual Costs ($)
(No Action)	$0	$0	$0	$0	$0	$0
Measure A 17FT Levee	$6,100,000	$135,000	$6,235,000	$335,000	$42,000	$377,000
Measure B 21FT Levee	$11,400,000	$252,000	$11,652,000	$626,000	$114,000	$740,000

The implementation costs include 1/ supervision and administration (30 account), 2/ planning, engineering & design (31 account) and 3/ appropriate contingencies. See the Cost Appendix for more detail on the implementation cost breakdowns. Numbers are rounded to the nearest thousand.

6.18.9 Regional Economic Development (RED) Benefits Socioeconomic Impacts using the Economic Impact Forecast System

The purpose of this analysis is to determine the economic impact of the proposed project alternatives on business (sales volumes), income, employment, and population of the local area. Each of the alternatives would affect the local area of Hancock County, Mississippi. The expenditures for the alternatives are estimated to be $6,100,000 for Alternative 1 and $11,400,000 for the Alternative 2. Moreover, the Annual Operation and Maintenance (O&M) expenditures are estimated to be $700,000 for Alternative 1 and $1,400,000 for Alternative 2 (assuming a 50 year period of analysis and an interest rate of 5.375-percent). Tables 6.18-8 through 6.18-11 summarize the EIFS model inputs and outputs for the cost effective measures at Admiral Island.

Table 6.18-8.
EIFS Model Implementation Inputs for the Forrest Heights Area

Local Population	0	0	0

CHAPTER VII. SENSITIVITY ANALYSIS

7.1 Period of Analysis Sensitivity

This section describes the sensitivity of the period of analysis on the evaluation of equivalent annual damage reduction and average annual costs for the various measures. There are two significant drivers inherit in the period of analysis that will be addressed in this section. The first is the effect of relative sea level rise depending on a 50-year or a 100-year horizon and the other is the concept of the time value of money and amortization.

In order to describe the effects of these variables, two specific sites were chosen; Pearlington and Gautier areas. These areas were specifically chosen because they reside in the western and eastern planning units of the state, planning units one and three respectively, and because they have been formulated for the comparison of structural and nonstructural measures. Measures for each area were evaluated using the 100-year and 50-year periods of analysis. The measures included a ring levee at 20-feet NAVD88, a ring levee at 30-feet NAVD88, an ABFE level nonstructural plan (acquisitions and elevate-in-place), a nonstructural plan to a 20-foot NAVD88 elevation, and a nonstructural plan with a 30-feet NAVD88 elevation. These elevations were chosen to develop a cost and benefit curve, and were not assigned a particular event frequency. At some point, the curve would be used to determine the elevation for various frequency events. The evaluation of these measures to determine cost-effectiveness is located in Chapter VI of this appendix.

7.1.1 Effects of the Period of Analysis on Damages

The Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) program was used to calculate equivalent annual without-project damages and equivalent annual damages reduced for the various measures. The HECFDA model calculates equivalent annual damages for a base year and a most likely future year, and then linearly interpolates damages and damages reduced between the years. Figure 7.1-1 depicts this process. The process is the same for a 50-year period of analysis except that the most likely future would be 2061.

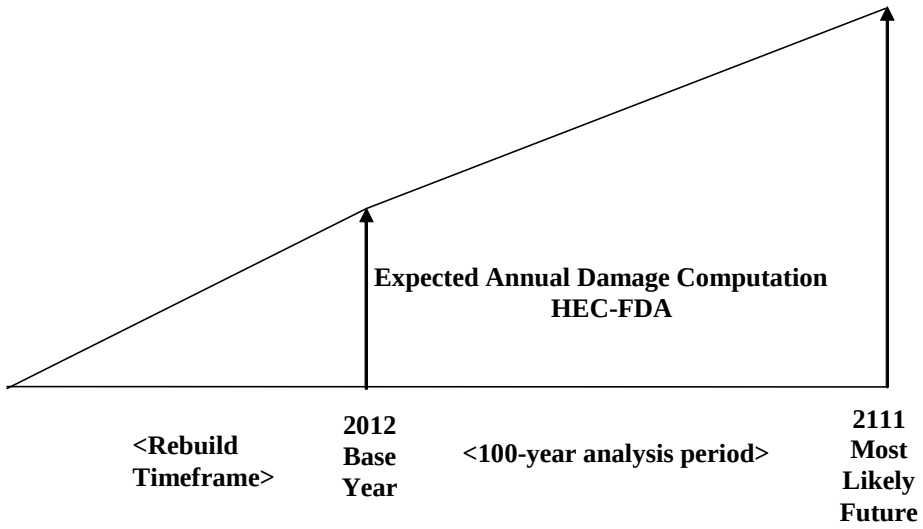

Figure 7.1-1. Calculation of Equivalent annual damages

There are six future without-project scenario conditions that were created for the MsCIP Comprehensive Plan. They are a combination of two different types of redevelopment scenarios with three types of relative sea level rise scenarios. Table 7.1-1 summarizes the six scenarios, which are described in greater detail in Chapter V of this appendix.

Table 7.1-1.
Overview of Future Scenarios

Future Scenario	Redevelopment Type	Relative Sea Level Rise 100-Years	Description
Future Scenario 1	Residential	Historical Only	Rebuild structures as existed pre-Hurricane Katrina with no relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 2	Mixed Residential & Commercial	Historical Only	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, no relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 3	Residential	Expected	Rebuild structures as existed pre-Hurricane Katrina with up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 4	Mixed Residential & Commercial	Expected	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, a up to 2.4-feet relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.
Future Scenario 5	Residential	High Rate	Rebuild structures as existed pre-Hurricane Katrina with up to 3.4-feet of relative sea level rise over the period of analysis. This future scenario applies to all three planning units.
Future Scenario 6	Mixed Residential & Commercial	High Rate	Rebuild structures as existed pre-Hurricane Katrina except at water front where condo/casino rebuild will occur. Also, up to3.4-feet of relative sea level rise over the period of analysis. This future scenario applies only to planning units one and two. Planning unit three would not allow commercial type redevelopment based on local ordinances.

Future Scenarios One and Two are included only to evaluate the effects of relative sea level rise. These Future scenarios will not be used in the evaluation of potential measures. Futures Three, Four, Five, and Six will be the future scenarios by which potential measures will be evaluated depending on the planning unit.

The Pearlington and Gautier areas were on evaluated against future scenarios one, three, and five due to the geographic characteristics, historical development patterns, and political climate of the areas. SAM Engineering Division developed exceedance probability functions for each of the fifty-four planning sub-units; Pearlington is denoted as planning sub-unit six and Gautier as planning sub-unit thirty. The exceedance probability functions were developed by using an approach that combined historical Corps gage data and modeling conducted by the Engineer Research and Development Center (ERDC). The engineering appendix contains more information about the exceedance probability functions.

The exceedance probability function for the base year is the observed/modeled value, and the most like future year is the base year exceedance probability function plus some measure of relative sea level rise depending on the period of analysis. Future without-project scenario one is the full

redevelopment of the area back to pre-Hurricane Katrina levels with no addition for future relative sea level rise. Future without-project scenario three is the same redevelopment scenario as future one with an expected rate of relative sea level rise applied to the most likely future year (2111), and future without-project scenario five is the same redevelopment with a high rate of relative sea level rise included. Table 7.1-2 summarizes the future without-project scenario three and five conditions.

Table 7.1-2.
Details of Future Without-Project Scenarios One, Three, and Five 100-Year and 50-Year Periods of Analysis

Measure	Redevelopment Type	Approximate 100-Year Relative Sea Level Rise	Approximate 50-Year Relative Sea Level Rise
Pearlington Area (Planning sub-unit six)			
Future Scenario One	Redevelopment back to pre-Hurricane Katrina Levels	0.0-feet	0.0-feet
Future Scenario Three	Redevelopment back to pre-Hurricane Katrina Levels	1.8-feet	0.9-feet
Future Scenario Five	Redevelopment back to pre-Hurricane Katrina Levels	3.2-feet	1.3-feet
Gautier Area (Planning sub-unit 30)			
Future Scenario One	Redevelopment back to pre-Hurricane Katrina Levels	0.0-feet	0.0-feet
Future Scenario Three	Redevelopment back to pre-Hurricane Katrina Levels	2.4-feet	1.5-feet
Future Scenario Five	Redevelopment back to pre-Hurricane Katrina Levels	3.8-feet	2.0-feet

By comparing the change in equivalent annual damages, damages reduced, and residual damages for future without-project scenario one under the 100-year and 50-year periods of analysis, the effects of the time value of money can be isolated. This is true because future scenario one has no change in relative sea level rise whether it is being evaluated at 100-years or at 50-years. Thus, the only difference between future scenario one for the 100-year and 50-year is the change in the capital recovery factor. The Capital recovery factor is a ratio that is applied to total present worth damages in order to estimate the average annual value of a number. For damages, it is calculated as:

Average Annual damages = Total Present Worth of Damages x Capital Recovery Factor

Total Present Worth = $\sum_n$ (Cost / (1+ i) ^n)

Capital Recovery Factor (CRF) = i / (1-(1+i) ^-n)

Where:

i = discount rate

n = period of analysis

The capital recovery factor is calculated by the HEC-FDA program based on the user input discount rate (4.875-percent) and the period of analysis (100-years or 50-years). The HEC-FDA program was run for periods of analysis for future without-project scenario one. Without-project damages for the Pearlington area were $11,569,000 and $12,640,000 for the 100-year and 50-year analysis respectively, and without project damages for the Gautier area for future scenario one are

$4,920,000 and $5,376,000 for the 100-year and 50-year period of analysis respectively. This represents a 9.26-percent difference for the Pearlington area and a 9.27-percent difference for the Gautier area for equivalent annual without-project damages. Thus, the effects of a 50-year period of analysis are higher equivalent annual damages than would be expected under the 100-year period of analysis. The same higher effect can be seen for the equivalent annual damages reduced and the equivalent annual residual damages. Tables 7.1-3 and 7.1-4 show the comparison of the damages reduced and the residual damages for future without-project scenario one for the two periods of analysis.

Table 7.1-3.
Equivalent Annual Damage Reduction Comparison of 50-Year Compared to 100-Year Future Without-Project Scenario One Pearlington and Gautier Area Measures

Measure	100-Year Equivalent annual damages ($)	50-Year Equivalent annual damages ($)	Percent Difference 50-Yr to 100-Yr (%)
Pearlington Area Measures			
Ring Levee 20FT	$11,241,000	$12,282,000	9.26%
Ring Levee 30FT	$11,560,000	$12,630,000	9.26%
ABFE Nonstructural	$10,998,000	$12,016,000	9.26%
Gautier Area Measures			
Ring Levee 20FT	$4,378,000	$4,784,000	9.27%
Ring Levee 30FT	$4,897,000	$5,350,000	9.26%
ABFE Nonstructural	$3,104,000	$3,391,000	9.25%

Damages are rounded to the nearest thousand.

Table 7.1-4.
Equivalent Annual Residual Damage Comparison of 50-Year Compared to 100-Year Future Without-Project Scenario One Pearlington and Gautier Area Measures

Measure	100-Year Equivalent Annual Residual Damages ($)	50-Year Equivalent Annual Residual Damages ($)	Percent Difference 50-Yr to 100-Yr (%)
Pearlington Area Measures			
Ring Levee 20FT	$328,000	$358,000	9.15%
Ring Levee 30FT	$9,000	$10,000	11.11%
ABFE Nonstructural	$571,000	$624,000	9.28%
Gautier Area Measures			
Ring Levee 20FT	$542,000	$592,000	9.23%
Ring Levee 30FT	$23,000	$26,000	13.04%
ABFE Nonstructural	$1,816,000	$1,985,000	9.31%

Damages are rounded to the nearest thousand.

Future without-project scenarios three and five are different from future without-project scenario one in that they account for some rate of relative sea level rise over the period of analysis. As previously displayed in table 7.1-2, the 50-year period of analysis would constitute a smaller rate of relative sea level rise than the 100-year period of analysis. This smaller rate, given all other things equal, would mean that the equivalent annual without-project damages, equivalent annual damages reduced, and the equivalent annual residual damages for the 50-year period of analysis would be lower than the 100-year period of analysis. However, the time value of money effect that was described for future scenario one also comes into play for future scenarios three and five, resulting in and upward effect. Thus, there is a simultaneous push upward (time value of money) and downward (relative sea level rise) from these two variables when comparing the equivalent annual damages under a 50-year to the 100-year period of analysis. This can be seen in the effects of the change in equivalent annual without-project damages for future scenarios three and five are displayed in table 7.1-5. For the Pearlington area, the change to equivalent annual without-project damages is 3.24 and -4.01(negative 4.01)-percent for future without-project scenario conditions three and five respectively. The changes for the Gautier are 1.90 and -7.65 (negative 7.65)-percent for future scenarios three and five respectively. The effects of the change in scenario three are dominated by the time value of money factor, causing and increase in equivalent annual damages; where scenario five is dominated by a reduction in relative sea level rise (the difference in a 100-year estimate compared to a 50-year estimate), thus causing a lowering effect.

Table 7.1-5.
Equivalent Annual Without-Project Damage Comparison of 50-Year Compared to 100-Year Future Without-Project Scenarios Three and Five Pearlington and Gautier Area Measures

Measure	100-Year Equivalent annual damages ($)	50-Year Equivalent annual damages ($)	Percent Difference 50-Yr to 100-Yr (%)
Pearlington Area Measures			
Future Scenario Three Without Project Damages	$12,885,000	$13,303,000	3.24%
Future Scenario Five Without Project Damages	$14,205,000	$13,635,000	-4.01%
Gautier Area Measures			
Future Scenario Three Without Project Damages	$5,831,000	$5,942,000	1.90%
Future Scenario Five Without Project Damages	$6,702,000	$6,189,000	-7.65%

Damages are rounded to the nearest thousand.

Table 7.1-6 displays the equivalent annual damage reduction for the 100-year and 50-year periods of analysis for future without-project scenario three and table 7-1.7 for future without-project scenario five. Residual damages, damages that remain even if the measure were to be implemented, are shown in table 7.1-8 for future-without project scenario three and table 7.1-9 for future without-project scenario five.

Damages are rounded to the nearest thousand.

The results of the sensitivity of the period of analysis on future without project scenarios three and five vary by location and plan. As previously noted, this is due to the upward effect of the time value of money and the lowering effect that results from a lesser relate of relative sea level rise for the 50-year period of analysis. The only conclusive evidence that can be deduced from this exercise is that there will be higher residual damages under the 100-year period of analysis as compared to the 50-year period of analysis, and, in some cases, the difference in residual damages are very large.

It is important to note that the 20-feet NAVD88 and 30-feet NAVD88 elevations were fixed point elevations for cost and benefit evaluation purposes only, and not directly tied to a particular frequency event. When implemented to a particular frequency event, an elevation would have to be selected to provide for that level of protection. By using a 50-year period of analysis, the selection of an elevation for a particular event level would be lower than the selection for the same event level

under the 100-year period of analysis due to the difference in relative sea level rise. Thus, if you were to pick the elevation for the 1-percent event under the 50-year period of analysis and relative sea level rise were more like the 100-year period of analysis, the risk of overtopping and increased level of residual damages could be significant.

7.1.2 Effects of the Time Value of Money

7.1.2.1 Average Annual Implementation Cost

Traditionally, the Corps of Engineers reports costs on an average annual basis. Average annual costs are calculated by multiplying the total present worth of costs times the capital recovery factor.

Average Annual Implementation Costs = Total Present Worth of Costs x Capital Recovery Factor

Total Present Worth = Cost / (1+ i) ^n))

Capital Recovery Factor (CRF) = i / (1-(1+i) ^-n)

Where:

i = interest rate

n = period of analysis

Typically, costs are associated to the years they would be expended in should the project be constructed. Those expenditures are then brought back, or present worthed, to the same fiscal year (FY) as the benefits in order for a direct and accurate comparison. At this point in the analysis of the potential measures, the timing of expenditures have not yet been identified; therefore the total implementation cost act as the total present worth of the implementation costs and will be multiplied by the capital recovery factor to get the average annual implementation cost values.

A simple case example is to imagine that a project costs one dollar to implement, or the present worth of the project is one dollar. This is the same whether you chose a 50-year period of analysis or a 100-year period of analysis, thus the changing variable is the capital recovery factor. The capital recovery factors for a 100-year and 50-year period of analysis are 0.049171225 and 0.053722282 respectively. Using the average annual cost equation expressed above the average annual costs of the one dollar project is:

100-Year

$1 x 0.049171225 = $0.049

50-Year

$1 x 0.053722282 = $0.053

This simple comparison shows that the difference in cost for a 100-year period of analysis compared to a 50-year period of analysis is that the 50-year average annual cost is 9.26-percent higher. This result would be expected since the costs are attributed to a shorter period. The everyday example of this is a person saving to buy something. If you save monthly over two years compared to one year, you will have to save less every month to achieve the same goal. Table 7.1-10 shows this effect on the measures for the Pearlington area and the Gautier area. **Note:** Future without-project scenarios have no bearing on the implementation cost of the various measures.

Table 7.1-10.
Average Annual Implementation Cost Comparison of 50-Year Compared to 100-Year Pearlington and Gautier Area Measures

Measure	100-Year Average Annual Costs ($)	50-Year Average Annual Costs ($)	Percent Difference 50-Yr to 100-Yr (%)
Pearlington Area Measures			
Ring Levee 20FT	$4,754,857	$5,194,945	9.26%
Ring Levee 30FT	$5,620,271	$6,140,457	9.26%
ABFE Nonstructural	$19,073,518	$20,838,873	9.26%
Gautier Area Measures			
Ring Levee 20FT	$16,629,708	$18,168,876	9.26%
Ring Levee 30FT	$21,620,587	$23,621,687	9.26%
ABFE Nonstructural	$9,362,201	$10,228,723	9.26%

7.1.2.2 Interest During Construction

Interest during construction is an added economic cost because it is the opportunity cost of having construction monies tied up until the measure becomes fully operational. Since, at this point in the analysis, the length of construction for these measures have not been identified, interest during construction was not calculated for the analyzed Pearlington and Gautier area measures and is not included in the total average annual costs. Further study would be required in order to calculate interest during construction on each of the measures. However, since interest during construction is a function of the discount rate and the period of time it takes to construct the project, it will have no bearing on whether a 100-year or 50-year period of analysis is used, i.e. interest during construction would be the same regardless of the period of analysis.

Average annual operation and maintenance costs for the structural ring levee measures was calculated as two-percent of the contract cost for the structure. This number was provided by MOBILE DISTRICT (SAM) Engineering Division and would not be impacted under a 100-year or 50-year period of analysis. Average annual operation and maintenance costs for nonstructural measures were provided but the Corps of Engineers Nonstructural Flood Proofing Committee (NSFPC) and were based on factors that are not directly affected by the period of analysis.

7.2 First Floor Elevation Uncertainty Sensitivity

The HEC-FDA program is a Monte Carlo based program that allows and compensates for the uncertainty pertaining to multiple structure characteristic inputs. The main uncertainty variables are those pertaining to the exceedance probability function, structure value, content value, and first floor elevation. Initial sensitivity runs on these variables determined that the first floor elevation uncertainty is the most sensitive to change. For that reason, the first floor elevation was chosen for this sensitivity analysis.

In a typical feasibility level study, the first floor elevation of each structure is determined by a survey crew in the field. For the MsCIP Comprehensive Plan Report, the survey of over 130,000 structures was not feasible from a time, labor, and funding perspective. Therefore, a sampling technique was used to estimate the first floor elevation of each structure using a combination of LIDAR data and field estimation of the finished floor above ground elevation. The uncertainty pertaining to the

estimated first floor elevation was found to be 3.52-feet for one standard deviation. This was attained by surveying a two-percent sample, approximately 3,000 structures, using the typical feasibility level survey method and then comparing it to the estimates attained from the LIDAR plus finished floor estimates. Chapter IV describes the inventory sampling process and first floor elevation estimates in greater detail.

Given the nature of sensitivity and the magnitude of the uncertainty pertaining to the first floor elevation, a sensitivity analysis was conducted to determine the extent of influence this variable had on the equivalent annual damages that were estimated for the entire study area. The sensitivity analysis was conducted for the equivalent annual without-project damages for all six future without-project scenarios. Details on those scenarios can be found above in table 7.1.1 or in chapter V of this appendix.

The intent of this sensitivity analysis was to compare the first floor elevation uncertainty in the MsCIP Comprehensive data to the uncertainty expressed in previous Corps studies using more accurate and traditional surveying methods. In order to determine a typical uncertainty that is associated with the standard survey of ach structure, previous Mobile District reports were utilized. Uncertainty pertaining to the first floor elevation used for previous feasibility studies ranged from 0.3-feet and 0.9-feet for one standard deviation. For this sensitivity analysis, the mean of these values (0.6-feet) was used. The future without-project conditions for each of the six scenarios were run with both the 3.52-feet of uncertainty and the 0.6-feet of uncertainty and compared to determine the sensitivity. The following tables show the results of the first floor elevation sensitivity analysis on equivalent annual damages and damages reduced for the Pearlington and Gautier area measures.

Table 7.2-1.
First Floor Uncertainty Sensitivity on Equivalent Annual Without-Project Damages
Pearlington and Gautier Area Measures

Measure	3.52FT Uncertainty Equivalent annual damages ($)	0.6FT Uncertainty Equivalent annual damages ($)	Percent Difference (%)
Pearlington Area Measures			
Future Scenario One Without Project Damages	$11,569,000	$6,950,000	-39.93%
Future Scenario Three Without Project Damages	$12,885,000	$8,856,000	-31.27%
Future Scenario Five Without Project Damages	$14,205,000	$9,586,000	-32.52%

Damages are rounded to the nearest thousand.

CHAPTER VIII. TENTATIVELY-SELECTED PLAN FEATURES

The tentatively-selected system wide plan features for the MsCIP Comprehensive plan, explained in more detail in the Main Report, have multiple levels. Some of the features will be recommended as work for entities other than the Corps of Engineers, some will be recommended for further construction, and some will be recommended for implementation. The list of measures in this appendix which are recommended for further study include the ring levee and nonstructural measures at the Pearlington, Ocean Springs, Gautier, Gulf Park Estates, Belle Fontaine, and Pascagoula/Moss Point areas, as well as further inquiry into the coast wide 20-foot, 30-foot, and 40-foot elevation nonstructural measures. Among the list of tentatively-selected plan features for construction that were analyzed in this appendix include barrier island restoration, beach and dune placement, ecosystem restoration at the Admiral Island, Turkey Creek, Bayou Cumbest, Dantzler, and Franklin Creek areas, the 21-foot elevation levee at the Forrest Heights area, and the acquisition of parcels within high risk areas.

For planning and screening purposes, the analysis in this appendix used a 100-year period of analysis for measures that were determined to be complex in nature such as the barrier island restoration or measures that had a high risk of residual damages due to relative sea level rise such as flood risk management measures. Other measures that were not as complex in nature, such as the beach and dune placement and the ecosystem restoration measures were evaluated at the traditional 50-year period of analysis used in Corps of Engineers studies. In order to show consistency among the plans recommended for construction, those measures that were initially screened at a 100-year period of analysis have been converted to a 50-year period of analysis for costs and benefits and are summarized in table 8-1. The costs in table 8-1 represent Rough Order Magnitude (ROM) utilized for screening. Detailed Micro-Computer Aided Cost Estimating System (MCACES) costs can be found in the cost estimating appendix.

Table 8-1.
Summaries of Benefits and Costs for Measures Recommended for Implementation[1]

	Equivalent Annual Damages Reduced Future 3 (Annual $)	Recreation (Annual $)	Environmental Impacts	Changes in Sales Volume ($)	Changes in Income ($)	Changes in Employment	Total First Cost with IDC ($)[2]	Average Annual Cost (Annual $)
Barrier Island Restoration	$18,028,000	$466,000	$43,618,000 Fishery Losses Avoided	$798,984,000	$167,850,000	4,920	$370,439,000	$20,372,000
Beach and Dune Placement	Moderate Reduction	N/A	736 Functional Habitat Index (FHI) Score	$33,413,200	$7,307,000	208	$15,890,800	$854,000
Acquisition in High Risk Areas	$22,000,000 to $33,000,000	Potential Recreational Opportunities	Potential Restoration Opportunities	$3,238,602,000	$706,330,000	19,452	$447,274,000	$18,532,000
Forrest Heights 21-FT Ring Levee	$89,000	N/A	3.6 Acres Impacted	$30,425,000	$6,440,000	193	$11,652,000	$740,000
Admiral Island Ecosystem Rest.	Increased Surge Storage	N/A	60 Average Annual Functional Units (AAFU)	$49,750,000	$ 11,996,000	301	$24,320,000	$1,364,000
Turkey Creek Ecosystem Rest.	Increased Surge Storage	N/A	1,565 Average Annual Functional Units (AAFU)	$15,237,000	$3,226,000	97	$6,017,000	$370,000
Bayou Cumbest Ecosystem Rest.	Increased Surge Storage	N/A	188 Average Annual Functional Units (AAFU)	$54,073,000	$ 10,546,000	306	$23,870,000	$1,396,000
Dantzler Ecosystem Rest.	Increased Surge Storage	N/A	1,244 Average Annual Functional Units (AAFU)	$ 5,054,000	$ 986,000	29	$1,922,000	$129,000
Franklin Creek Ecosystem	Increased Surge Storage	N/A	516 Average Annual Functional Units (AAFU)	$3,890,000	$ 759,000	22	$1,670,000	$101,000

1/ These measures were analyzed for economic benefits and do not represent the entire tentatively-selected plan features for implementation. See the main report for more detail.
2/ Implementation costs are based on ROM cost estimates at an FY 08 price level and do not include escalation. See the engineering appendix for more details on the costs.
3/ Average annual damages reduced and costs are based on a 50-year period of analysis and an FY 08 discount rate of 4.875-percent. Dollar values are rounded to the nearest thousand.

ADDENDUM A – HEC-FDA DEPTH DAMAGE FUNCTIONS

CHAPTER A-I. OVERVIEW

Damages for assets and contents were calculated using the Hydrologic Engineering Center-Flood Damage Analysis (HEC-FDA) model. Damage of an structure and its contents are estimated as a function of stage, first floor elevation, depth of water in asset, percent of damage at each depth, and the value of the structure and its contents (see equation below). This function derives the stage damage in terms of dollar value damage for the structure and its contents. At each stage, the stage damage for all assets and their contents are aggregated to determine a total damage for each stage. The HEC-FDA model, described in detail in the Economic Appendix, applies a Monte Carlo simulation to the aggregated stage damage to determine Equivalent Annual Damages (EAD). The purpose of this addendum is to detail the depth-damage relationships (percent of damage at each depth) that were used in the HEC-FDA model runs, 2/ why they were used, 3/ how they were developed, and 4/ the uncertainty that is included within the relationships.

Stage Damage ($) = Stage – First Floor Elevation = water depth in structure = % damage x asset/content value

Depth-damage relationships are a mathematical function that describes the extent of damage to an structure and its contents for each foot of water that is deposited into the structure by a storm event. The general premise is that the entire structure and its contents are not damaged by just one foot of water within it, but increase as the water depth within the structure rises. Typically, depth-damage relationships are developed using a combination of observed data that is collected after a storm event and by expert elicitation. Depth-damage relationships take into account multiple variables such as whether the water is fresh water or salt water, the duration the water remains in the asset, the materials that the structure is constructed of, and whether a person or business occupies the asset.

A-1.1 Selection of Depth-Damage Relationships

The depth-damage relationships for assets and contents that were used in the HEC-FDA model runs for the Mississippi Coastal Improvement Program (MsCIP) Comprehensive Plan include generic relationships developed by the Institute for Water Resources and depth-damage relationships developed for the U.S. Army Corps of Engineers, New Orleans District. According to ER 1105-2-100, E-19q. (2), depth-damage relationships for feasibility studies should be developed either based on site-specific data or from comparable floodplain data. For this analysis, site-specific data was not readily available for use given the scope, complexity, and timing constraints pertaining to the MsCIP Comprehensive Plan Report; therefore, comparable floodplain data was used.

For residential structures, generic relationships for residential one-story and two-story assets and their contents are from The Corps of Engineers *Economic Guidance Memorandum (EGM) 01-03, Generic Depth Damage Relationships*. These relationships were developed for nation-wide applicability in flood damage reduction studies for assets without basements.

The depth-damage relationships used in association with commercial, municipal, and mobile home assets and their contents are those that were develop for the Lower Atchafalaya and Morganza Feasibility Studies. These relationships are saltwater short-term duration relationships, meaning that the period of inundation (the time that water is in the asset) is approximately twenty-four hours. The Lower Atchafalaya and Morganza short-duration relationships were specifically chosen because of the vast similarities between structures in Louisiana and the Mississippi Gulf Coast. These

similarities include building code requirements, quality of material and labor used for construction, size, and design, and other attributes that make the Lower Atchafalaya and Morganza short-duration relationships a perfect match for the MsCIP Comprehensive Plan Report. These curves are further described in section 1.4 of this addendum.

A-1.2 Uncertainty

A statistical definition of uncertainty is the 'estimated amount or percentage by which an observed or calculated value may differ from the true value.' Since depth-damage relationships are developed through data sampling and/or by using expert opinion, some amount of uncertainty naturally exists. To account for this uncertainty, each structure and content curve contains uncertainty bounds. For residential assets and their contents, a bell-curve distribution was used in which the mean and the standard deviation were input into the HEC-FDA model, and then the model accounted for two standard deviations of error, or approximately a ninety-five percent confidence level. For commercial and municipal assets and contents, an upper and lower bound surrounds a mean value.

The HEC-FDA model uses Monte Carlo simulation to randomly sample damage percentages at each stage. The random sampling allows for multiple values to be analyzed for depth-damage relationship. For example, one-foot of water depth within a Mobile Home asset, see Table A1-3 below, can equate to structure damage ranging from 42.5-percent to 53.6-percent to the Mobile Home. The Monte Carlo simulation used by the HEC-FDA model will select values within this range and determine a 'typical' damage for that one-foot water depth. Thus, the model incorporates the uncertainty of the depth-damage relationship in this process.

A-1.3 Residential Damage Relationships

Residential assets and their contents were divided into and analyzed as one-story, two-story, and mobile homes as per EGM 01-03. These residential relationships were developed based primarily on the findings of the Flood Damage Data Collection Program. According to EGM 01-03, "Proper planning and evaluation of flood damage reduction projects require knowledge of actual damage caused to various types of properties. The primary purpose of the Flood Damage Data Collection Program is to meet that requirement by providing Corps district offices with standardized relationships for estimating flood damage and other costs flooding that occurred in various parts of the United States in 1996, 1997, and 1998. Damage estimates are based on comprehensive accounting of losses from flood victims' records. The standardized functions represent a substantive improvement over other generalized depth-damage functions such as the Flood Insurance Administration (FIA) Rate Reviews." The residential depth-damage relationships for structure and content are shown in Tables 1, 2, and 3.

Figure A-5. Mobile Home Structure Damage Relationship

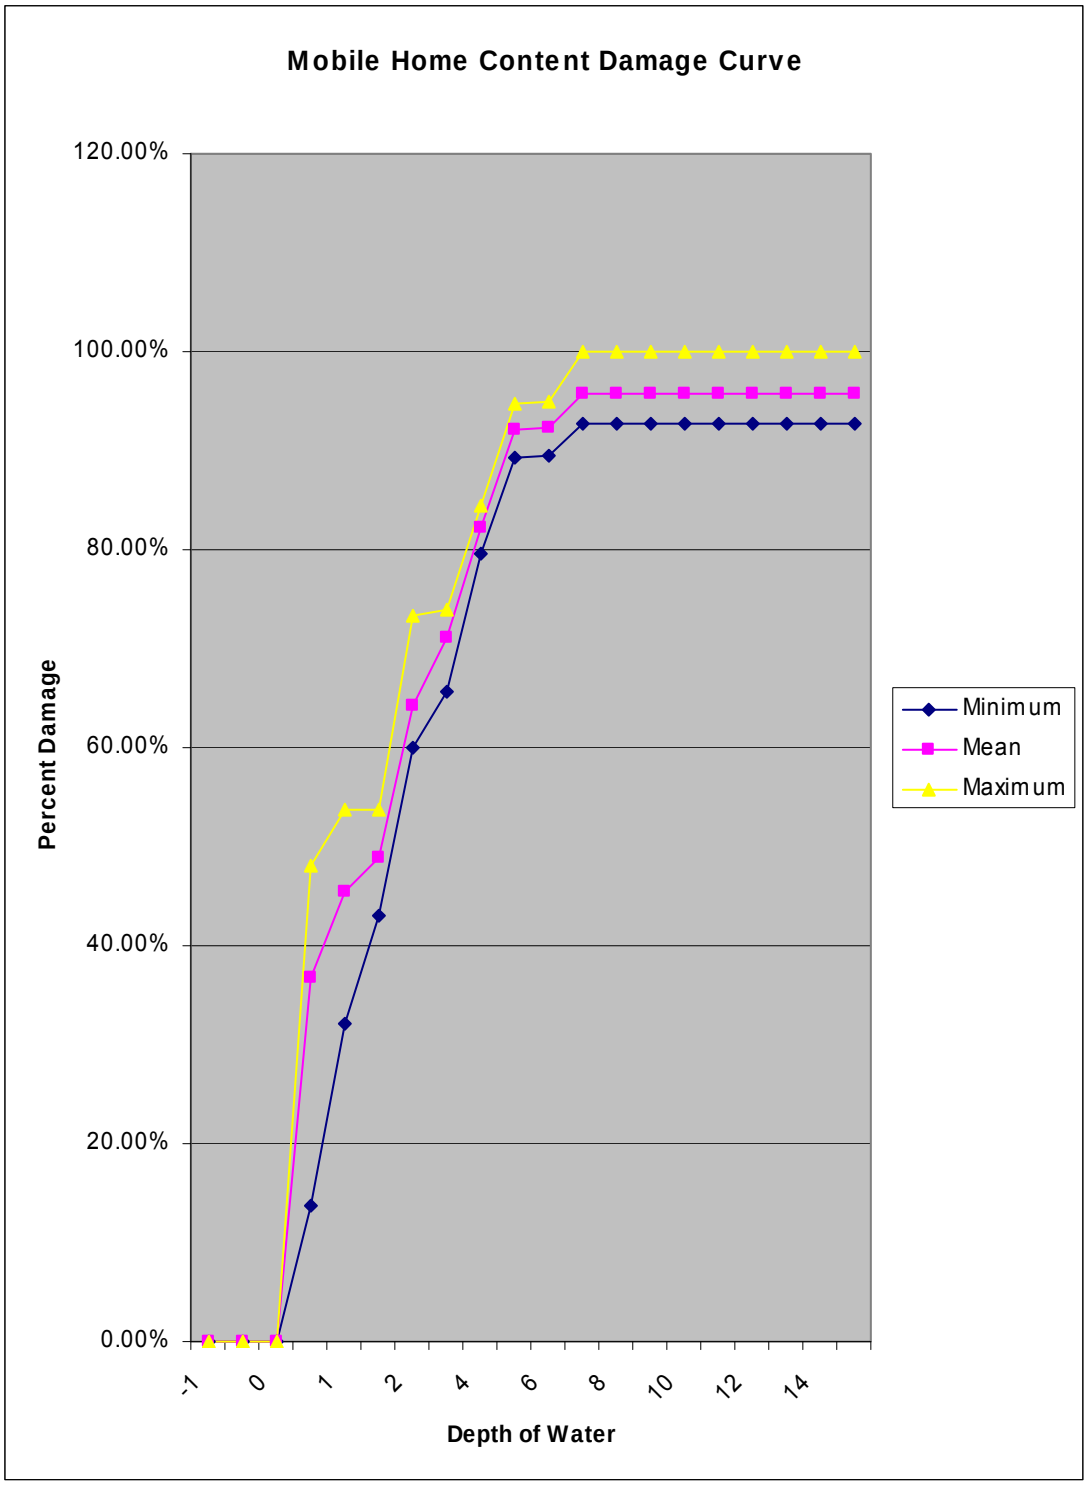

Figure A-6. Mobile Home Content Damage Relationship

A-1.4 Commercial Damage Relationships

Commercial and mobile home structure and content relationships are from the July 1997 final Report entitled Depth-Damaged Relationships for Assets, Contents, and Vehicles and Content-To-Asset Value Ratios (CSVR) in Support of the Lower Atchafalaya Reevaluation and Morganza to the Gulf, Louisiana Feasibility Studies prepared for New Orleans District Corps of Engineers. These relationships are based on field surveys, interviews, and expert panel opinions. Interviews with commercial operators yielded owner/operator estimates of damage that would occur to assets and contents at various flooding levels. Expert panel opinions were based on the "Expert Opinion" method described in the Handbook of Forecasting Techniques (IWR Contract Report 75-7, December 1975) and the Handbook of Forecasting Techniques, Part II, Description of 31 Techniques (Supplement of IWR Contract Report 75-7, August 1977). The panel was asked to determine depth-damage relationships for typical assets in the Lower Atchafalaya and Morganza study areas. The depth-damage relationship is the expected amount of damage either in dollars, or as a percentage of total value for each foot of flooding above or below the first floor of a asset. Commercial structure types were categorized as metal frame, masonry bearing walls, and wood or steel frame walls. However, commercial content categories were divided into the following types: (1) eating and recreation, (2) groceries and gas stations, (3) multi-family residences, (4) repair and home use, (5) retail and personal services, (6) professional business, (7) public, semi-public, and (8) warehouse and contractor services. The commercial depth-damage relationships for structure and content are shown in Tables 4 to 11.

Moreover, each of the eight commercial content categories included a wide variety of business establishments as shown in the following list:

1/ Eating and Recreation: fast food restaurants, full-service restaurants, lounges, bowling alleys, movie theaters, etc.

2/ Groceries and Gas Stations: large and neighborhood groceries, bakeries, candy Stores, wine stores, liquor stores, drug stores, gas stations, convenience stores, and etc.

3/ Multi-Family Residences: garden apartments, high-rise apartments, condominiums, townhomes, motels, hotels, and etc.

4/ Professional Businesses: banks, real estates offices, legal offices, accounting firms, medical offices, veterinary offices, dentist offices, funeral homes, etc.

5/ Public and Semi Public: schools, civic associations, churches, government facilities, utility companies, etc.

6/ Repairs and Home Use: auto repair, watch repair, re-upholstery, home repair, and etc.

7/ Retail and Personal Services: department stores, furniture stores, clothing stores, shoe stores, barber shops, beauty salon, Laundromats, etc.

8/ Warehouse and Contractor Services: transit warehouse, distribution warehouse, storage warehouse, factory, manufacturers, plumbing services, heating and air condition services, carpeting services, etc.

ADDENDUM B – EXPERT ELICITATION ABSTRACT

Institute for Water Resources, U.S. Army Corps of Engineers

Version 1 dated January 30, 2009

COASTAL STORM DAMAGE RELATIONSHIPS BASED ON EXPERT OPINION ELICITATION

(DRAFT)

U. S. Army Corps of Engineers
USACE Institute for Water Resources
Humphreys Engineer Center, Casey Building
7701 Telegraph Road
Alexandria, VA 22315-3868

CHAPTER B-I. ABSTRACT

This report documents the results of the Coastal Storm Damage Workshop on June 5, 6, 2002 in Alexandria, Virginia where expert-opinion was elicited for economic consequence assessment of coastal storm damage. The objectives of this workshop were to discuss and recommend damage relationships needed for predicting structural damage from coastal storms as functions of hazard intensity levels, with associated uncertainties, resulting from erosion, waves, inundation, and their combined effects. Because information on the relationship between residential structural damage and storm parameters is limited, this workshop used expert-opinion as a means of gaining information on these relationships (see Aye 2001). This report describes the results of the workshop both in terms of damage relationships and future information needs identified by the experts at the workshop.

This workshop is part of longer-term research effort whose objective is to develop a peer-reviewed, step-by-step methodology for estimating coastal storm damages. The methodology will be incorporated as part of the inputs to a new hurricane and storm damage reduction estimation model being developed by IWR. The methodology will be able to stand alone for use in Corps' districts or by other national or local agencies including potential incorporation as an option in FEMA's HAZUS model.

CHAPTER B-II. INTRODUCTION

B-2.1 Program Overview

The objective of this research is to develop a peer-reviewed, step-by-step methodology for estimating damages from coastal storms to property and improvements. The methodology will also be incorporated as part of the inputs to a new hurricane and storm damage reduction estimation model being developed by the Institute for Water Resources (IWR). The methodology will be able to stand alone for use in Corps' districts or by other national or local agencies including potential incorporation as an option in FEMA's HAZUS model.

The objective will be achieved using a two-stage process to elicit opinions from experts to develop damage functions to estimate storm damages. The first stage of this process consisted of developing framework to quantitatively describe the damage done to a structure from storm hazards such as inundation, waves, erosion, and wind. Preliminary damage relationships (curves) were also developed. As a starting point for the first stage, the project core team from IWR proposed a “straw man” framework to be modified by a small group of experts. Inputs for this first stage included the models presently in use by Corps' offices (e.g. Wilmington and Jacksonville) and other agencies around the country, as well as a framework that is being developed for this purpose for the Corps’ Wilmington District. Experts were chosen from within the Corps’, from contractors and academics with experience in coastal storm damage, and from the Federal Emergency Management Authority. Although a focus was on the hurricane-prone southeastern U.S., the workshop also included expertise from the North Atlantic and California.

The second stage will involve additional data collection through a full review of the initial framework and relationships by a review team, by Corps' offices, and by the professional community at-large, and from damage data collected in post-storm surveys. Experts will then be convened in a formal expert elicitation to use this additional information to modify the preliminary depth-damage relationships and develop final estimates of likely economic damages from a coastal storm.

B-2.3 Needs and Existing Storm Damage Information

This study was prompted by a widely-perceived need for better information on coastal storm damage relationships. A December 2000 letter from the Assistant Secretary of the Army to the Wilmington District requested a “Corps-wide-survey of damage functions used for all types of structures and the rationale for using them, for hurricane and storm damage reduction projects”. The expectation was that “better guidance can be provided to field offices on the conduct of economic analysis if we have the benefit of … better tools to evaluate hurricane and storm damage projects”. This research seeks to provide these better tools.

In investigating storm damage relationships, available sources of information can be divided into two general categories: 1) data on storm damages and on existing structures, and 2) models of the relationships between storm parameters and damage. Whereas the relationships between storm parameters and damage are the ultimate purpose of this investigation, the relationships need to be grounded in the data on actual storm damages. As background for the research and in preparation for the workshop, the project core team from IWR reviewed coastal damage methodologies from various sources including: Corps Districts in Jacksonville, Wilmington, New Orleans, Mobile, New York, Philadelphia; the HAZUS model - a natural hazard loss estimation methodology developed by the Federal Emergency Management Agency in partnership with the National Institute of Building Sciences; FEMA building performance studies; Federal Insurance claims data; USACE reports on Hurricane Fran and on Shoreline Protection and Beach Erosion Control; state data from Hurricane Opal (FL); the Heinz Center’s Evaluation of Erosion Hazards, and various articles from the open literature (i.e. Budge 1991, King et al. 1991, Ulrich et al. 1994, Kato and Torii 2002, Tomalley et al. 2002).

B-2.4 Use of Expert Opinions

The primary reason for using expert opinions is provide "data" where little or no data exists about an issue or problem. It can also deal with uncertainty in selected technical issues related to a system of interest. Issues with significant uncertainty, issues that are controversial and/or contentious, issues that are complex, and/or issues that can have a significant effect on risk are most suited for expert-opinion elicitation. Here we used an informal, consensus-based elicitation process to promote creative thinking about potential frameworks and problem definition. The value of any expert-opinion elicitation comes from its initial intended uses as a heuristic tool, not a scientific tool, for exploring vague and unknowable issues that are otherwise inaccessible. It is not a substitute to scientific, rigorous research.

The identification of the need for the information developed during the elicitation process and its communication to experts are essential for the success of the elicitation. The need identification and communication should include the definition of the goal of the study and relevance of issues to this goal. Establishing this relevance would make the experts stakeholders and thereby increase their attention and sincerity levels. Relevance of each issue and/or question to the study needs to be established. This question-to-study relevance is essential to enhancing the reliability of collected data from the experts. Each question or issue needs to be relevant to each expert especially when dealing with subjects with diverse views.

The expert-opinion elicitation process can be defined as a formal, heuristic process of obtaining information or answers to specific questions about certain quantities, called issues, such as failure rates, unsatisfactory-performance consequences and expected service life. This process should not be used in lieu of rigorous reliability and risk analytical methods, but should be used to supplement them and to prepare for them. It should be preferably performed during a face-to-face meeting of members of an expert panel that is developed specifically for the issues under consideration. The

meeting of the expert panel should be conducted after communicating to the experts in advance to the meeting background information, objectives, list of issues, and anticipated outcome from the meeting. The different components of the expert-opinion elicitation process are described in Aye (2001).

B-2.5 Recent USACE Expert-Opinion Elicitation Studies

Expert-opinion elicitation is a technique for using a panel of individuals with various areas of specialized knowledge for estimating parameters or addressing issues of interest based on their expertise. The March 2002 expert elicitation conducted by IWR on the Economic Consequence Assessment of Residential Flood Damage is a recent example of use of the technique. Expert-opinion elicitation has also been recently applied by the New Orleans District's study of the Lower Atchafalaya Basin and reevaluation of the Morganza to the Gulf of Mexico feasibility studies, by Vicksburg District's Pearl River study, and by the Sacramento District's Feather River flood damage study. Building contractors, insurance adjusters, home decorators, and other individuals with knowledge of construction, prices, and typical home furnishings were used to estimate depth-damage and content-to-structure value ratios. Details on some of these studies are provided in Aye (1999 and 2001).

B-2.6 Residential Damage Due to Coastal Storms

The scope of this study consists of structural damage to single-family homes from coastal storms. These economic consequences can be described by mathematical functions that relate storm parameters such as wave crest height or the depth of still water flooding to the percent of damage that occurs to structures. The percent damage to structure refers to the percent of the depreciated replacement costs of the structure that is damaged. Coastal storms damage structures through wave action, still water flooding, wave run-up, erosion, and wind. These hazard types are described briefly below.

Waves: Most of the energy delivered to the shore by the ocean originates from the wind acting on the ocean to produce waves. Wave characteristics are determined by the wind direction, wind speed, wind duration, how far the wind blows over water, and how far the wave travels before reaching land. Wave action can cause significant damage to coastal structures. Conventional wisdom is that if breaking waves strike at or above a building's first floor elevation, that structure will be severely damaged. This is the rationale for the National Flood Insurance Program's (NFIP) characterization of a highly vulnerable zone (V-zone) for damage from wave action. The ability to prevent wave damage is considered a major benefit of Corps' shore protection measures. Although FEMA demarks the V-zone as an area subject to breaking waves at least 3 feet high, recent, FEMA-sponsored tests indicate that 1.5-foot waves can break away walls. This research suggests that the V-zone might more appropriately extend to all areas subject to 1.5-foot high breaking waves.

Stillwater flooding: Storms can cause inundation of structures with still water either through overtopping of a dunes system (coastal flooding) or through flood waters coming from the bay side of a coastal island (bay-side flooding). Coastal flooding implies still-water level flooding of structures because of overtopping of a dune system or storm surge breaking through from the coastal side and inundating beach areas. A major benefit of Corps' shore protection measures may be reduced coastal flooding damages. Bayside flooding implies still water level flooding of structures, with flooding coming from the bayside. Natural or man-made structures may have prevented flooding from storm surge on the coastal side of an island, but high seas inundated structures from the bay or backside of an island. Structures on the bayside of islands are frequently constructed with a lower level of flood protection than structures across the island on the oceanfront. For example bayside

houses may be built lower to the ground whereas oceanfront houses might be raised on piles. Damage from bayside flooding is generally not reduced through shore protection measures.

Erosion: On average, the nation's shorelines are receding at an annual rate of slightly more than one foot per year, although rates vary significantly across regions and across shoreline types. In addition to long-term erosion, erosion during a storm may destroy a dune and undermine shorefront structures. The extent of damage will depend on the amount of storm-induced erosion at the structure and structural characteristics such as foundation and piling embedment. Damages from storm-induced erosion can be significant, regardless of the long-term erosion rate or whether natural processes rebuild the dune in the months following a storm. Corps shore protection measures can provide significant reduction in damages attributable to erosion. Because erosion causes beaches to narrow over time, it is a major factor to consider in conducting a life cycle analysis of project benefits and costs.

Wave Run-up: Wave run-up is the upper level reached by a wave on a beach or coastal structure, relative to still-water level (Coastal Engineering Manual, 2002). Wave run-up applies pressure on a structure in both a vertical and horizontal direction and is a function of the water depth and the square of the water velocity. Wave run-up ceases to be a damage factor when breaking waves attack a structure.

Wind Damages: High winds associated with storms can cause significant damages to structures both on the coast and much further inland. High winds and associated flying projectiles can damage doors, windows or roofs. This damage to the integrity of the structure may combine with high winds to cause severe damage or structural failure. Such breaching also allows rainwater damage to the structure. Most of the damages from Hurricanes Andrew, Inky, and Hugo were caused by wind and wind-related rainwater as opposed to waves, flooding, wave run-up, or erosion. Because Corps' projects do not significantly affect the wind speed of storms, wind damage is not reduced through shore protection measures. Nonetheless, wind damage plays a significant role in life cycle cost analysis for Corps' storm damage reduction projects.

CHAPTER B-III. PARTICIPANTS

B-3.1 Requirements

The IWR project core team has the lead responsibility for achieving the project objectives, but relied on input from a larger, working group of experts to develop appropriate damage relationships. The working group represented Corps' Districts that had been active in shoreline protection projects and represented different geographic regions. In addition, it included outside experts from the Federal Emergency Management Agency, universities, and the private sector who had expertise in coastal storm damage assessment.

B-3.2 Participants

A list of the IWR project core team and working group for the workshop is below.

PROJECT CORE TEAM

Affiliation	Name	Role
IWR	Stuart Davis	Project Leader
IWR	Hal Cardwell	Project Leader
IWR	David Moser	IWR Program Manager

FEMA	Paul Tertell	Outside Technical Advisor

CHAPTER B-IV. WORKSHOP RESULTS

B-4.1 Straw man Coastal Storm Damage Framework

The starting point for discussions of coastal storm damage processes was a "straw man framework" for structural damage estimation that was put forth by the IWR project core team. The straw man framework assumes as known, the physical parameters of the area and of the storm. These parameters include surface water elevation, ground elevation, and shoreline type, wave heights, storm-induced erosion depth. Also assumed known are structural characteristics such as location, foundation type, height of lowest supporting beam of structures including their location. Long-term erosion is considered by progressively moving the shoreline landward, therefore increasing the storm-induced erosion and inundation potential from subsequent storms. Economic losses (damages) due to land lost are outside the scope. Wind damages are estimated outside of this framework; this estimate will be used to modify damage to structures from coastal flooding and erosion as appropriate. We also assume the surface water elevation accounts for bay-side flooding and dune breaches.

Inundation: Damage to both contents and structures from wave run-up, breaking waves, and still water flooding is assumed to be captured through the use of FIMA[5] V-zone curves for all areas that experience breaking waves of 1.5 ft above the lowest structural horizontal member of the structure. For areas that experience less than 1.5 feet of flooding, FIMA A-zone curves will be used for structure damage.

[5] The Federal Insurance and Mitigation Administration (FIMA – formerly the Federal Insurance Administration - FIA) developed and uses depth-damage curves to estimate actuarial premiums for flood insurance. FIMA has two sets of curves, A-zone curves for riverine and coastal areas without high wave velocity, and V-zone curves for coastal areas that are expected to experience wave action. FIMA defines the V-zone as those coastal areas expected to experience a 3-foot high breaking wave.

Storm-induced erosion: A curve relating damage to the depth of vertical erosion at the center of building will be developed for various foundation types. This curve will be applied for sandy beaches with small dunes (as defined by FEMA). An additional relationship for high dunes and sandy bluff shoreline types will describe storm-induced damages from near-vertical erosion scarps.

Combined Damage vectors: The total damage to a structure will be the sum of the inundation damages and the storm-induced erosion damages, with the total not to exceed the value of the structure.

B-4.2 Revised Framework

Discussion at the workshop produced consensus on a revised framework for structural damage estimation. Once the damage hazards were identified, the experts focused on determining the appropriate storm variable that would relate to damage for each hazard type. For example, depth of water above the walking surface for the lowest main floor was selected as the best variable to relate to still water flooding damages. This is the X-axis in a depth (or other variable) versus damage curve. The experts then agreed on the number of relationships that would have to be developed to properly predict damages to different foundation types (e.g. slab on grade or pile) or materials (wood, concrete, masonry) were appropriate for each damage hazard. Discussion then moved to different ways to combine the damages across hazards, and how to account for regional differences in shorelines, with a focus on estimating damages to bluffs. We describe the discussions and decisions in this section. Appendix A contains results in the form of quantified relationships (curves) for storm damages.

B-4.2.1 Inundation Damage

For damages from still water inundation the workshop determined that the appropriate storm variable to use was the “Depth of water above the walking surface of the lowest main floor”. Although damages to the floors of a structure occur before the water depth reaches the walking surface, using the depth of water surface is an easier variable to use for data collection. **Structural damages that occur from inundation of the floors at slightly lower depths can be included by assigning positive values to damages when depth of water above the walking surface is negative.**

The workshop determined that damages from inundation also depend on the foundation type, on material, number of floors, and, for structures on piles, on the existence of ground-level enclosures. Separate relationship (although using the same X-axis) would need to be developed for each of the following cases:

- Wood frame with piles (with & without enclosures – small medium and full)
- Wood frame without piles
- Concrete & masonry with piles (with & without enclosure – small medium and full)
- Concrete & masonry without piles
- Number of floors (1, 1.5 and 2)

The workshop considered various existing data sources to quantify the relationships for inundation. These data sources included FIMA coastal A-zone curves, curves from New Orleans District for structures on piles and on piers, and curves issued by the Corps in 2000 based on post-flood surveys of actual damages in various parts of the United States.

B-4.2.2 Waves Damage

For damages due to breaking waves the workshop determined that the appropriate storm variable to use was the "difference between the top of wave (crest) and the bottom of the lowest horizontal member". The workshop considered using the walking floor elevation as the datum for comparison with the top of the wave height for consistency with the measure suggested for inundation. However the workshop decided that the framework would be clearer and more rigorous if it used the bottom of the lowest horizontal member as the reference point because it is at this point that waves can start to damage the structure. If practical considerations preclude measurements of the bottom of the lowest horizontal member, this value can be estimated based on the elevation of the walking surface.

The workshop determined that damages from inundation also depended on the foundation type for structures on piles and on the existence of ground-level enclosures. Separate relationships (although using the same X-axis) would need to be developed for each of the following cases:

- Structures on piles (with & without enclosures – small medium and full)
- Structures not on piles

B-4.2.3 Wave Run-up Damage

The workshop concluded that damages from wave run-up were attributable to the "Difference between the top of water and the bottom of the lowest horizontal member, and its velocity at the seaward face of the structure". The force applied by wave run-up could be described as directly dependent on the depth of the water and the square of the velocity. Forces would likely act in both a horizontal and vertical direction and be measured in lbs/linear foot. However the workshop participants did not feel that the there was enough known about the damage from wave run-up to determine an appropriate storm variable to use, and opted to delay development of a damage relationship as a long-term need.

B-4.2.4 Erosion Damage

For damages from storm-induced erosion, the workshop determined that the appropriate storm variable to use both for structures with shallow foundations and ones on piers was the "percent of footprint compromised." Shallow foundation structures were defined as structures that are on slabs or on piers. Houses on bluffs that experience erosion can be considered as structures with shallow foundations. When a shallow foundation experiences vertical erosion such that it loses support from the ground, the foundation is compromised. Six inches of vertical erosion or undermining has been conventionally considered to cause a loss of support. Whereas the workshop participants felt that this definition was relatively straightforward for shallow foundations, the selection of a variable for deep or pile-supported foundations was more contentious.

The distinction was made between a structure that was undermined by erosion and one that had its foundation "compromised". Whereas for structures on shallow foundations undermining (six vertical inches of erosion) is equivalent to compromised, pile structures can be extensively undermined with little or no damage. In these cases the entire footprint could experience vertical erosion of six inches yet no damage would occur because, although undermined, the erosion does not compromise the ability of the foundation to support the structure. Conversely, a compromised pile can be defined as one whose remaining embedment depth renders it ineffective against lateral forces such as wind and waves. Using, as the independent variable (X-axis) the "percent of footprint compromised" would allow correct categorization of damages done to a pile-support house that, because of erosion, might have its entire footprint in the surf zone (and hence undermined), but yet had minimal damage because its foundation was not compromised. The workshop noted that relating storm

parameters to the percent of footprint compromised would be difficult and likely be regionally and structurally specific. Comment: This percent of footprint compromised is pretty useless to predict damage from a storm unless this can be predicted from the extent of vertical erosion at the structure. I don't think there will be any model that keeps track of all piles of a pile-founded structure. We will have to make assumptions about where piles are located and the extent of embedment.

Because the appropriate storm variable was defined so broadly, the workshop only called for two separate relationships to be developed for erosion damages: one for shallow foundation and one for deep foundations (piles). More relationships may need to be developed as definitions of "footprint compromised" are developed for specific regions and projects.

B-4.2.5 Combining Damages

Because a structure may be damaged by more than one of the four storm damage hazards identified by the workshop, a methodology must be developed for how to combine the damages. The Straw man Framework proposed a simple additive combination with a constraint that the total damages to a structure could not exceed its value. The can be expressed as %A + %B. A more commonly used rule for combining damages is to simply use the maximum percent damage from any hazard, or Max [%A, %B]. Whereas the first rule assumes that there is no common damage caused by different hazards, the latter rule assumes the other extreme - which no damage occurs that is not covered by the most damaging hazard. A third rule to consider would be the sum of the hazard percentages minus their product: %A + %B -%A%B. This framework was used in the Portland District and is akin to the probability of occurrence at least one of two independent events A and B.

The workshop concluded that the combination rule must be dependent on the types of hazard that cause damages. If both waves and inundation cause damage the workshop suggested the rule be to only use the damages caused by waves (this is consistent with FEMA's V-zone definition). If both erosion and inundation cause damage the proposed rule is to use the sum of the damages minus their product. Similarly, if both erosion and run-up cause damage the rule is to use the sum of the damages minus their product. For the case where both run-up and erosion cause damages, the workshop proposed two definitions, one for shallow foundation structures, where the rule is to use the maximum of the two damages, and one for pile foundation structures where the rule is to use the sum of the damages minus their product. We summarize these relationships below for the various cases of combination

Case 1 – Inundation + Waves	%W
Case 2 – Run-up + Waves	%W
Case 3 – Inundation + Run-up	will not occur
Case 4 – Inundation + Erosion	%I + %E - %I*%E
Case 5 – Run-up + Erosion	%R + %E - %R*%E
Case 6 – Waves + Erosion	Max %W, %E (shallow foundation)
	%W + %E - %W*%E (pile foundation)

These cases cover all likely combinations of hazards because a structure would not be subject to both moving water (run-up) at the same time as still-water inundation, and waves damages would subsume run-up as it does inundation damages. The workshop noted as a long term need, better information as to when to "switch" from the inundation damage curve to the wave damage curve. Similarly this could be one area of investigation when determining the run-up damage relationships.

Discussion at the workshop included concerns on how to calibrate damage relationships from multiple sources, and noted that the structure should permit direct data collection for the calibration

B-4.2.6 Coastlines with of Bluffs

Storm damages on coastlines with bluffs differ from those on a beach and dune coastline. Inundation is not an issue for bluffs, and neither are waves or run-up except as they promote erosion. Also, all foundations on bluffs can be treated as shallow foundations or slabs, because erosion from a bluff will undermine a deep pile foundation in the same way as a shallow foundation. Failure of a bluff can be from top to bottom or from bottom to top.

B-4.2.7 Long-term and Short-term Needs / Next Steps

The following table summarizes the long-term and short-term needs and future steps in this area:

Priority	Long-term and Short-term Needs / Next Steps
High	Methodology (including authority) for post storm data collection to determine flood conditions during event and erosion conditions at the end of an event.
High	Define/issue guidance for "Compromised" regional Differences
High	Beach profile translation
High	Contents
High	Land Loss/estimated value
High	Post storm data – wave crest water level elevations, lower limit (elevation) of wave damage.
High	Pre-storm building inventory
High	Collection of Existing loss information (including analysis of data from Fran)
Medium	Wave damage height threshold (1.5 ft vs 3 ft) – When do we abandon the inundation curve? How far inland is wave damage an issue?
Medium	RUN-UP RELATIONSHIPS - HOW TO QUANTIFY (WEST COAST)
Medium/Low	Sedimentation damage during inundation
Medium/Low	Duration of inundation
Low	Bluff Erosion processes
Low	Curves/response of engineered buildings, and other non residential structures
Low	Salt versus fresh water inundation damage

CHAPTER B-VI. DAMAGE RELATIONSHIP DETAILS

The following figures contain the details of the damage relationships developed in the workshop. The "Proposed" curve represents the experts' median estimate of damages, whereas the upper and lower represent estimates of the range of the damages. Here, 75 percent of the time damages will be less than the "Upper" curve and 25 percent of the time damages will be lower than the "Lower" curve. For the inundation curves, the upper and lower bounds were set equivalent to the estimates used by New Orleans district for structures on piers (N.O. pier), and by the FIMA coastal A-zone curves, respectively. For damages from inundation, the workshop only developed curves for the selected cases noted below. The workshop assumed that estimates for inundation damages in structures with partial enclosures would flow from the curves developed here. Likewise all curves apply for single story houses.

ADDENDUM C – PARKING AND ACCESS

CHAPTER C-I. USER FEES, PUBLIC ACCESS AND PARKING

This addendum describes the public access, and parking for the length of the beach construction evaluated in the Mississippi Coastal Improvement Program (MsCIP) Comprehensive Report. This parking and access analysis was conducted in accordance with ER 1165-2-130 "Water Resource Policies and Authorities – Federal Participation in Shore Protection" dated 15 June 1989. The data provided in this addendum was collected through field verification.

According to ER 1165-2-130, "Unless the protection of privately-owned beaches is incidental to protection of public beaches (paragraph 9), they must be open to all visitors regardless of origin or home area, or provide protection to nearby public property to be eligible for Federal assistance. Items affecting public use are… 1/ parking, 2/ access, and 3/ user fees." Typically, these items serve a dual purpose of both identifying the basis for federal participation and to justify the recreation benefits of the proposed shoreline protection project. For the MsCIP Comprehensive Report, the shoreline protection measures (Line of Defense 2) have zero net recreational benefits, in other words, the future with project condition recreation benefits are the same as the future without project recreation benefits. Since there is no claim on recreation benefits, this analysis is not intended to show public availability for justifying benefits claimed, but merely to show whether or not there is sufficient availability to use that would warrant federal participation.

C-1.1 Parking

The coast of Mississippi is approximately 70 miles long and spans Hancock (planning unit 1), Harrison (planning unit 2) and Jackson Counties (planning unit 3), from west to east respectively. Within each county there is public parking and access to the beach. There are a total of 3,730 free parking spaces along the beach in the three-county study area.

The Coast of Hancock County is approximately 16 miles long. Beach Blvd spans 8 miles of the eastern portion of Hancock County's coast. Along Beach Blvd there are 592 free parking spaces, both in lots and along the street. The beach can be accessed without significant hindrance from virtually anywhere along South Beach Blvd.

The Coast of Harrison County is approximately 25 miles long. Highway 90 spans the entire coast of Harrison County. Along Highway 90 there are 2,788 free parking spaces, both in lots and along the street. The beach can be accessed without significant hindrance from virtually anywhere along Highway 90.

The Coast of Jackson County is approximately 29 miles long. There are a few roads which run along various portions of the coast. Some of these roads have parking either on the street or in lots. There are a total of 350 free parking spaces. In areas where there is both beach and road along the coast, the beach can be accessed without significant hindrance.

Data on the parking areas for each of the three counties are displayed separately in the tables below. Table C1-1 displays data for Hancock County. Table C1-2 displays data for Harrison County. Table C1-3 displays data for Jackson County. Each table begins with the parking area furthest west

in the county that it represents and ends with the parking area furthest east in the same county. Following the tables are maps of the study area and images of some parking areas.

Figure C1-6. Example Jackson County Parking Lot.

C-1.2 Access

Sufficient access to the public beach exists throughout the three planning units. Under both future without-project and future with-project conditions, the three planning units have access points that run along the entire length of beach in either the form of a board walk or a step down directly from the seawall. These access points are all on the right-of-way for the major road that abuts the beaches including North and South Beach Boulevard in planning unit one and U.S. Highway 90 in planning unit two. Planning unit three contains a combination of direct step downs from the seawalls that run along various sections and walkovers for those sections of beach that require them. All of the access points are on public and are accessible to all visitors on an equal basis at no charge. Figures 1-7, 1-8, and 1-9 illustrate examples of access points to the public beaches in the three planning units.

C-1.3 User Fees

User fees are sometimes charged to the public at beaches in order to recoup the costs of maintaining the beach. Per ER 1165-2-130, “A reasonable beach fee, uniformly applied to all, for use in recovery of the local share of project costs is allowable. Normal charges made by concessionaires and municipalities for use of facilities such as bridges, parking areas, bathhouses, and umbrellas are not construed as a charge for the use of the Federal beach project, if they are commensurate with the value of the service they provide and return only a reasonable profit. Fees for such services must be applied uniformly to all concerned and not as a prerequisite to beach use.” For the beaches in the three planning units in the MsCIP Comprehensive Plan, no fees are anticipated to be charged by the local community.

C-1.4 Conclusion

The results of the analysis indicate that the project meets the requirements of being open 'to all users on an equal basis', and there is sufficient parking and access for the entire length of shoreline protection projects within the three planning units in Mississippi to warrant federal participation. The analysis showed that there are 592 available parking spaces in Hancock County, 2,788 parking spaces in Harrison County, and 350 parking spaces in Jackson County. All spaces are located within a quarter mile of an access point and there is sufficient access to the public beaches either through boardwalk/seawall direct access (planning units one and two) or carefully located access points/crossovers (planning unit 3) along the entire length. User fees are not currently charged to anyone for use and are not anticipated should a project be constructed.

DRAFT

February 2009

Mississippi Coastal Improvements Program (MsCIP) Hancock, Harrison, and Jackson Counties, Mississippi

Appendix C Real Estate

FOREWORD

This document is one of a number of technical appendices to the Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan and Integrated Feasibility Report and Environmental Impact Statement.

The Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan Integrated Feasibility Report and Environmental Impact Statement provides systems-based solutions and recommendations that address: hurricane and storm damage reduction, ecosystem restoration and fish and wildlife preservation, reduction of damaging saltwater intrusion, and reduction of coastal erosion. The recommendations contained in the Main Report/EIS also provide measures that aid in: greater coastal environmental and societal resiliency, regional economic re-development, and measures to reduce long-term risk to the public and property, as a consequence of hurricanes and coastal storms. The recommendations cover a comprehensive package of projects and activities that treat the environment, wildlife, and people, as an integrated system that requires a multi-tiered and phased approach to recovery and risk reduction, irrespective of implementation authority or agency.

Figure 1. The MsCIP Study Area

The purpose of the Comprehensive Plan Report is to present, to the Congress of the United States, the second of two packages of recommendations (i.e., the first being the “interim” recommendations funded in May 2007, and this “final” response, as directed by the Congress), directed at recovery of vital water and related land resources damaged by the hurricanes of 2005, and development of recommendations for long-term risk reduction and community and environmental resiliency, within the three-county, approximately 70 mile-long coastal zone, including Mississippi Sound and its barrier islands, of the State of Mississippi.

This appendix, the Main Report/EIS, and all other appendices and supporting documentation, were subject to Independent Technical Review (ITR) and an External Peer Review (EPR). Both review processes will have been conducted in accordance with the Corps “Peer Review of Decision Documents” process, has been reviewed by Corps staff outside the originating office, conducted by a Regional and national team of experts in the field, and coordinated by the National Center of Expertise in Hurricane and Storm Damage Protection, North Atlantic Division, U.S. Army Corps of Engineers.

The report presents background on the counties that comprise the Mississippi coastline most severely impacted by the Hurricanes of 2005, their pre-hurricane conditions, a summary of the effects of the 2005 hurricane season, problem areas identified by stakeholders and residents of the study area, a summary of the approach used in analyzing problems and developing recommendations directed at assisting the people of the State of Mississippi in recovery, recommended actions and projects that would assist in the recovery of the physical and human environments, and identification of further studies and immediate actions most needed in a comprehensive plan of improvements for developing a truly resilient future for coastal Mississippi.

This appendix contains detailed technical information used in the analysis of existing and future without-project conditions, in the development of problem-solving measures, and in the analysis, evaluation, comparison, screening, and selection of alternative plans, currently presented as tentatively-selected recommendations contained in the Main Report/EIS.

Each appendix functions as a complete technical document, but is meant to support one particular aspect of the feasibility study process. However, because of the complexity of the plan formulation process used in this planning study, the information contained herein should not be used without parallel consideration and integration of all other appendices, and the Main Report/EIS that summarizes all findings and recommendations.

The Real Estate Appendix identifies and describes the lands, easements and rights-of-way (LER) required for construction, operation and maintenance of the proposed projects. Further, the Real Estate Appendix describes the estimated LER value, together with the estimated administrative and incidental costs attributable to providing project LER, and the acquisition process.

The report is not written to the full feasibility level of detail and defers issues pertaining to borrow and disposal sites and facility/utility relocations for further study during Pre-Construction, Engineering and Design (PED) Phase when more specific information is available. At that time those Real Estate Plans for projects recommended for further study will be revised to incorporate new data and information.

REAL ESTATE SUMMARY

The Real Estate Appendix is written to support the Mississippi Coastal Improvements Program (MsCIP) - Comprehensive Report. The Real Estate Appendix discusses the land requirements associated with each of the different alternatives studied for long term protection of the Mississippi Coastline that includes portions of Hancock, Harrison and Jackson counties. The alternatives under consideration which have real estate requirements are identified as Lines of Defense 1, 2, 3, and 4 along with Nonstructural Acquisition and Ecosystem Restoration areas. It is noted that the Bayou Cumbest and Turkey Creek Ecosystem Restoration areas lay completely or partially within the proposed buy out areas. Although included in the buy out estimates, a separate real estate cost estimate is provided for each of these alternatives in the event a stand alone ecosystem restoration project is recommended.

Table RES-1 identifies the alternatives evaluated by Real Estate, and provides a cost for real estate acquisition for the given alternative. The total cost for each alternative includes an estimated cost for land/improvements, relocation payments, and administrative costs to acquire lands and provide relocation assistance services. Mobile District obtained land records tax data bases for 2005 from the tax assessors' offices in Jackson, Harrison, and Hancock Counties, and provided the data bases to Savannah District Real Estate. Mobile District also provided digital shape files of the various alternatives included in the study. From the counties' data bases and the digital shape files, the Savannah District Spatial Engineering Section designed a web based GIS program which includes a footprint for each alternative. Spatial Engineering wrote a program to generate a data base that includes the tax information for each parcel impacted by a given alternative.

Due to the magnitude of the project and the vast amount of data considered, a number of assumptions were made in compiling the Real Estate costs. The numbers of impacted parcels for the LOD 4 Option A, B & C alternatives varied. The process began by looking at parcels individually to make a determination of approximately what percentage of the parcel may be impacted by the footprint for construction of the berm or levee. As changes in the alternatives occurred, it became apparent that it was not feasible to continue the analysis on a parcel by parcel basis.

Based on the first parcel by parcel analysis completed on more than 2,000 parcels, a determination was made to estimate subsequent real estate takings based on a percentage factor. The total number of properties impacted for a given alternative was firm. However, an assumption was made that the land/improvements valuation would be based on a take of approximately 65% after allowing for the partial takings for those properties impacted by the alternative. While costs are based on assessed values from the 2005 tax year, an appraiser completed a market study using approximately 135 comparable sales from the three coastal counties. All sales used occurred in the first quarter of 2007. From these sales an "adjustment factor" for each county was established. The sales indicated post Katrina real estate values were approximately double the pre-Katrina values and the adjustment factors for each county ranged from 1.75 - 2.50 percent. For planning purposes, this adjustment factor was used to bring the assessed values more in line with 2007 "market values".

An assumption was also made that there would be no relocation cost included for those landowners or tenants where there were structures valued at less than $3,000. It was considered likely that in most cases any structure under $3,000 may be an outbuilding or carport so these should not be included. There may be some mobile homes with an assessed valued under $3,000, but this is thought to be a minimal number. For those parcels where the 2005 tax data indicated there was an improvement valued over $3,000, the value of that improvement and a relocation cost for a displacee are included even though the improvement may have been destroyed by Katrina. This was

based on the assumption that the improvement would likely be rebuilt by the time acquisition for the project is implemented.

A clear distinction could not be made in all cases as to whether a benefit cost for residential or business relocation may apply, so an average cost of $28,000 is used as a "relocation payment" for parcels that were identified with pre Katrina improvements across all alternatives. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

The Acquisition alternative included 34 separate reaches and a total of 33,191 impacted parcels for all the reaches. The Ecosystem Restoration areas for the Turkey Creek and Bayou Cumbest pilot projects have a total of 74 parcels. For these alternatives no adjustments for partial takings were made. One hundred percent of the adjusted values for the land and improvements was used for estimating cost. Relocation costs were considered for every landowner/tenant where there was a structure valued at $3,000 or greater with the same reasoning as stated above and the average "relocation payment" of $28,000 was used.

Administrative costs for land acquisition are based on a cost of $22,500 per parcel. This includes both Federal and Non-Federal Costs. Administrative cost for relocation assistance under Public Law 91-646 is $7,500 per displaced family/business. Total Real Estate acquisition costs for each measure are rounded to the nearest thousand, and include land costs, relocation costs and administrative costs.

It is likely that costs can be refined during the Pre-Construction, Engineering and Design Phase when plans and specifications are available for a recommended plan. A Real Estate Supplement (RES) will be prepared for each authorized component once the real estate requirements have been sufficiently identified during PED. The RES will be submitted to CESAD-PDS-R for approval. The RES will provide updated information as to final real estate requirements for a particular component and will include updated data on the real estate values and costs since the majority of the costs and values contained herein should not be relied upon beyond calendar year 2008. A Real Estate Relocation Plan should also be prepared during PED for each authorized component requiring relocations or displacement of individuals and/or businesses. The Relocation Plan will investigate the availability of replacement housing within a specified radius and any unique or unusual problems that should be considered.

Table RES-1.
Real Estate Summary of Costs

Alternative	Purpose	County	Impacted Parcels	RE Costs
LOD1 Offshore Barrier Islands Options A-G	Off-shore Breakwater		5	$19,000
LOD2 Beach/Dune Construction	HSDR	Hancock		$19,000
LOD2 Beach/Dune Construction	HSDR	Harrison		$19,000
LOD2 Beach/Dune Construction	HSDR	Jackson		$19,000
LOD3 Pearlington Ring- Option A 20	Flood Damage Reduction	Hancock	111	$8,883,000
LOD3 Pearlington Ring - Option B 30	Flood Damage Reduction	Hancock	120	$9,340,000
LOD3 Bay St. Louis Ring Option A 20	Flood Damage Reduction	Hancock	42	$120,246,000
LOD3 Bay St. Louis Ring Option B 30	Flood Damage Reduction	Hancock	576	$156,364,000
LOD3 Elevated Roadway	Flood Damage Reduction	Hancock	427	$44,939,000
LOD3 Elevated Roadway	Flood Damage Reduction	Harrison	1,031	$502,215,000
LOD3 Forrest Heights Levee Option A 17	HSDR Flood Damage Reduction	Harrison	67	$2,571,000
LOD3 Forrest Heights Levee Option B 21	HSDR Flood Damage Reduction	Harrison	67	$2,649,000
LOD3 Elevated Roadway	Flood Damage Reduction	Jackson	137	$39,005,000
LOD3 Ocean Springs Ring Option A 20	Flood Damage Reduction	Jackson	197	$43,609,000
LOD3 Ocean Springs Ring Option B 30	Flood Damage Reduction	Jackson	576	$119,542,000
LOD3 Gulf Park Estates Ring Option A 20	Flood Damage Reduction	Jackson	354	$31,458,000
LOD3 Gulf Park Estates Ring Option B 30	Flood Damage Reduction	Jackson	399	$34,051,000
LOD3 Gulf Park Estates Ring Option C 20	Flood Damage Reduction	Jackson	521	$55,002,000
LOD3 Gulf Park Estates Ring Option D 30	Flood Damage Reduction	Jackson	561	$58,603,000
LOD3 Belle Fontaine Ring Option A 20	Flood Damage Reduction	Jackson	228	$19,366,000
LOD3 Belle Fontaine Ring Option B 30	Flood Damage Reduction	Jackson	297	$25,774,000
LOD3 Belle Fontaine Ring Option C 20	Flood Damage Reduction	Jackson	286	$26,711,000
LOD3 Belle Fontaine Ring Option D 30	Flood Damage Reduction	Jackson	359	$33,260,000
LOD3 Gautier Ring Option A 20	Flood Damage Reduction	Jackson	313	$56,977,000
LOD3 Gautier Ring Option B 30	Flood Damage Reduction	Jackson	354	$66,585,000

Table RES-1.
Real Estate Summary of Costs (continued)

Alternative	Purpose	County	Impacted Parcels	RE Costs
LOD3 Pascagoula Ring Option A 20	Flood Damage Reduction	Jackson	1,075	$237,004,000
LOD3 Pascagoula Ring Option B 30	Flood Damage Reduction	Jackson	1,203	$256,517,000
LOD3 Pascagoula Ring Option C 20	Flood Damage Reduction	Jackson	1,175	$278,147,000
LOD3 Pascagoula Ring Option D 30	Flood Damage Reduction	Jackson	1,321	$297,899,000
LOD3 Pascagoula Ring Option E.20	Flood Damage Reduction	Jackson	2,964	$520,145,000
LOD3 Pascagoula Ring Option F 30	Flood Damage Reduction	Jackson	3,076	$533,059,000
LOD3 Pascagoula Ring Option G 20	Flood Damage Reduction	Jackson	3,138	$574,040,000
LOD3 Pascagoula Ring Option H 30	Flood Damage Reduction	Jackson	3,253	$584,742,000
LOD4 Inland Barrier Option A 20	Flood Damage Reduction	Hancock	426	$66,177,000
LOD4 Inland Barrier Option B 30	Flood Damage Reduction	Hancock	484	$74,262,000
LOD4 Inland Barrier Option C 40	Flood Damage Reduction	Hancock	537	$81,107,000
LOD4 St Louis Bay Surge Barrier Options A-C	Flood Damage Reduction	Hancock & Harrison	8	$1,110,000
LOD4 Inland Barrier Option A 20	Flood Damage Reduction	Harrison	1,512	$253,268,000
LOD4 Inland Barrier Option B 30	Flood Damage Reduction	Harrison	1,688	$271,797,000
LOD4 Inland Barrier Option C 40	Flood Damage Reduction	Harrison	1,927	$300,446,000
LOD4 Inland Barrier Option D 20	Flood Damage Reduction	Harrison	568	$58,266,000
LOD4 Inland Barrier Option E 30	Flood Damage Reduction	Harrison	1,916	$298,748,000
LOD4 Inland Barrier Option F 20	Flood Damage Reduction	Harrison	76	$8,917,000
LOD4 Inland Barrier Option G 30	Flood Damage Reduction	Harrison	189	$20,801,000
LOD4 Inland Barrier Option H 40	Flood Damage Reduction	Harrison	209	$28,271,000
LOD4 Inland Barrier Option I 20	Flood Damage Reduction	Harrison	225	$23,938,000
LOD4 Inland Barrier Option J 30	Flood Damage Reduction	Harrison	171	$25,351,000
LOD4 Back Bay of Biloxi Surge Barrier Options A-C	Flood Damage Reduction	Harrison & Jackson	8	$1,767,000
LOD4 Inland Barrier Option A 20	Flood Damage Reduction	Jackson	323	$58,506,000
LOD4 Inland Barrier Option B 30	Flood Damage Reduction	Jackson	361	$66,571,000
LOD4 Inland Barrier Option C 40	Flood Damage Reduction	Jackson	404	$76,231,000
Nonstructural Acquisition	Flood Damage Reduction	Hancock	17,845	$4,241,808,000
Nonstructural Acquisition	Flood Damage Reduction	Harrison	10,912	$2,722,752,000
Nonstructural Acquisition	Flood Damage Reduction	Jackson	4,434	$775,345,000
Ecosystem Turkey Creek Option A	Ecosystem Restoration	Harrison	13	$1,101,000
Ecosystem Turkey Creek Option B	Ecosystem Restoration	Harrison	8	$752,000
Ecosystem Turkey Creek Option C	Ecosystem Restoration	Harrison	5	$350,000
Ecosystem Bayou Cumbest	Ecosystem Restoration	Jackson	61	$4,807,000

CHAPTER 2. THE REAL ESTATE REPORT

2.1 Statement of Purpose

This report is tentative in nature and is to be used for planning purposes only. The report is written based on specific data from Mobile District and the tax assessors' offices in Hancock, Harrison and Jackson Counties, MS. There may be modifications to the plans that occur during Pre-Construction, Engineering and Design phase, thus changing the final acquisition area(s) and/or administrative and land cost. The Real Estate Appendix is intended to support the Comprehensive Report for the Mississippi Coastal Improvements Program. Due to the scale of the project, the Real Estate Appendix is formatted to include a separate Real Estate Plan (REP) for each of the different measures that are formulated. The Statement of Purpose will not be repeated in each REP. The author of this report has viewed the general Project areas. The State of Mississippi is the non-Federal sponsor for the project. Date of this report is November 2007.

2.2 Study Authority

The Coastal Mississippi Comprehensive Study was authorized by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005, which states: "For an additional amount for "Investigations" to expedite studies of flood and storm damage reduction related to the consequences of hurricanes in the Gulf of Mexico and Atlantic Ocean in 2005, $37,300,000 to remain available until expended: ***Provided,*** **That using $10,000,000 of the funds provided, the Secretary shall conduct an analysis and design for comprehensive improvements or modifications to existing improvements in the coastal area of Mississippi in the interest of hurricane and storm damage reduction, prevention of saltwater intrusion, preservation of fish and wildlife, prevention of erosion, and other related water resource purposes at full Federal expense: *Provided further,* That the Secretary shall recommend a cost-effective project, but shall not perform an incremental benefit-cost analysis to identify the recommended project, and shall not make project recommendations based upon maximizing net national economic development benefits; *Provided further*, That interim recommendations for near term improvements shall be provided within 6 months of enactment of this act with final recommendations within 24 months of this enactment:"**

2.3 Authorization for Entry for Construction

After the non-Federal sponsor completes its acquisition effort and prior to issuance of the solicitation for each construction contract, an informed, authorized, and accountable official of the non-Federal sponsor must execute and provide the district a written Authorization for Entry to all land, easements or rights -of-way (LER) that the Government determined the non-Federal sponsor must provide for that contract. The authorization form must also recite that the non-Federal sponsor is vested with sufficient title and interest in such LER. Further, the non-Federal sponsor must also provide the district with a Certificate of Authority that recites that the official signing the Authorization for Entry form on behalf of the non-Federal sponsor has the authority to furnish such authorization to the Government. Again, rather than including the form in each REP, the form will be included in the Real Estate Appendix as Exhibit "A", and the exhibit will be referenced in the REP.

2.4 Assessment of Non-Federal Sponsor's Real Estate Acquisition Capability

For cost shared projects, a thorough assessment of the non-Federal sponsor's legal and professional capability and experience to acquire and provide the LER for the construction, operations and maintenance of the project, including its condemnation authority and quick-take capability is required. The Capability Assessment checklist must be completed and included as part of the REP. Rather than including the checklist in each REP, the checklist will be included in the Real Estate Appendix as Exhibit “B”, and the exhibit will be referenced in the REP. For this study, this assessment will be made during PED.

2.5 Acquisition Schedule and Management Plan

2.5.1 Acquisition Implementation/Management Plan

The acquisition of lands required for a cost shared project is the responsibility of the Non-Federal Sponsor. It is recommended that an Acquisition Implementation and Management Plan (AIMP) be prepared. This plan should outline the necessary steps required to successfully implement and execute the acquisitions. It should include staffing requirements, field office requirements, contracting requirements and schedules identifying milestones to meet completion dates. This plan should be developed jointly with participation from real estate division, the non-federal sponsor and the project manager to ensure adequate time for acquisition and to meet the schedule for advertisement for construction. A lead time of at least six to nine months prior to the estimated date for the availability of the appropriations should be allowed for preparation of the AIMP. It should be noted that on fast track acquisitions, there are several preliminary acquisition activities that can be accomplished during the PED phase such as surveys, title and appraisal requirements. If these activities are scheduled correctly, the acquisitions can be initiated as soon as the appropriations are made available thus saving 6 – 12 months from the acquisition schedule.

2.5.2 Title/Ownership of Lands Acquired

In cost shared projects, the project sponsor is responsible for acquiring real estate required for the project. Since the Non-Federal Sponsor would be required to operate and manage all lands acquired for the project, title to these lands would be acquired in the named of the sponsor. In the event the Federal Government performs the acquisition of lands, the lands would be acquired in the name of the sponsor. In this instance acquisition of LER by the Government on behalf of the sponsor will be by written agreement between the Government and the non-Federal sponsor.

2.6 Mitigation Lands

Implementation of structural plans would require placement of fill within parts of wetlands in Coastal Mississippi. Overall, structural measures have been developed in ways that avoid or minimize wetland impacts. See section 4.1.7, Mitigation Measures in the Environmental Appendix for a discussion on project impacts and measures for mitigation. Land costs for mitigation are not reflected in the Real Estate Appendix as the plan is to purchase credits from a mitigation bank. the cost of the mitigation credits is included in the Environmental Appendix. The cost presented in the Environmental Appendix does not include real estate administrative costs; these costs would be minimal since the purchase of credits from mitigation banks does not involve acquiring a real interest in land. There could be administrative costs incurred for document preparation. Although specific

mitigation sites have not been selected, for estimation purposes a cost of $5,500 per acre is based on costs to buy credits from established mitigation banks in the Mississippi coastal area. It is noted that LERRD credit is not given for mitigation credits that may be purchased for a project. The cost to purchase mitigation credits is considered as a construction cost.

2.7 Zoning

Title 17 of the Mississippi Code is legislation that enables the counties and municipalities within the proposed project area to establish land use zoning ordinances for their jurisdictions to fulfill the goals and objectives of their comprehensive plans. Potential relocations and redevelopment being considered in the project may affect some current residential and commercial zoning in the counties and may require variances or re-zoning of those areas for project implementation. Zoning ordinances can be used to limit development in certain high-hazard areas or areas with sensitive environmental resources. In areas where no development has taken place (vacant land) or where development has been largely removed (total loss areas), zoning or rezoning of the property could accomplish project objectives by limiting or prohibiting future development. Property devoid of structures only retains its basic land value as dictated by market forces. That land value is influenced to some extent by the natural hazards that may endanger any development that would be constructed on the property. In the case of the study area, there are vast numbers of privately-owned tracts where the structure has been totally destroyed leaving only a concrete slab or wood pilings from the previous foundation. In these cases, rezoning the property for other land uses more adaptable to and compatible with the natural hazards may accomplish program objectives. Zoning of high-risk properties bordering the coast and some of the inlet areas could be used to reduce the incidence of damages to certain types of development or all development.

Any rezoning of vacant land after purchase of at-risk properties for the project would be entirely up to the local jurisdictions in accordance with the floodplain ordinances and any executed agreements for project cooperation. Section 4.5.4 in the Nonstructural Appendix provides an in-depth discussion on Land Use Regulation and Zoning for those counties and municipalities in the project areas.

2.8 Borrow Areas

Section 1.5 in the Engineering Appendix gives detailed information on the borrow sites being considered for use in construction of the project. Section 1.5.5 discusses the on-shore borrow areas which are permitted sites. A table is given for each county that lists the sites and type materials available. A map shows the general location of the sites. Section 1.5.6 describes the offshore borrow areas proposed for use. Section 1.5.7 describes the inland river system sand (dredged material) that is in disposal areas. Diked disposal areas along the Black Warrior - Tombigbee River system and the Tennessee-Tombigbee Waterway are available for use. A map of the disposal areas and tables listing the sites and type real estate interest acquired in the sites are included. In summary the proposed borrow sites are a mix of permitted commercial sites and disposal sites for which the Government either owns or holds an easement interest. Current estimates for borrow material indicate that sufficient sources are available for construction without having to acquire additional sites from private landowners. However should any requirements be identified for acquisition of additional borrow or disposal sites from private landowners, they would be considered part of the LER, and the responsibility of the non-federal sponsor to acquire. The sponsor would have to comply with any approval processes required by the respective county governments for using lands for new borrow or disposal sites.

2.9 Induced Flooding

Lines of Defense 3 and 4 incorporate the use of levees and barriers in the structural measures proposed for storm damage reduction. When it rains, excess rainfall can be trapped behind the levees and can induce flooding even in the absence of a hurricane. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. The design of the levees includes flap gates, culverts, pumping stations and drainage ditches to aid in water drainage and to channel excess runoff to either gated culverts or pumping stations which will transfer the excess flow to the outside of the levee thereby minimizing induced damages. Detailed modeling of all the interior sub-basins for all the areas was not possible for this report; therefore the exact extent of the ponding for extreme events is not precisely defined. However, in some of the areas, existing storage could be adequate to pond water without causing damage, even without pumps. In other areas that do have pumps, some rise in interior water during interior events greater than the 10-yr rain could occur, but may not cause damage. The design rationale is based on the minimum facility concept, and economic tradeoffs between induced flooding and pumping provisions were not examined. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas. No induced flooding is anticipated as a result of any of the tentatively selected plans. However, should there be a later determination that there will be induced damages for a given measure, a takings analysis will be prepared, the appropriate real estate interest to be acquired will be identified and the real estate estimate will be revised accordingly.

2.10 Utility/Facility Relocations

The term “relocation” shall mean providing a functionally equivalent facility to the owner of an existing utility, cemetery, highway or other public facility or town when such action is authorized in accordance with applicable legal principles of just compensation or as otherwise provided by Federal statute or any project report or House or Senate document referenced therein. Providing a functionally equivalent facility may take the form of adjusting, altering, lowering, raising, or replacement and attendant removal of the affected facility or part thereof. It is important to note that relocation assistance under Public Law 91-646 relates specifically to displaced persons, and should be distinguished from the separate concept of facility or utility relocations

The REP normally contains a description of the facility or utility relocations that must be performed including information regarding the general nature of the impact to each facility or utility; the identity of the owners of the affected facilities and utilities; the purpose of the affected facilities and utilities; whether the owners have compensable real property interests in the land on which the impacted portion of the facility or utility is located; the conclusions reached in an identified Preliminary or Final Attorney's Opinion of Compensability prepared in support of the relocations determinations; whether special legal authority or direction affects relocation classification [for example, the project's authorizing legislation or reports referenced therein; Section 111 of the River and Harbor and Flood Control Act of 1958 (33 U.S.C. §633)]; and other information relevant to the proper identification and performance of relocations necessitated by construction, operation, or maintenance of the project.

Due to level of study in this project, information about specific "relocations" is unknown. In general, it is known that roads would have to be ramped up at intersections for the proposed ring levee projects and that some public utility lines will have to be relocated. The Town of Moss Point in Jackson County has some municipal facilities that would need to be relocated. Each potential utility/facility relocation will be evaluated to determine relocation requirements and possible problems associated with the relocation. Once this assessment is made, the LERRD cost can be adjusted to reflect addition of the utility/faculty relocation cost which are currently included as a construction cost. Any

relocation requirements will be identified during PED along with the required supporting documentation and estimated cost. Utility/facility relocations can add cost to the project and need to be factored into the acquisition schedule timeline.

2.11 Navigation Servitude

For those lands required for construction that lay below the mean high water mark, navigation servitude will apply. Navigation servitude is the dominant right of the Government under the Commerce Clause of the U.S. Constitution (U.S. CONST. Art.I,§8,cl.3) to use, control and regulate the navigable waters of the United States and the submerged lands hereunder for various commerce-related purposes including navigation and flood control. In tidal areas, the servitude extends to all lands below the, mean high water mark. In non-tidal areas, the servitude extends to all lands within the bed and banks of a navigable stream that lie below the ordinary high water mark. The determination of the availability of the navigation servitude should be made on a case by case basis and consists of a two -step process. First the government must determine whether the project serves a purpose that has a nexus to navigation. Purposes recognized by the courts to have the nexus include navigation, flood control and hydroelectric power. If determined that such a nexus exists, then the second step is to determine whether the land at issue is located below the mean or ordinary high water mark of a navigable watercourse. As a general rule, the Government does not acquire interests in real property that it already possesses or over which its use or control is or can be legally exercised. Therefore, if the navigation servitude is found to be available as a result of application of the process described in subparagraph b of this paragraph, then the Government will generally exercise its rights hereunder and, to the extent of such rights, will not acquire a real property interest in the land to which the navigation servitude applies. Generally, it is the policy of the U.S. Army Corps of Engineers (USACE) to utilize the navigation servitude in all situations where available, for cost shared and full Federal projects. The determination of availability will be made during PED.

CHAPTER 3. LINES OF DEFENSE (LOD)

3.1 Line of Defense 1 - Offshore Barrier Islands

3.1.1 Project Description

The barrier islands of Mississippi are located 10 to 15 miles south of the mainland. Currently, there are five islands in the chain that extends for 45 miles west from a point south of the Alabama – Mississippi state line along the coast as shown in Figure 3.1.1-1. Currently, Ship Island exists as two islands separated by a shallow sand bar. It was breached during Hurricane Camille in 1969 and remains today as West and East Ship Island. Two maintained navigation channels pass through the chain of islands. The Gulfport channel passes near the west end of West Ship Island and the Pascagoula channel passes near the west end of Petit Bois Island. The present day location of the channels prevents any further westward migration of either island. All of Petit Bois, Horn, and Ship Islands and part of Cat Island are within the boundaries of the Gulf Islands National Seashore under jurisdiction of the National Park Service (NPS) as shown in Figure 3.1.1-2. The approximate western two thirds of the island is owned by the United Sates of America. The remaining portion of the island is in private ownership among multiple owners of record. In most cases, the boundary extends one mile from the shore of the island. Petit Bois and Horn Islands have also been designated as Wilderness Areas by the U.S. Department of the Interior and have a higher degree of protection than the other islands. Project construction will be on those lands within the boundaries of the Gulf Islands National Seashore and will not impact private lands.

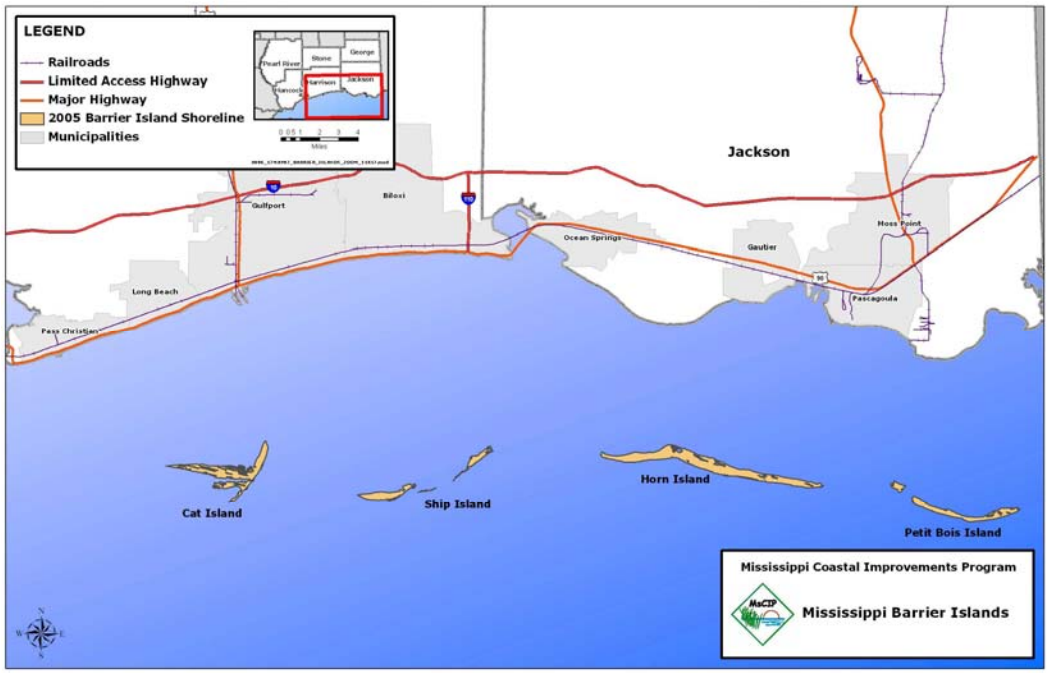

Figure 3.1.1-1. Location of the Mississippi Barrier Islands

Figure 3.1.1-2. Boundaries of the Gulf Islands National Seashore

Data shows that the islands have lost approximately 20 to 25 percent of their land mass since pre-Camille times. Figures 3.1.2.1-1 through 3.1.2.1-4 in the Engineering Appendix illustrate the changes in the footprints of the islands from pre-Camille to post-Katrina. The islands have been heavily influenced by the various hurricanes including even the lower intensity ones. Hurricane George, in 1998, even though a small hurricane, proved to be devastating to the islands due to heavy erosion from waves. Many of the higher dune systems on the islands were destroyed and much of the elevation the islands once had is gone. Most of the islands are now very susceptible to over-wash during storms. Another result of being submerged during Hurricane Katrina was the loss of much of the maritime pine forest that existed on the islands. The trees, mostly now dead from the salt water submergence, played a major role in preventing erosion both from wind and any surges against the islands. Modeling efforts have concluded that over a wide range of storms, there would be some protection provided to the eastern coast of Mississippi along the Jackson County shoreline if the islands are in the pre-Camille condition. The options considered for restoration of the offshore barrier islands are listed in Table 3.1.1-1.

Table 3.1.1-1.
Options for Offshore Barrier Islands

Option	Measure
Option A	Restore Island Footprint
Option B	Replenish Sand in Littoral Zone, Inland Source
Option C	Replenish Sand in Littoral Zone, Inland & Offshore Sources
Option D	Environmental Restoration w/2-foot Dune
Option E	Environmental Restoration w/6-foot dune
Option F	Environmental Restoration of Sea Grass Beds
Option G	Restoration of Ship Island Breach

Several approaches to restoration of the islands were considered. Option A proposes to add new land mass to the islands by using sand dredged and transported from an off-shore location. This sand would come from the St. Bernard Shoals located about 45 miles south of the barrier islands. The shaping of the sand into beaches, dunes and marsh areas will not affect the existing islands other than that narrow strip of land that will form the boundary between the existing island and the new land mass. This option can be used in combination with other options under this line of defense should it be desired to restore habitat on the existing islands. Restoration of Ship Island to a pre-Camille configuration includes closing the post-Katrina, 4-mile long breach to a 2000-foot width and with elevation 20.0 dunes, along with some rebuilding of the other islands to a larger land area. As the new land mass is added to the existing islands, portions of the new island will be planted with various types of vegetation to provide habitat and to aid against erosion.

To increase the size of the footprint of each island and restore them back to a pre-Camille footprint will involve several different operations, some of which can take place concurrently. The source of sand that has been designated as the potential borrow area will require additional investigation using both geophysical techniques and physical sampling. The sand is expected to be in submerged shoals that will have to be located and mapped prior to any removal of the sand. This will be completed during design and before the construction begins.

Each of the islands will require that a “dump basin” be excavated by dredging before any sand is transported from the borrow areas which are located offshore about 45 miles south of the islands. These basins are required due to the depth of the water which is too shallow for the dredges to approach the islands. The basins will typically be located about one mile from the beach of the respective island where sand is being added to surrounding waters. These basins will be of sufficient size to allow a large quantity of sand to be stored after being bottom dumped from a hopper dredge. The material dredged from these basins is anticipated to be unsuitable for placement on the islands and is expected to be transported to permitted disposal areas. As each basin is completed, a hopper dredge can begin to remove sand from the borrow area and transport it to the basin where it can be quickly dumped, allowing the dredge to have minimal delays between trips. When the sand in a basin reaches a set capacity, a cutter head, suction dredge will move the sand from the basin to the area where the sand is needed. Where needed, booster pumps will be utilized. The discharge from the suction dredge will be moved over the areas where the size of the island is being increased. As an area is filled to the desired grade, the sand will be shaped into dunes, basins and beaches. As this earthwork is completed for a given area, planting can begin. The suction dredge will be moved as needed to accommodate the excavation of the basins and the transfer of the sand from the basins to the islands. It is anticipated that the suction dredge will be moved, and then remobilized several times during the entire process for completing an islands enlargement.

Option B and Option C propose to restore the islands by supplementing the sand in the littoral system through the use of inland and off-shore sand sources. This could be accomplished by adding sand in specific locations based on sediment transport modeling. This would allow the littoral currents to move the sand onto the islands where the natural process of island building could take place. This would not directly affect the present-day islands and would help mitigate any effects of dredging the ship channels that pass through the chain of islands where sand may have been lost from the system. The construction of inland waterways in Alabama and Mississippi has resulted in continuing maintenance dredging to maintain the channel depths and alignments. This dredged material is now accumulated in disposal areas along the banks of the river. Dredging of some of the areas along the river has produced large quantities of sand that have potential use for replenishment of littoral zones such as are found along the Mississippi Barrier Islands. An inventory of current disposal sites indicates that approximately 30,000,000 cubic yards of sand is available. Only disposal sites that contain a minimum of 100,000 cubic yards of sand were included in the inventory. Of interest to this study are disposal sites that are located along the Black Warrior – Tombigbee River system and the Tennessee – Tombigbee Waterway. Material from these sites could easily be transported by barge down the river system for use among the islands littoral zone. To add off-site sand into the littoral system under Option B, material from inland dredged material disposal sites would be transported by barge down the river system for use among the islands littoral zones.

Each of the areas designated for adding sand will require that a staging area where barges could be unloaded and the sand spread over the selected area. The sand would be transported from each of numerous disposal sites located up the river systems. The size of the locks on the river systems and the depth of associated channels will dictate the size of barges that can be used. As the barges are unloaded at each site, the sand would be pumped to spreader barges that would be able to cover an area sufficient to control the depth of sand placement.

Option C would help restore the islands by supplementing the sand in select littoral system zones with sand obtained from both inland river and offshore borrow areas. Like Option B, this could be accomplished by adding sand in specific locations based on sediment transport modeling. This option would limit addition of sand to the areas east of Ship Island and Petit Bois Island. These two areas were selected based on cooperation between the National Park Service (NPS, 2007) and the Corps of Engineers and is based on restoration policy of natural resources with the NPS. Both of these islands are affected by the presence of navigation channels that limit westward migration. Placement of sand into these two areas would add sediment into the system and would allow the littoral currents to move the sand onto the islands where the natural process of island building could take place. The sand that could be used in this option may come from the same offshore borrow area as Option A, the St. Bernard Shoals located about 45 miles south of the barrier islands and the lower inland river sand described in Option B. The sand from the inland river sources would be from the lower-most areas.

Options D and E involve environmental restoration of the islands consisting of shaping existing sand into dunes on the beaches with planted vegetation and planting of maritime forests on the existing islands where they were mostly destroyed by Hurricane Katrina. For Option D the dune would be shaped from sand that would be removed from the surface between the constructed dune and the edge of the vegetation north of the dune. The dune would have height of 2-feet with a 1v to 3h slopes and a crest width of 6 feet. The dune would be continuous for the length of the gulf-side, south beach. While not designed as a structural defense against storms, the dune would be used as a platform to establish a line of sea oats that in turn would help in the natural process of creating larger and more pronounced sand dunes. The dunes would build with time as wind driven deposits of sand become trapped by the vegetation. For Option E, the dune would have height of 6-feet with a 1v to 3h slopes and a crest width of 6 feet. The sand required to construct a dune of this size would be more than could be removed from the existing beach berm and would come from the same offshore borrow area as the sand used in Option A. Placement of the sand would require moving the sand from a hopper dredge to a staging area on the beach, then moving the sand to the area of placement along the beach.

Option F involves environmental restoration of the sea grass beds that have historically existed on the north side of the islands in the Mississippi Sound. Despite continual changes that occur, the barrier islands remain to buffer the mainland from storms and provide habitat for the rich, diverse wildlife residing within the area. The amount of acres of sea grasses to be planted at each island, based on 50 percent of pre-Camille acreage, is as follows: Cat – 210 acres, Ship – 760 acres, Horn – 2,650 acres, and Petit Bois – 780 acres. This option will involve only the planting of various types of marine aquatic vegetation in selected areas around the islands. No actual construction activities will take place.

Option G proposes to the fill the Ship Island breach. The pre-Camille footprint of Ship Island was obtained from historical records, and showed the area that was breached during Hurricane Camille forming two separate islands. West and East Ship Island has two major historic sites that are in danger from the continuing erosion of the barrier islands. Current studies by the Corps indicate that restoring the two islands to a single island, pre-Camille condition may prevent the rapid erosion of the beaches that is now occurring as well as helping to provide wave erosion on the mainland. Estimates indicated that the restoration of Ship Island to a single land mass off the Mississippi coast will involve approximately 21 million cubic yards of sand. Fort Massachusetts was originally built on the western tip of Ship Island. The westward migration of sand along the southern shore and erosion of the northern shore now has put the fort almost a mile from the western tip of the island, but dangerously close to being in the Sound. Several emergency beach re-nourishments have taken place over the last 35 years through use of operations and maintenance material from the federally authorized Gulfport Harbor Navigation Project to protect the fort from wave action during winter

storms. At present, the NPS is again requesting that the Corps place sand along the shore near the fort in conjunction with dredging operations at the Federal Gulfport Harbor navigation channel. This emergency placement of sand is being repeated about every five to six years. The immediate erosion problem will require re-nourishment of the beach adjacent to the fort similar to the past protection projects. The problem of a long-term fix may be tied to closing the three mile wide breach known as Camille Pass between West and East Ship Island. As well as the sand placement, the plan would include sculpting the sand into beaches, dunes, swales, and marshes. Different types of vegetation planting would also be included to restore habitat on the newly created land. The filling of Camille Pass will also provide a designation of a Federal Beach that would be subject to long term maintenance if needed.

Review of literature indicates that suitable sand can be obtained from St. Bernard Shoals which is located about 45 miles south of Ship Island. This sand should be very high quality material and could be used in the island reconstruction. If this offshore sand source is used, a basin would be dredged near each of the islands to discharge the sand being transported from the borrow area. Using this procedure, the hopper dredge could enter the basin and bottom dump the sand. This would be much faster than pumping off the sand. Doing this would also allow the basin to be placed outside the boundaries of the National Seashore. As the basin is filled, a suction dredge would be mobilized to the site and using this type of the equipment, the sand could be moved to the area where the material is needed to create additional land mass. As the sand is placed on the new land mass, it would be sculpted into dunes and swales which would vary from sea level up to heights of 20 feet.

Another source of sand could be sand from inland river systems as discussed in Option B. Material from these sites could easily be transported by barge down the river system for use as replacement sand in the littoral system of the barrier islands. The offshore sand source and the sand from the inland river systems sites provide sufficient sand for the project construction. The anticipated amount of sand required for each island is as follows:

Cat Island – 14,600,000 cubic yards

Ship Island – 21,240,000 cubic yards

Horn Island – 21,240,000 cubic yards

Petit Bois Island – 9,300,000 cubic yards

3.1.2 Real Estate Requirements

Real Estate requirements for Line of Defense 1 will include a Permit from DOI/NPS to allow for beach re-nourishment, dune construction and plantings to include submerged aquatic vegetation. It will also be necessary to obtain a license from the Minerals Management Agency for mining of sand from those offshore borrow areas in the outer continental shelf, and also to create the “dump basins” needed at each island during construction. It is noted that the Engineering Appendix suggests the use of “permitted disposal areas” for borrow and disposal activity. An assumption is made that some type of permit will be required for borrow/disposal of materials in these areas. This will be investigated further in the next phase, Pre-Construction, Engineering and Design.

3.1.3 Utility/Facility Relocation

There are no utility or facility relocations in any of the options for the offshore barrier islands.

3.1.4 Existing Projects/Studies

Several emergency beach re-nourishments have taken place over the last 35 years on Ship Island to protect Fort Massachusetts from wave action during winter storms. This emergency placement of sand is being repeated about every five to six years. Sand has come from dredging of the federally authorized Gulfport Harbor Navigation Project. Other relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.1.5 Environmental Impacts

None of the options described for the offshore barrier islands are expected to cause negative impacts to the surrounding environment. See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.1.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Since the project will be constructed on lands in the Outer Continental Shelf, any new lands created as a result of the project will be considered lands of the United States of America. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.1.7 Government Owned Property

All of Petit Bois, Horn, and Ship Islands and the western two thirds of Cat Island are within the boundaries of the Gulf Islands National Seashore under jurisdiction of the NPS. In most cases, the boundary extends one mile from the shore of the island. The remaining portion of Cat Island is in private ownership held among multiple owners of record.

3.1.8 Historical Significance

The breach of Ship Island has created problems for the National Park Service due to the location of two historically important sites. Fort Massachusetts is located on the northern shore of West Ship and the French Warehouse is located on the northern shore of East Ship Island. Both of these sites are endangered by on-going erosion of the shoreline with Mississippi Sound. Another site, known as the Quarantine Station, has already been lost to erosion. These sites are shown in Figure 3.1.8-1. See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

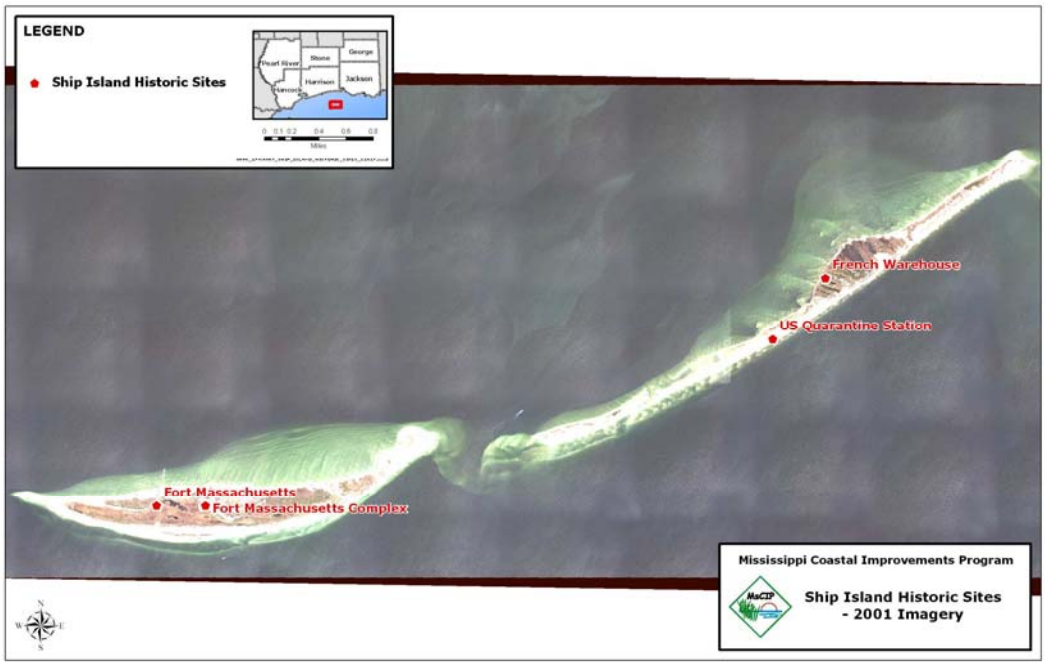

Figure 3.1.8-1. Aerial photo of West and East Ship Island taken in 2001 showing historic sites

3.1.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.1.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the islands and lack of prior development, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.1.11 Public Law 91-646, Relocation Assistance Benefits

Not Applicable

3.1.12 Attitude of Property Owners

There are no known objections to the proposed project.

3.1.13 Acquisition Schedule

All permits must be obtained prior to advertisement for construction. This could be accomplished in 90 - 120 days. An acquisition schedule will be made during PED and will be a joint effort of the NFS, the project manager and Real Estate.

3.1.14 Estates for Proposed Project

No estates are required for the project. All work will be done by permit from the appropriate agency.

3.1.15 Real Estate Estimate

The real estate cost estimate at Table 3.1.15-1 includes a cost for Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. With the exception of a portion of Cat Island that is privately owned, the project will be constructed on offshore barrier islands owned by the Federal Government, so no additional land costs are anticipated. That portion of Cat Island that is privately owned will not be impacted by the project. No cost is included for upland borrow sites as sites have been identified where it will be advantageous to remove fill to make room for future disposal. All costs are for obtaining permits. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estate. Due to the ownership of the islands, the same administrative cost is projected for any individual option or combinations of options.

Table 3.1.15-1.
Offshore Barrier Islands Estimate

a. Lands and Improvements/Permits				0
			Subtotal	0
b. Mineral Rights				0
c. Damages				0

e. Administrative Cost				15,000
	Relocation	Acquisition	Total	
Federal	0	7,500	7,500	
Non-Federal	0	7,500	7,500	
	0	15,000	15,000	
Subtotal				15,000
Contingencies (25%)				3,750

	Totals	**18,750**
	Rounded	**19,000**

3.1.16 Summary of Potential Real Estate Issues

The requirement for using borrow material from the "permitted" sites will be further investigated during PED. Typically if borrow sites are required, this would be considered as part of the LERRD requirements. Real estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should an upland borrow site become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with an upland site and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared and provided to CESAD-PDS-R for review and approval.

Requirements for long term O&M and any associated real estate interests will be identified during PED.

3.1.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.1.17-1 shows the CWBS for real estate activities.

Table 3.1.17-1.

3.2 Line of Defense 2 - Beach/Dune Construction

The Mississippi Mainland shoreline extends approximately 68 miles, and is divided into three coastal counties: Jackson, Harrison, and Hancock Counties, Figure 3.2-1. The Mississippi coast beaches are a valuable asset and provide vital environmental, cultural, recreational, and economic resources; they assist in maintaining the health and productivity of adjacent waters and provide for diverse cultural and recreational activities.

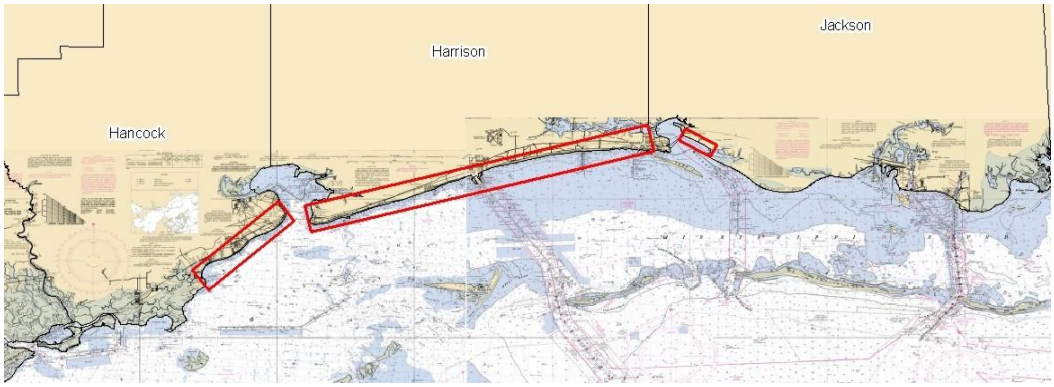

Figure 3.2-1. Mississippi Beaches

Essentially all the beaches along coastal Mississippi are man-made. Harrison County has the most beach-front with 26-miles extending from Biloxi Bay to St. Louis Bay. Hancock County has several miles of beach and Jackson County only a short length. In total, the beaches extend along less than half of the Mississippi coastline. Most of the dunes that previously existed along these beaches were destroyed by Katrina and much of the beach was damaged. Reconstruction of the dunes, where beaches exist, will provide reduction of damaging wave action from smaller storms. A project to restore the beaches in Harrison County has been funded and is underway. Other projects to construct dunes to a height of 5-feet in Harrison County and to 2-feet in Hancock and Jackson County have been proposed as an interim projects, have been designed and are awaiting funding.

Dunes are consistent with a more natural appearing defense than a hard structure. Construction of dunes will include adding vegetation and sand fencing to help stabilize the dunes. The dunes would be a sacrificial barrier, but could also be important by providing additional protection for the toe of the existing roadway, especially in an elevated seawall or roadway configuration as LOD-3. Placement of the dunes directly against a raised seawall or roadway would also serve aesthetically to mask the appearance of a structural barrier.

3.2.1 Hancock County Beaches

3.2.1.1 Project Description

The purpose of this project is to provide hurricane storm damage reduction and restoration of the shoreline to six miles of public beaches along the Hancock County, MS coastline which was impacted by tidal flooding during Hurricane Katrina in August 2005.

Hancock County is the western-most coastal county in Mississippi and is located approximately 95 miles west of Mobile, Alabama and approximately 40-miles east of New Orleans, Louisiana. Hancock County is bordered to the east by Harrison County, MS, and to the west by the Mississippi-

Louisiana state line. The County consists of two municipalities: Bay St. Louis and Waveland. The beaches along the Hancock County shoreline, shown in Figure 3.2.1.1-1, are separated in two sections: the reach extending approximately 6-miles from Grand Bayou in Waveland to the US 90 bridge in Bay St Louis, and the reach extending northeastward approximately 1-mile from Cadet Bayou.

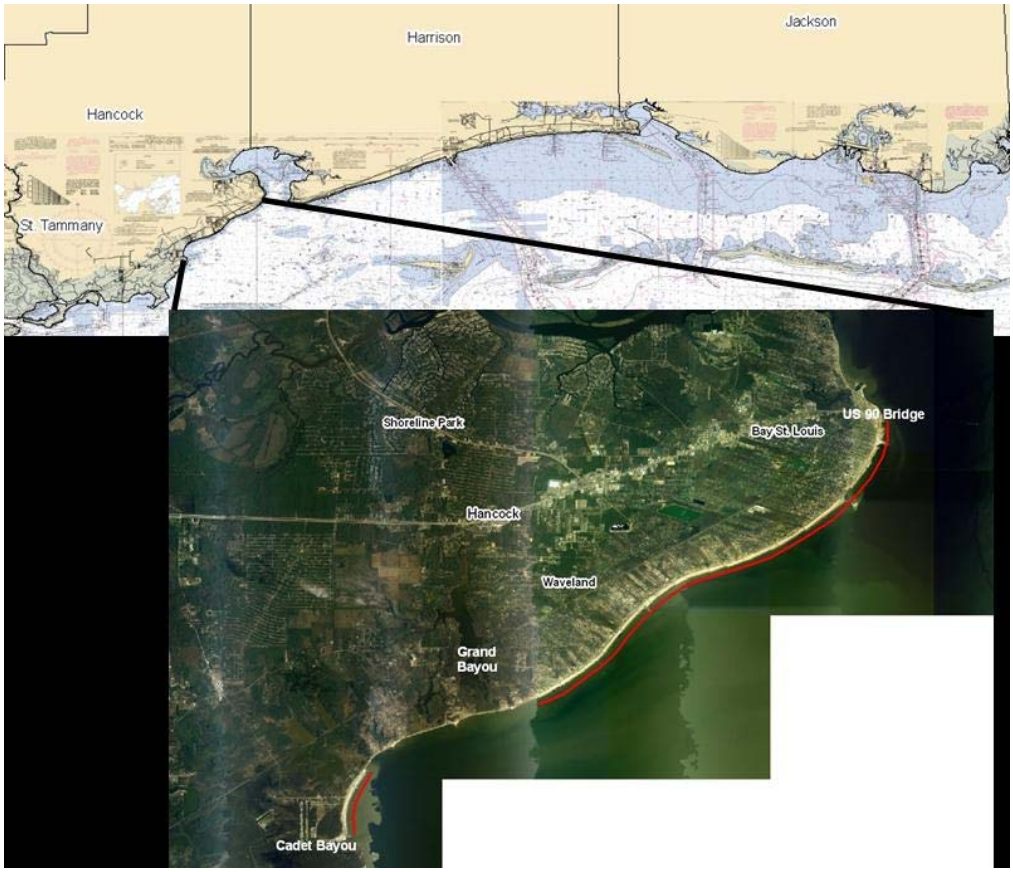

Figure 3.2.1.1-1. Hancock County Beaches

The Hancock County shoreline south of the US 90 bridge is protected by an 8 mile long seawall extending from the US 90 bridge to Cadet Bayou. The Hancock County beaches were constructed for shore protection; however, the area provides added outdoor recreation and environmental benefits. The project was a local project constructed by Hancock County. The area experiences wave and wind erosion and is therefore periodically maintained or re-nourished with sand. The elevation of the seawall ranges between +3.8 and +5.0 feet National Geodetic Vertical Datum (NGVD). The seawall fronting the downtown Bay St Louis beaches is significantly higher. A sand beach was constructed along approximately 6 miles of the seawall in 1967 as part of the emergency repair and protection following Hurricane Betsy (September 1965). The approximately 1 mile section of beach fronting the downtown Bay St Louis area was constructed during the construction of the US 90 Bridge. The 1 mile section extending from Bayou Cadet was constructed in 2005.

The Hancock County beaches were re-nourished in 1994 with material from a borrow area located approximately 1000 feet offshore. The beaches fronting downtown Bay St Louis, the northeast section of the beaches, were again re-nourished in 1996 with material from a borrow area located on the north side of the US 90 bridge. The existing Hancock County beach profile consists of a berm only feature which extends approximately 150 ft from the seawall to the Mississippi Sound. The berm elevation varies from approximately 5.0 ft at the seawall to 3.5 ft at the slope break to the Mississippi Sound. The downtown Bay St Louis area beaches include a bluff with an elevation of about +12 feet.

The project includes evaluation of eleven options in Hancock County as listed in Table 3.2.1.1-1.

Table 3.2.1.1-1.
Hancock County LOD2 Options

Option	Description					
	Dune			Berm		
	Elevation (ft)	Width (ft)	Side Slope	Width (ft)	Plantings	Sand Fencing
A*	10	40	1:3	80		
B*	8	50	1:3	80		
C*	10	20	1:3	100		
D*	8	30	1:3	80		
E*	10	40	1:3	80	X	X
F*	8	50	1:3	80	X	X
G*	10	20	1:3	100	X	X
H*	8	30	1:3	100	X	X
I**	10	55	1:3	Extend to accommodate		X
J**	10	55	1:3	Extend to accommodate	X	X
K**				Add 2ft, 60 ft width	X	X

* Options are in conjunction with the LOD3 Seawall

** Options are without a seawall

The future with-project evaluations for Hancock County included 11 options which were evaluated for environmental restoration and enhancement of environmental habitat and hurricane storm damage reduction. Options A through D include four design cross-sections with varying dune and berm configurations. The berm and dune options would be constructed adjacent to the seawall along the length of the beach. For environmental and economic purposes, Options E through H further evaluated the four design cross-sections to include sand fencing and plantings on the dune to provide environmental habitat and to reduce sand transport due to the strong winds, which frequently occur during storms. The wider dune features would provide for a larger spatial extent with which to create environmental habitat. Options A through H were evaluated in conjunction with the Line of Defense 3 seawall. Typical cross sections for Options A through D are shown in Figure 3.2.1.1-2. The same cross sections were used for Options E through H. For Options E through H, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.

Options I and J are comparative with-project options, for future evaluation, consisting of a design cross-section which includes a dune and berm constructed as a stand alone project which does not incorporate the Line of Defense 3 seawall. Option I consists of a dune feature constructed approximately 50 ft seaward of the seawall. The berm width would be extended to accommodate the placement of the dune feature. Sand fencing would be placed on the dunes to reduce sand transport due to the strong winds which frequently occur during storms. The cross section for Option J is the

same as Option I; however the dune would be planted to provide for additional environmental habitat. For Option J, sea oats would be planted on both the landward and seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the landward and seaward toes of the dune. The dunes will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Options I and J is shown in Figure 3.2.1.1-3.

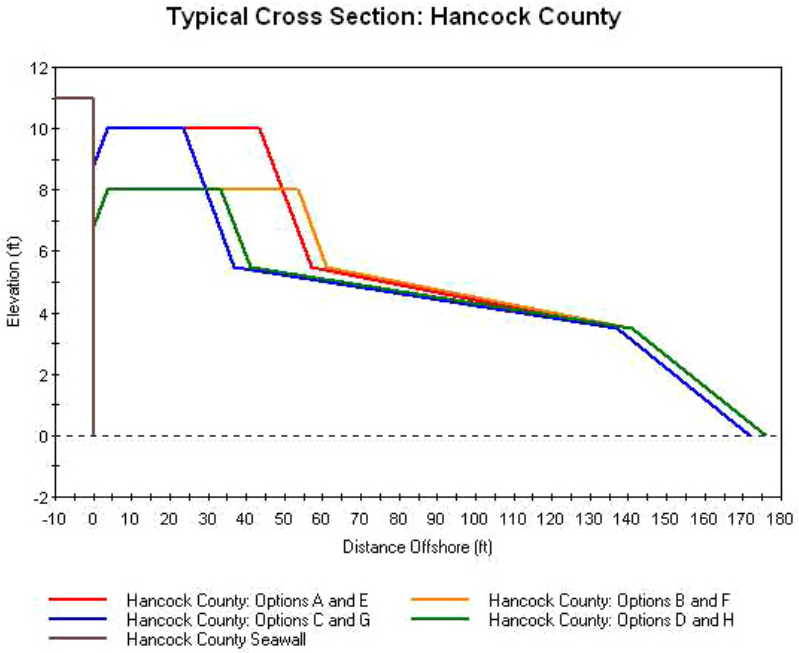

Figure 3.2.1.1-2. Typical Cross Sections, Hancock County Options A-D and E-H

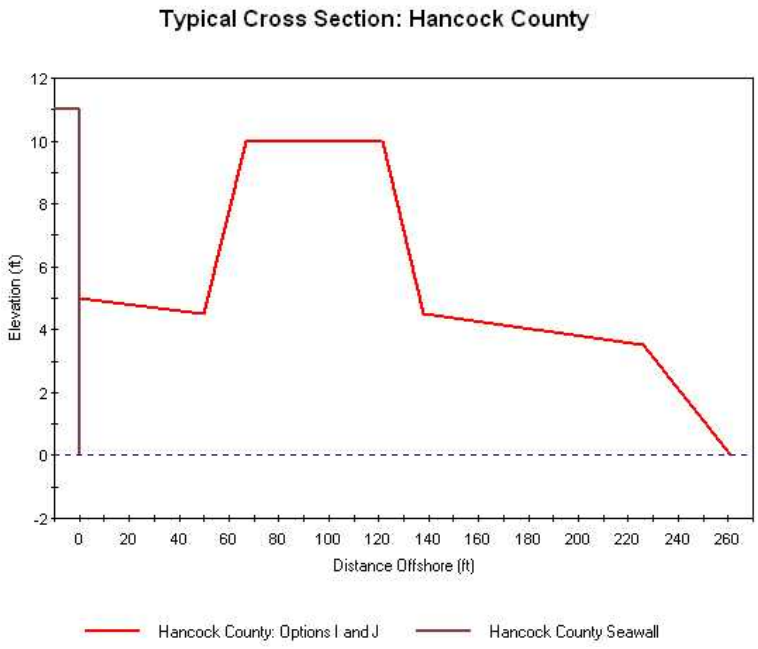

Figure 3.2.1.1-3. Typical Cross Section, Hancock County Comparative Dune Options I and J

Option K is also an option for future evaluation which consists of an elevated berm section constructed primarily for the creation of environmental habitat. Option K would be constructed as a stand alone option which does not incorporate the Line of Defense 3 seawall. The elevated berm section would be constructed approximately 50 ft seaward of the existing seawall to an elevation 2 ft above the existing berm with a width of approximately 60 ft. The berm width would not be extended to accommodate the placement of the elevated berm feature. The new feature would be vegetated and sand fencing would be placed to create environmental habitat and to reduce sand transport due to the strong winds which frequently occur during storms. For Option K, sea oats would be planted in a 30 by 30 inch grid pattern over the entire elevated berm area. The new feature will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Option K is shown in Figure 3.2.1.1-4.

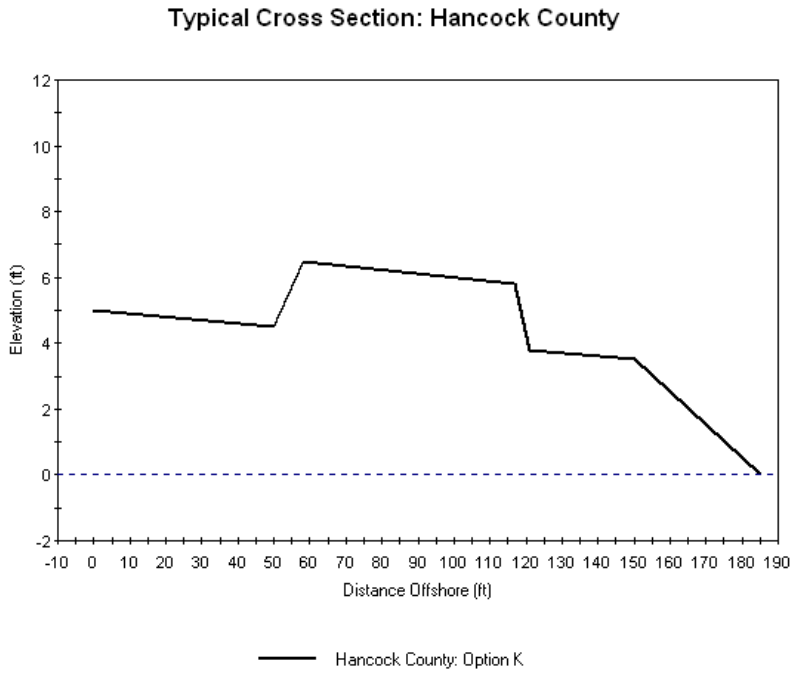

Figure 3.2.1.1-4. Typical Cross Section, Hancock County Option K

3.2.1.2 Real Estate Requirements

Real Estate requirements for Line of Defense 2 for Hancock County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), the right to construct a dune atop the existing beach along with a fence and dune vegetation. Hancock County Tax Maps show parcels under private ownership that are seaward of Beach Boulevard and the seawall. However, under statutory authority, the State claims ownership of all lands seaward of the seawall, and an assumption is made that no further easements will be needed on those lands. An assumption is made that a real estate interest would have been obtained to allow for the original construction of the beaches and subsequent re-nourishment activity. This will be confirmed upon further analysis during PED.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the dune. See Section 2.8 Borrow Areas on page 5. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. Access to the project will be along public roadways and staging is expected to be on sponsor owned lands if required. Addendum C of the Economics Appendix discusses the availability of public parking and access for all three counties. No public access issues have been identified. However, if additional public beach access or parking is required, the sponsor will be responsible for acquiring those real estate interests. Acquisition of additional interests for access and parking are considered as requirements for participation in a Federal project and are not considered as creditable items toward project cost.

3.2.1.3 Utility/Facility Relocation

Some temporary rework of the storm drainage system may be necessary during construction of the project. See Chapter 2 Section 2.10 for more detailed discussion.

3.2.1.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.2.1.5 Environmental Impacts

None of the options described for LOD2 are expected to cause negative impacts to the surrounding environment. See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.2.1.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.2.1.7 Government Owned Property

There are no known Government owned lands within the proposed project.

3.2.1.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.2.1.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.2.1.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.2.1.11 Public Law 91-646, Relocation Assistance Benefits

Not Applicable.

3.2.1.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.2.1.13 Acquisition Schedule

An assumption is made that the sponsor holds an interest in all lands required for the project. Certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. This can be accomplished within 30 days. However, if a borrow area or temporary work area easements become a requirement, 6-12 months should be allowed for easement acquisition of the sites. An acquisition schedule will be made during PED and will be a joint effort of the NFS, the project manager and Real Estate.

3.2.1.14 Estates for Proposed Project

An assumption is made that no easements will be required on lands seaward of the seawall. Should a borrow site be required, the Borrow Easement should be used. The Temporary Work Area Easement will be used for any staging or temporary work areas if required. The estates recommended are standard estates.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____,

beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.2.1.15 Real Estate Estimate

The real estate cost estimate at Table 3.2.1.15-1 includes a cost for Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. The State claims ownership of those lands seaward of the seawall, so no additional land costs are anticipated. No cost is included for an upland borrow site. The requirement, if any, for an upland borrow site will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate. The same administrative cost is projected for any individual option or combinations of options.

Table 3.2.1.15-1.
LOD2 Hancock County Estimate

a. Lands and Improvements/Permits					0
				Subtotal	0
b. Mineral Rights					0
c. Damages					0
d. P.L. 91-646 Relocation costs					0
e. Administrative Cost					15,000
		Relocation	Acquisition	Total	
	Federal	0	7,500	7,500	
	Non-Federal	0	7,500	7,500	
		0	15,000	15,000	
Subtotal					15,000
Contingencies (25%)					3,750
	Totals				**18,750**
	Rounded				**19,000**

3.2.1.16 Summary of Potential Real Estate Issues

The requirement for borrow areas or temporary work areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should borrow areas or temporary work areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Specific requirements for long term O&M and any associated real estate interests will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

3.2.1.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.2.1.17-1 shows the CWBS for real estate activities.

3.2.2 Harrison County Beaches

3.2.2.1 Project Description

The purpose of this project is to provide hurricane storm damage reduction and restoration of the shoreline to 26 miles of public beaches along Harrison County, MS coastline which was impacted by tidal flooding during Hurricane Katrina in August 2005.

The Mississippi mainland shoreline is divided into three coastal counties: Jackson, Harrison, and Hancock Counties. Harrison County, extends approximately 26-miles, has the largest population, and the greatest number of municipalities. It is bordered on the east by industrialized Jackson County, on the west by Hancock County and the John C. Stennis Space Center and to the north by primarily rural Stone County. The County consists of five municipalities: Biloxi, D'Iberville, Gulfport, Long Beach, and Pass Christian. The Harrison County Federal Shore Protection Project shown in Figure 3.2.2.1-1 extends approximately 26-miles from Biloxi on the east to Henderson Point on the west.

As a result of the 1915 hurricane which destroyed half of U.S. 90, a seawall was constructed to protect the roadway and beach front property. After the hurricane in 1947 and due to ongoing loss of sediment, the Harrison County, Mississippi Federal Beach Erosion Control Project was constructed in 1952 under the Section 2 authority of the River and Harbor Act .The project was constructed to protect the seawall and US 90, which provides an evacuation route for residents. The non-federal sponsor was Harrison County.

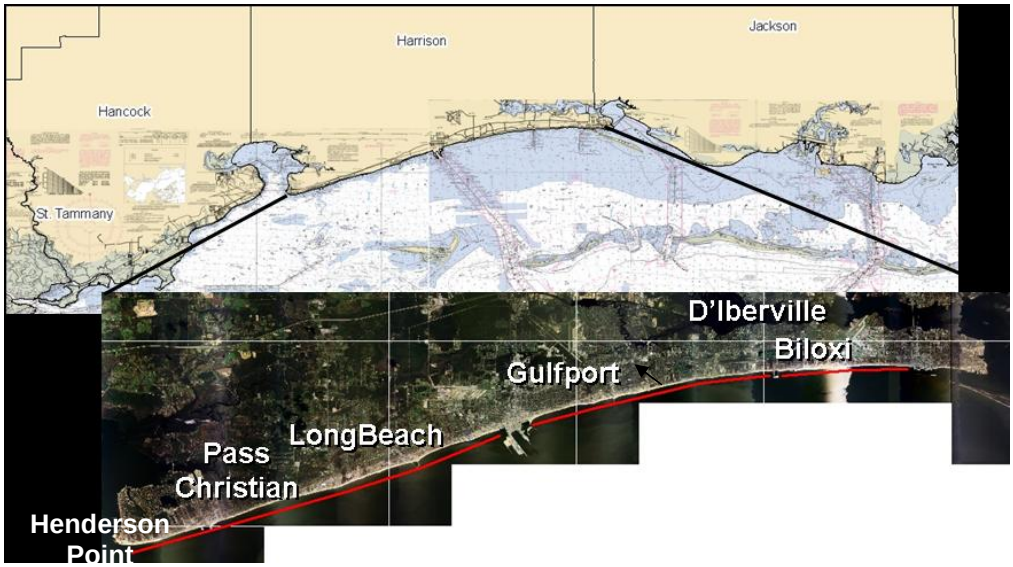

Figure 3.2.2.1-1. Project Location, Harrison County Beaches

The authorized Harrison County project provides for a beach profile consisting of a berm only feature which extends approximately 265 ft from the seawall to mean sea level (MSL). The berm elevation varies from an elevation of approximately 7.2 ft (NAVD 88) at the seawall to 3.5 ft at the slope break to the Mississippi Sound. Storm water culverts pass beneath US 90 to the shoreline to drain sections of Biloxi, Long Beach, and Pass Christian. The Harrison County beaches were last re-nourished in 2001, which placed approximately 1.1 million CY of beach quality sand obtained from borrows sites located about 1,500 ft offshore of the Harrison County shoreline. During Hurricane Katrina on 29 August 2005, the project experienced erosional damage due to wind driven waves, debris scour, storm surge and subsequent return flow after the hurricane.

The project includes the evaluation of eleven options in Harrison County as listed in Table 3.2.2.1-1.

Table 3.2.2.1-1.
Harrison County LOD2 Options

Option	Description					
	Dune			Berm		
	Elevation (ft)	Width (ft)	Side Slope	Width (ft)	Plantings	Sand Fencing
A*	15	35	1:3	160		
B*	13	45	1:3	160		
C*	15	25	1:3	170		
D*	13	15	1:3	160		
E*	15	35	1:3	160	X	X
F*	13	45	1:3	80	X	X
G*	15	25	1:3	170	X	X
H*	13	15	1:3	160	X	X
I**	15	55	1:3	Extend to accommodate		X
J**	15	55	1:3	Extend to accommodate	X	X
K**				Add 2ft, 60 ft width	X	X

* Options are in conjunction with the LOD3 Seawall

** Options are without a seawall

The future with-project evaluations for Harrison County included 11 options which were evaluated for environmental restoration and enhancement of environmental habitat and for hurricane and storm damage reduction. Options A through D included four design cross-sections with varying dune and berm configurations. The berm and dune options would be constructed adjacent to the seawall along the length of the beach. For environmental and economic purposes, Options E through H further evaluated the four design cross-sections to include sand fencing and plantings on the dune to provide environmental habitat and to reduce sand transport due to the strong winds, which frequently occur during storms. The wider dune features would provide for a larger spatial extent with which to create environmental habitat. Options A through H were evaluated in conjunction with the Line of Defense 3 seawall. The dunes will be constructed to accommodate the approximately 10 ft wide boardwalk which extends along most of the Harrison County seawall. Typical cross sections for Options A through D are shown in Figure 3.2.2.1-2. The same cross sections were used for Options E through H. For Options E through H, sea oats would be planted on the seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the seaward toe of the dune.

Options I and J are comparative with-project options, for future evaluation, consisting of a design cross-section which includes a dune and berm constructed as a stand alone project which does not incorporate the Line of Defense 3 seawall. Option I consists of a dune feature constructed approximately 50 ft seaward of the seawall at an elevation of 15 ft (NAVD 88), with a crest width of 55 ft, and a dune slope of 1:3. The berm width would be extended to accommodate the placement of the dune feature. Sand fencing would be placed on the dunes to reduce sand transport due to the strong winds which frequently occur during storms. The cross section for Option J is the same as Option I; however the dune would be planted to provide for additional environmental habitat. For Option J, sea oats would be planted on both the landward and seaward dune face in an 18 by 18 inch grid pattern, with a total of three rows of plants starting at the landward and seaward toes of the dune. The dunes will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Options I and J is shown in Figure 3.2.2.1-3.

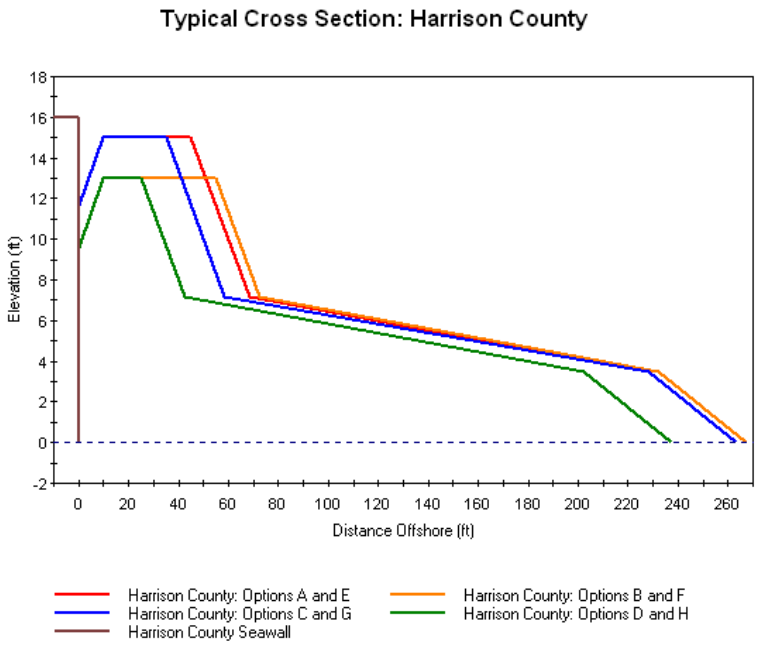

Figure 3.2.2.1-2. Typical Cross Sections, Harrison County Options A-D and E-H

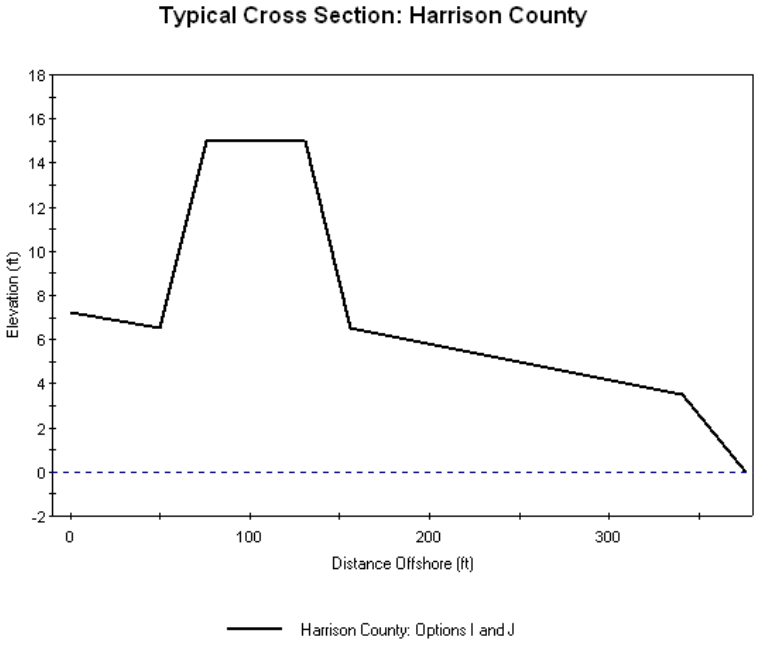

Figure 3.2.3.1-3. Typical Cross Section, Harrison County Comparative Dune Options I and J

Option K is also an option for future evaluation which consists of an elevated berm section constructed primarily for the creation of environmental habitat. Option K would be constructed as a stand alone option which does not incorporate the Line of Defense 3 seawall. The elevated berm section would be constructed approximately 50 ft seaward of the existing seawall to an elevation 2 ft above the existing berm with a width of approximately 60 ft. The berm width would not be extended to accommodate the placement of the elevated berm feature. The new feature would be vegetated and sand fencing would be placed to create environmental habitat and to reduce sand transport due to the strong winds which frequently occur during storms. For Option K, sea oats would be planted in a 30 by 30 inch grid pattern over the entire elevated berm area. The new feature will require initial and continued maintenance of vegetation and sand fencing. A typical cross section for Option K is shown in Figure 3.2.2.1-4.

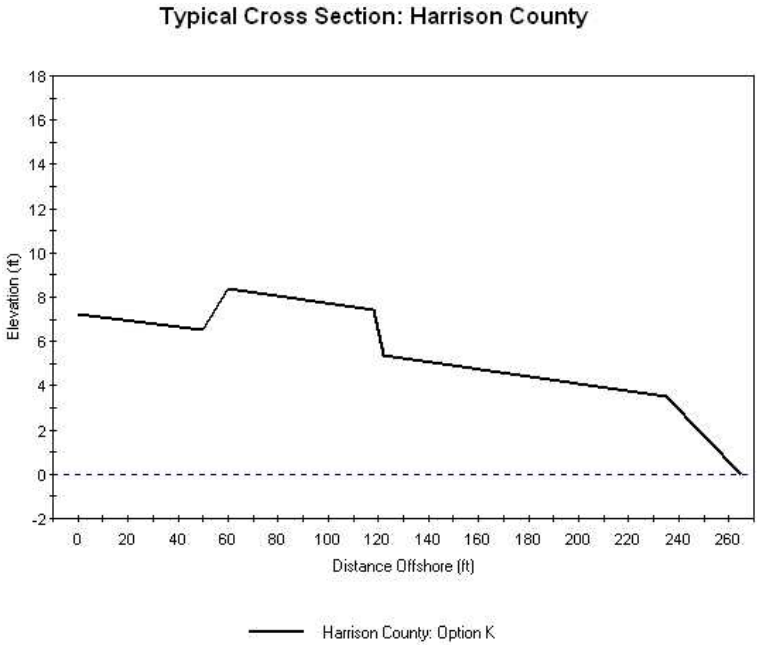

Figure 3.2.2.1-4. Typical Cross Section, Harrison County Option K

3.2.2.2 Real Estate Requirements

Real Estate requirements for Line of Defense 2 for Harrison County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), the right to construct a dune atop the existing beach along with a fence and dune vegetation. Harrison County Tax Maps show parcels under private ownership that are seaward of Beach Boulevard and the seawall. However, the State claims ownership of all lands seaward of the seawall, and an assumption is made that no further easements will be needed on those lands. An assumption is made that a real estate interest would have been obtained to allow for the original construction of the beaches and subsequent re-nourishment activity. This will be confirmed upon further analysis during PED. The sand used for project construction is expected to come from established off shore sources within one mile of the work area. Appropriate permitting will be required to borrow from the off shore sites.

Access to the project will be along public roadways and staging is expected to be on sponsor owned lands if required. Addendum C of the Economics Appendix discusses the availability of public parking and access for all three counties. No public access issues have been identified. However, if additional public beach access or parking is required, the sponsor will be responsible for acquiring those real estate interests. Acquisition of additional interests for access and parking are considered as requirements for participation in a Federal project and are not considered as creditable items toward project cost.

3.2.2.3 Utility/Facility Relocation

There are no known utility or facility relocations in any of the options for the berm and dune construction.

3.2.2.4 Existing Projects/Studies

The Harrison County Shore Protection Project was completed in June 1952 and provided for the repair of the existing 24 mile long Harrison County seawall and its protection by the construction of a beach from Biloxi Lighthouse to Henderson point near Pass Christian. The beach has been maintained by Harrison County since then. During PED a determination will be made of what interest was acquired for the project. Other relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.2.2.5 Environmental Impacts

None of the options described for LOD2 are expected to cause negative impacts to the surrounding environment. See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.2.2.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the

non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.2.2.7 Government Owned Property

There are no known Government owned lands within the proposed project.

3.2.2.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.2.2.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.2.2.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.2.2.11 Public Law 91-646, Relocation Assistance Benefits

Not Applicable

3.2.2.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.2.2.13 Acquisition Schedule

An assumption is made that the sponsor holds an interest in all lands required for the project. Certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. This can be accomplished within 30 days. However, if temporary work area easements become a requirement, 6-12 months should be allowed for an easement acquisition of the sites. An acquisition schedule will be made during PED and will be a joint effort of the NFS, the project manager and Real Estate.

3.2.2.14 Estates for Proposed Project

An assumption is made that no easements will be required on lands seaward of the seawall. The standard estate Temporary Work Area Easement will be used for any staging or temporary work areas if required.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.2.2.15 Real Estate Estimate

The real estate cost estimate at Table 3.2.2.15-1 includes a cost for Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. The State claims ownership of those lands seaward of the seawall, so no additional land costs are anticipated. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate. The same administrative cost is projected for any individual option or combinations of options.

Table 3.2.2.15-1.
LOD2 Harrison County Estimate

a. Lands and Improvements/Permits					0
				Subtotal	0
b. Mineral Rights					0
c. Damages					0
d. P.L. 91-646 Relocation costs					0
e. Administrative Cost					15,000
		Relocation	Acquisition	Total

	Non-Federal	0	7,500	7,500	
		0	15,000	15,000	
Subtotal					15,000
Contingencies (25%)					3,750
	Totals				**18,750**
	Rounded				**19,000**

3.2.2.16 Summary of Potential Real Estate Issues

If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Should temporary work areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Specific requirements for long term O&M and any associated real estate interests will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

3.2.2.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.2.2.17-1 shows the CWBS for real estate activities.

3.2.3 Jackson County Beaches

3.2.3.1 Project Description

The purpose of this project is to provide hurricane storm damage reduction and restoration of the shoreline to 7 miles of public beaches along the Jackson County, MS coastline which was impacted by tidal flooding during Hurricane Katrina in August 2005.

The Mississippi mainland shoreline is divided into three coastal counties: Jackson, Harrison, and Hancock Counties. Jackson County is the eastern-most coastal county in Mississippi and is bordered on the east by the Mississippi-Alabama state line and on the west by Harrison County. Jackson County consists of four municipalities: Pascagoula, Moss Point, Gautier, and Ocean Springs. The beaches along the Ocean Springs shoreline are divided into two reaches: Front Beach extending approximately 1 mile southeastward from US 90 along Front Beach drive to the Ocean Springs Harbor, and East Beach extending approximately 1 mile from the Ocean Springs Harbor to Halstead Road, Figure 3.2.3.1-1.

Seawalls were constructed along the shoreline fronting the developed sections of Ocean Springs in the late 1920s. Two decades later, beach nourishment projects created sand beaches in front of two seawall segments, and the modern shoreline reaches of Front Beach and East Beach became named. Front Beach, more exposed to wave and tidal forces, experienced greater levels of erosion, and re-nourishment with dredged material was conducted in the 1970s. At wave-sheltered East Beach, marsh vegetation colonized the beachfront intertidal zone and thus assisted in the stabilization of the shoreline. Both Front Beach and East Beach systems only consist of a berm with landward elevations ranging from approximately 2.5 to 5 ft and berm widths of about 100 ft.

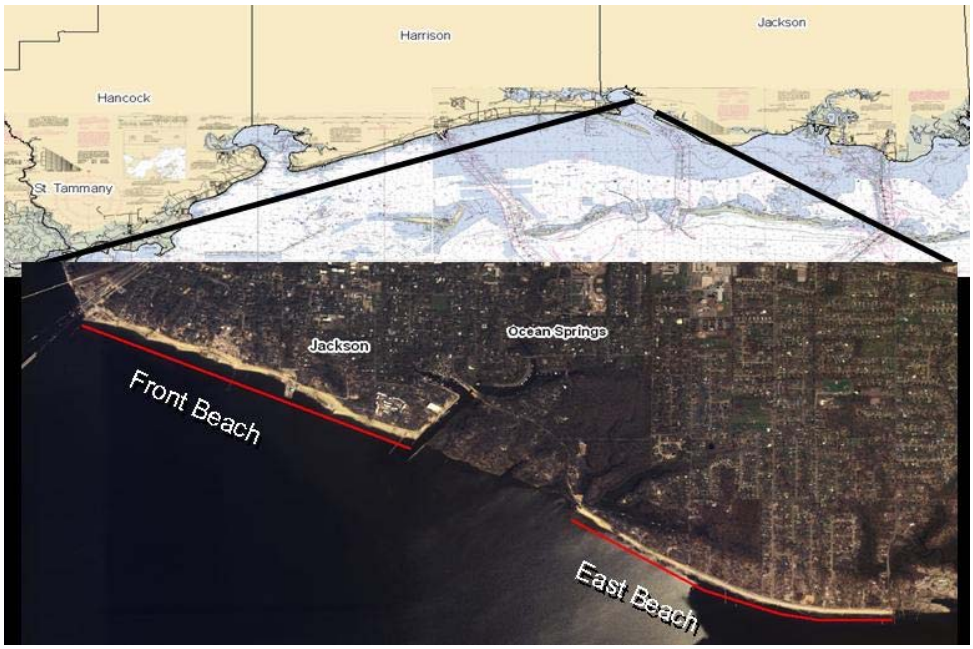

Figure 3.2.3.1-1. Project Location, Jackson County Beaches

The project includes evaluation of eleven options in Jackson County as listed in Table 3.2.3.1-1. Evaluation of the Jackson County beaches was based on the analysis of the Hancock County beaches. The Jackson County beach options are the same design as the Hancock County beaches; therefore the reader is referred to Section 3.2.1.1 for information regarding the Hancock County future with project options.

Table 3.2.3.1-1.

J**	10	55	1:3	Extend to accommodate	X	X
K**				Add 2ft, 60 ft width	X	X

* Options are in conjunction with the LOD3 Seawall

** Options are without a seawall

3.2.3.2 Real Estate Requirements

Real Estate requirements for Line of Defense 2 for Jackson County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), the right to construct a dune atop the existing beach along with a fence and dune vegetation. Jackson County Tax Maps show parcels under private ownership that are seaward of the beach boulevards. However, the State claims ownership of all lands seaward of the seawall, and an assumption is made that no further easements will be needed on those lands. An assumption is made that a real estate interest would have been obtained to allow for the original construction of the beaches and subsequent re-nourishment activity. This will be confirmed upon further analysis during PED.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the project. The sources are within ten miles of the work area. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. Access to the project will be along public roadways and staging is expected to be on sponsor owned lands if required. Addendum C of the Economics Appendix discusses the availability of public parking and access for all three counties. No public access issues have been identified. However, if additional public beach access or parking is required, the sponsor will be responsible for acquiring those real estate interests. Acquisition of additional interests for access and parking are considered as requirements for participation in a Federal project and are not considered as creditable items toward project cost.

3.2.3.3 Utility/Facility Relocation

There are no known utility or facility relocations in any of the options for the berm and dune construction.

3.2.3.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.2.3.5 Environmental Impacts

None of the options described for LOD2 are expected to cause negative impacts to the surrounding environment. See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.2.3.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.2.3.7 Government Owned Property

There are no known Government owned lands within the proposed project.

3.2.3.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.2.3.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.2.3.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.2.3.11 Public Law 91-646, Relocation Assistance Benefits

Not Applicable.

3.2.3.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.2.3.13 Acquisition Schedule

An assumption is made that the sponsor holds an interest in all lands required for the project. Certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. This can be accomplished within 30 days. However, if borrow or temporary work area easements become a requirement, 6-12 months should be allowed for an easement acquisition of the sites. An acquisition schedule will be made during PED and will be a joint effort of the NFS, the project manager and Real Estate.

3.2.3.14 Estates for Proposed Project

An assumption is made that no easements will be required on lands seaward of the seawall. Should a borrow site be required, the Borrow Easement should be used. The Temporary Work Area Easement will be used for any staging or temporary work areas if required. The estates recommended are standard estates.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.2.3.15 Real Estate Estimate

The real estate cost estimate at Table 3.2.3.15-1 includes a cost for Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. The State claims ownership of those lands seaward of the seawall, so no additional land costs are anticipated. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate. The same administrative cost is projected for any individual option or combinations of options.

Table 3.2.3.15-1.
LOD2 Jackson County Estimate

a. Lands and Improvements/Permits				0
			Subtotal	0
b. Mineral Rights				0
c. Damages				0
d. P.L. 91-646 Relocation costs				0
e. Administrative Cost				15,000
	Relocation	Acquisition	Total	
Federal	0	7,500	7,500	
Non-Federal	0	7,500	7,500	
	0	15,000	15,000	
Subtotal				15,000
Contingencies (25%)				3,750
	Totals			**18,750**
	Rounded			**19,000**

3.2.3.16 Summary of Potential Real Estate Issues

The requirement for borrow areas or temporary work areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should borrow areas or temporary work areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Specific requirements for long term O&M and any associated real estate interests will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

3.2.3.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.2.3.17-1 shows the CWBS for real estate activities.

3.3 Line of Defense 3 - Elevated Roadways, Seawall, and Ring Levees

All of the beaches described in the LOD-2 alternative have a roadway landward of the beach. The roads vary from local or county roads to US Highway 90, a major, four-lane highway that extends across the entire Harrison County coast. The existing roadways vary in elevation from four to five feet in Jackson and Hancock County and up to about 15 feet above sea level in Harrison County. All of these roads are evacuation routes and all have been damaged in past hurricanes. In a damaged or destroyed condition, these roads make re-entry to the area difficult after a hurricane has passed. Raising and using these roadways as barriers with an associated seawall defines a portion of the 3rd line of defense, LOD-3. This would be the first hard engineered structure that will not be affected by erosion from a storm such as a dune system.

Initial strategy was to study three elevations, 12.0, 18.0 and 24.0 feet. This coastal barrier will coincide with the beaches where they exist. Raising the beach-front road does present some engineering challenges due to the numerous intersections with other streets and roads. With any significant increase in elevation, the intersecting roads would require ramps that would be extremely long to have a reasonable grade. Each of these ramps would also create areas where rainfall would collect and have to be removed during a storm. It also became apparent that public opinion was against any structure that would block the view of the beaches and water from the adjoining properties immediately north of the roads. This was voiced in public meetings and also from agencies that were involved in the study. To maintain some level of support for this defense, it was decided to raise the roadways an average of six feet. This allowed reasonable road intersection

construction while maintaining the aesthetic view of the water and would not be perceived as a high seawall along the coast. A review of the typical roadway elevations allowed raising the roadways in Jackson and Hancock County to Elevation 11.0 and Highway 90 in Harrison County to Elevation 16.0. It was decided to study these elevations without other options as the main part of LOD-3 with the understanding that these structures would not provide protection from large storms. As described above, the LOD-2 dunes could also be constructed against the elevated roadway to help protect the toe of the structural wall associated with the road.

This line of defense would be connected to LOD-4, described below, at the mouth of Biloxi Bay and St. Louis Bay. It would also extend northward to higher ground or to LOD- 4 in Jackson County and Hancock County. The bays are an inlet for storm surge that would be controlled by surge gates as part of LOD- 4. It was also recognized that if LOD-3 was constructed without LOD-4, surge gates across the bays would have to be included as part of LOD-3.

As the first structural defense, LOD-3 will exclude some areas that may be considered potential areas of retreat or have other non-structural solutions. This may be due to low population density, ecological sensitivity, areas that contain numerous waterway crossings or areas that could not function with a structural barrier in place. In Jackson County, LOD-3 will encompass the southern portion of Ocean Springs, but due to extended marshes and streams, it will extend northeastward from near the eastern end of East Beach Road to higher ground. Areas east of this location contain numerous marshes, streams, and scattered development. Ring levees will be evaluated for housing developments in some areas. Further east in Jackson County are the cities of Gautier, Pascagoula and Moss Point. The presence of numerous streams and inlets will make a continuous barrier very difficult and these areas are also envisioned to have individual ring levees. While alignments were selected that provided the maximum protection for the most developed areas, some portions could be excluded due to cost and technical issues with closing off drainages. Redrawing the alignments would place some areas into a non-structural solution and could be considered as potential options for further study. These alternate alignments were drawn for Pascagoula/Moss Point, Bell Fontaine, and Gulf Park Estates.

At the western end of LOD-3, the barrier will extend down North Beach Boulevard for several miles to near Bayou Caddy and then turn north to tie in with higher ground. By following this path, the existing roadway will provide an alignment and it will encompass much of the developed waterfront from Bay St. Louis to Waveland, MS. Further west, the town of Pearlington will be evaluated for construction of a ring levee.

As with the main portion of LOD-3, the ring levees were initially considered with the same three elevations of 12.0, 18.0 and 24.0. Closer study revealed that in many cases, the elevation 12.0 was too low based on existing ground surfaces and the elevation 24.0 may not be high enough to be certified by FEMA for a 100-year storm event. The elevations to be studied for the ring levees then was changed to 20.0 and 30.0 with the assumption that the 100-year event would fall between these elevations and that the elevation 30.0 design would be sufficiently high for even a 500-year event. A 100-year minimum event is necessary for levee certification by FEMA.

While many options were reviewed for the type of structure to be used along the roadways, a simple elevated roadway associated with an extension of the existing seawall was chosen for reliability reasons. A structure that did not mainly rely on powered systems or with multiple moving systems was deemed more suitable for the purposes of this line of defense. Numerous conceptual designs were considered including inflatable barriers, concrete sidewalks or roadways that could be hydraulically rotated upwards to form a seawall, sliding panel gates within a seawall, and structural concrete seawalls. The ring levees were all designed as earthen structures. It should be understood that all of these LOD-3 structures would provide less protection than would be required for a Camille

or Katrina-like storm. LOD-3 storm damage reduction levels are limited and will be determined based on public and local government acceptance and the amount of risk that Mississippi is willing to accept.

As previously mentioned, this LOD-3 is dependent on having the ability of closure across the two bays to prevent the storm surge from running inside the mouths of the bays. While the plan calls for surge gates to be associated with LOD-4, surge gates would also have to be incorporated with LOD-3 if LOD-4 is not selected as an alternative. The top elevation of surge gates used solely for LOD-3 would be of an elevation that would be compatible with the rest of that barrier.

Interior drainage behind these barriers must be considered. Any large rainfall event would require that the water trapped behind the barrier have a means to drain or even be mechanically pumped. The amount of storage that a given watershed could provide behind a barrier during surge conditions will vary. The means to block surge but allow drainage as the surge passes may include conduits with flap valves or gated culverts up to surge gates across large bodies of water. The areas where pumping is required are numerous, but necessary to prevent residual damages associated with this blockage of normal drainage.

The pumping stations, where required, must survive any storm damage and continue to operate until the storm event has passed. This will require hardened structures to house the pumps and power systems, and be constructed to a height that corresponds to the risk associated with that line of defense.

3.3.1 Hancock County Ring Levees, Pearlington

Pearlington is a small town located in the western part of Hancock County as shown in Figure 3.3.1-1. The town lies on the bank of the Pearl River about 5 miles from the Mississippi Sound. Ground elevations over most of the residential and business areas are very low between elevations 6-10 ft NAVD88. Pearlington was an extremely hard hit area during the 2005 hurricane season. Water reached a depth of 10-14 feet over the whole community. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A and Option B.

Figure 3.3.1-1. Vicinity Map, Pearlington

3.3.1.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the most densely populated areas of Pearlington along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 ft NAVD88 with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.1.2 Option B - elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 ft NAVD88. The difference between the description of this option and the preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.1.3 Project Description

Figure 3.3.1.3-1 shows the location of the proposed project alternatives. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.1.3-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further

studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

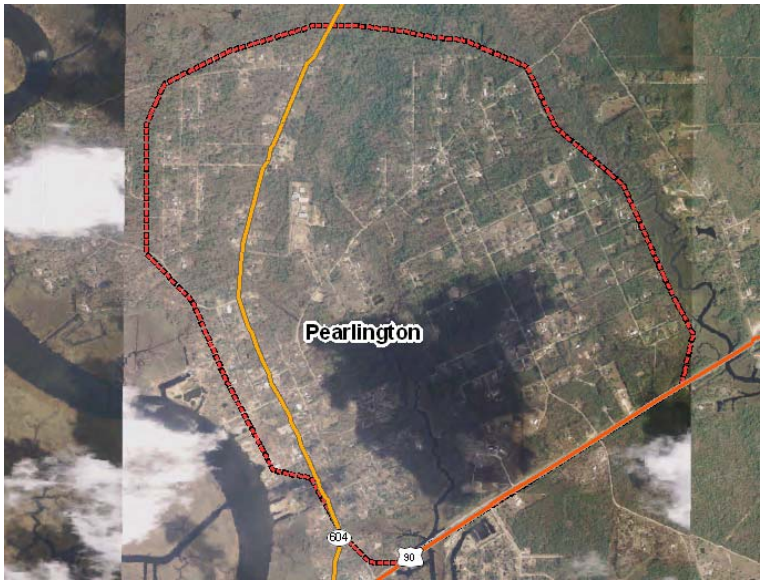

Figure 3.3.1.3-1. Pearlington Ring Levee

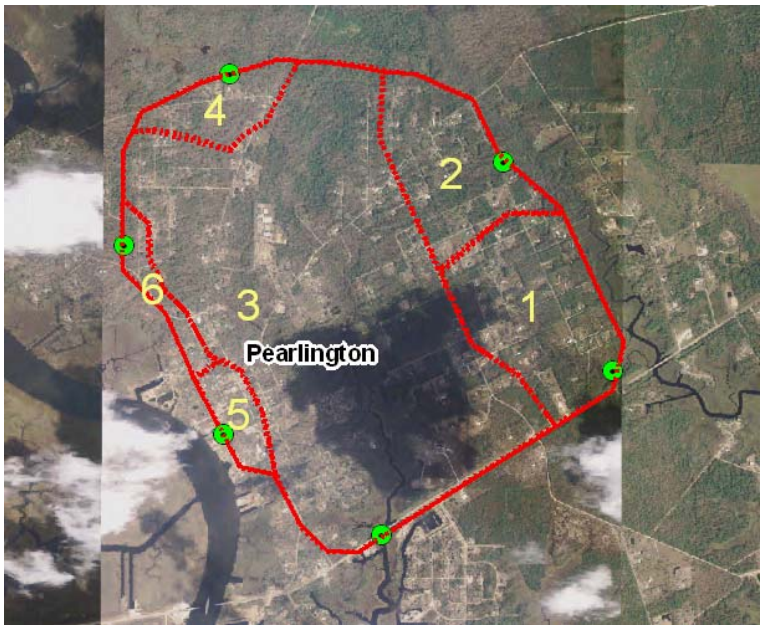

Figure 3.3.1.3-2. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site borrow sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed. Pump facilities will be required at 6 locations.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around the Pearlington area, 18 roadway intersections would have to be accommodated. For this study it was estimated that all 18 would require swing gate structures.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills or rivulets will be filled and damaged revetment will be repaired.

3.3.1.4 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Pearlington Ring Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches, and 6 culvert/pump station facilities.

Based on the footprint of the Option A 20.0 foot elevation, it was determined that approximately 111 parcels and 28 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 6 pump stations will require approximately 0.23 of an acre each for a total of 1.38 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 28 relocations. For cost purposes, the relocations are assumed to be residential.

Based on the footprint of the Option B 30.0 foot elevation, it was determined that 120 parcels and 30 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 6 pump stations will require approximately 0.23 of an acre each for a total of 1.38 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 30 relocations. For cost purposes, the relocations are assumed to be residential.

Ditches that will be constructed to provide drainage for the interior of the ring levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Any modifications to the roadways will most probably need to be accomplished under a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.1.5 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.1.6 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.1.7 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.1.8 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project. Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.1.9 Government Owned Property

There are no known Government owned lands in the proposed project.

3.3.1.10 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.1.11 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.1.12 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.1.13 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person

may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 28 relocations in Option A and approximately 30 relocations in Option B. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.1.14 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.1.15 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.1.16 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all

such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.1.17 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.1.17-1. The real estate cost estimates at Table 3.3.1.17-2 and Table 3.3.1.17-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.1.17-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	111	28	8,883,000
Option B - 30.0	120	30	9,340,000

	Rounded				**9,340,000**

3.3.1.18 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A Real Estate Relocation Plan should be prepared during PED to address potential relocation activity under PL.91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.1.19 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.1.19-1 and 3.3.1.19-2 shows the CWBS for real estate activities.

3.3.2 Hancock County Ring Levees, Bay St. Louis

The City of Bay St. Louis is located in the eastern part of Hancock County as shown in Figure 3.3.2-1. The town is bordered by the Mississippi Sound. The Shoreline Park subdivision area to the north of Bay St. Louis is very low at elevations 4-6 ft NAVD88 and subject to frequent flooding from storm surge. During the 2005 hurricane season, water reached a depth of 10-20 ft over the coastal community. For purposes of providing protection to residential and commercial structures for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A and Option B.

Figure 3.3.2-1. Vicinity Map, Bay St. Louis

3.3.2.1 Option A - Elevation 20.0 NAVD88

This option consists of an earthen dike around the most densely populated areas of Bay St. Louis along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.2.2 Option B - Elevation 30.0 NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.2.3 Project Description

Figure 3.3.2.3-1 below shows the location of the proposed project alternatives. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.2.3-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further

studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

Figure 3.3.2.3-1. Bay St. Louis Ring Levee

Figure 3.3.2.3-2. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed. Pump facilities are required at 12 locations.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around the Bay St. Louis area to elevation 20.0, 21 roadway intersections would have to be accommodated. For this study it was estimated that of this number, 4 would require swing gate structures, with the rest requiring roller gates of various heights. With the installation of a ring levee around the Bay St. Louis area to elevation 30, 69 roadway intersections would have to be accommodated, and it was estimated that of this number, 62 would require swing gate structures, with the remaining 7 requiring roller gates of various heights.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.2.4 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Bay St. Louis Ring Levees include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and 12 culvert/pump station facilities.

Based on the footprint of the Option A 20.0 foot elevation, it was determined that approximately 442 parcels and 149 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 11 pump stations will require approximately 0.23 of an acre each for a total of 2.53 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 149 relocations.

Based on the footprint of the Option B 30.0 foot elevation, it was determined that 576 parcels and 212 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 12 pump stations will require approximately 0.23 of an acre each for a total of 2.76 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 212 relocations.

Any modifications to the roadways will most probably need to be accomplished under a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.2.5 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee. An assumption is made that this work will be accomplished under a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.2.6 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.2.7 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.2.8 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.2.9 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.2.10 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.2.11 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.2.12 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.2.13 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 149 relocations in Option A and approximately 212 relocations in Option B. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.2.14 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.2.15 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.2.16 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.2.17 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.2.17-1. The real estate cost estimates at Table 3.3.2.17-2 and Table 3.3.2.17-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.2.17-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost

	Rounded				**156,364,000**

3.3.2.18 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A Real Estate Relocation Plan should be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.2.19 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.2.19-1 and 3.3.2.19-2 shows the CWBS for real estate activities.

3.3.3 Hancock County, Elevated Roadway

Residential and business areas along the coast in Hancock County are susceptible to storm surge damage. The beach front road in Hancock County joins the communities of Bay St. Louis and Waveland at the mouth of St. Louis Bay. Drainage at Bay St. Louis and Waveland is to the Mississippi Sound to the south and to tributaries of St. Louis Bay to the north. The Shoreline Park subdivision area to the north of Bay St. Louis is very low at elevations and subject to frequent flooding from storm surge. Impacts from the 2005 hurricanes were devastating to the area. A damage reduction option to raise the beach front road in Hancock County to elevation 11ft NAVD88 was evaluated. The location of the project is shown in Figure 3.3.3-1.

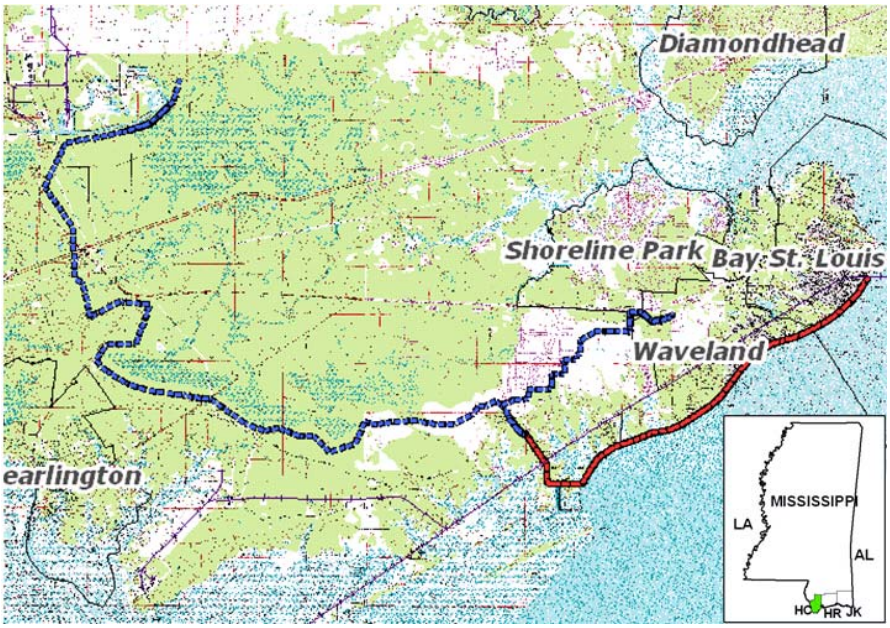

Figure 3.3.3-1. Vicinity Map near Waveland

3.3.3.1 Project Description

The proposed road alignment is shown in red in Figure 3.3.3-1. The option consists of more than one element and function. This option also contains a provision for a levee at elevation 16 ft NAVD88, shown in blue in the above Figure 3.3.3-1. The elevation 16 ft NAVD88 levee functions in coordination with the Harrison County Elevated Hwy 90 Roadway also at elevation 16 ft NAVD and the St. Louis Bay closure structure. This option consists of raising the beach front road to elevation 11 ft NAVD88 in the Bay St. Louis/Waveland area as shown on the following Figure 3.3.3.1-1, along with the internal sub-basins and levee culvert/pump locations. There is one culvert but no pumps associated with the Elevation 16 ft NAVD88 levee as shown on Figure 3.3.3.1-2. This levee runs mostly along the ridge line so the drainage is away from the levee. A small boat access structure is also shown at the mouth of one basin. Rising sector gates will be provided at this gate allowing shallow draft traffic most of the time. The gate will be closed prior to hurricane storm surge.

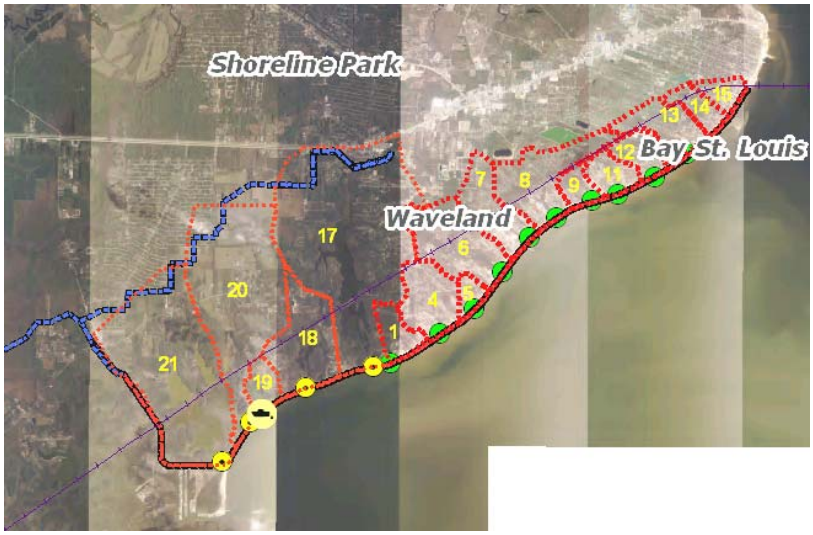

Figure 3.3.3.1-1. Pump/Culvert/Boat Access Site Locations and Sub-basins

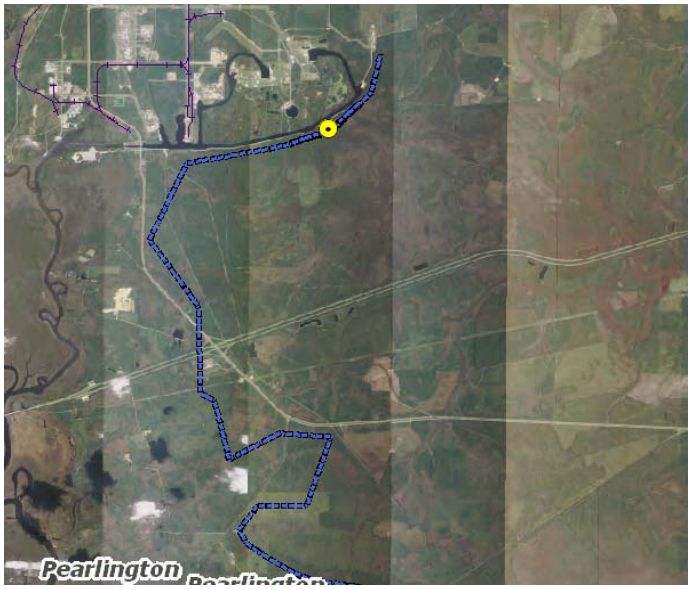

Figure 3.3.3.1-2. Culvert Site Location

The Line 3 defense elevates the roadway and accompanying seawall by extending the seaway at its present slope to grade, creating the roadway sub grade then, sloping the backside to one vertical to three horizontal side slopes with a twenty five foot toe width for access and drainage. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The embankment will be constructed of sand clay materials obtained from off site

commercial sources, trucked to the work area. The final surface on the back side will be armored by the placement of 12 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the road. All non critical surface areas will be subsequently covered by grassing. Road crossings will incorporate ramping over the embankment where the surface elevation is near that of the crest elevation. Drainage on the interior of the raised roadway would be collected at the highway and channeled to culverts. Drainage ditches along the toe of the highway will be required to assure that smaller basins can be drained to a culvert/pump site. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts were closed because of high water in the sound.

The features that require periodic operations will be the raising and lowering of sluice gates and the functioning flap gates, grass cutting of the embankment slopes and toe areas and the filling of rilled areas within the embankment due to surface erosion.

3.3.3.2 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Hancock County Elevated Road measure include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to raise a road and construct an earthen levee and 10 culvert/pump station facilities. Based on the project footprint, it was determined that approximately 427 parcels and 66 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 10 pump stations will require approximately 0.23 of an acre each for a total of 2.3 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 66 relocations.

Ditches that will be constructed to provide drainage for the levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Raising of the roadway will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

In some areas the levee alignment would cross a moderately sized water course where it is apparent that boats currently traverse the area. To allow continued free boat access to areas behind the levee these water courses will be fitted with a scaled down adaptation of the larger rising sector gate structure used for the bay barriers at Biloxi and Bay St. Louis. A small boat access structure is shown at the mouth of one basin in the project footprint. Rising sector gates will be provided at this gate allowing shallow draft traffic most of the time. The gate will be closed prior to hurricane storm surge. No additional real estate interest is identified for boat access points as they fall within the footprint of the project and impacted parcels are included in the total that is projected. For those lands required for construction that lay below the mean high water mark, navigation servitude will apply.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with

the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the project. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.3.3 Utility/Facility Relocation

The plan calls for elevation of the beachfront road. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.3.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.3.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.3.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot

receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.3.7 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.3.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.3.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.3.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.3.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 66 relocations in this alternative. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.3.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.3.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.3.14 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.3.15 Real Estate Estimate

The real estate cost estimate at Table 3.3.3.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions,

analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.3.15-1.
LOD3 Hancock County Elevated Road Estimate

a. Lands and Improvements/Permits

		Totals			**44,938,806**
		Rounded			**44,939,000**

3.3.3.16 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.3.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.3.3.17-1 shows the CWBS for real estate activities.

3.3.4 Harrison County, Elevated Roadway

Residential and business areas along the coast in Harrison County are susceptible to storm surge damage. In Harrison County, ground elevations over most of the residential and business areas vary between elevation 8-12 feet NAVD88 on the coast and rising within 1000 feet to elevation 30-36 along a ridge parallel to the coastline, then decreasing to the north. A damage reduction option to raise Highway 90 to elevation 16 feet NAVD88 was evaluated. The location of the project is shown in Figure 3.3.4-1.

Figure 3.3.4-1. Vicinity Map, Harrison County

3.3.4.1 Project Description

The proposed project is shown in red in Figures 3.3.4.1-1 through Figure 3.3.4.1-4. Highway 90 in Harrison County extends from Biloxi Bay to pass Christian.

Figure 3.3.4.1-1. Pump/Culvert/Sub-basin Site Locations, Harrison County

Figure 3.3.4.1-2. Pump/Culvert/Sub-basin Site Locations, Harrison County

Figure 3.3.4.1-3. Pump/Culvert/Sub-basin Site Locations, Harrison County

Figure 3.3.4.1-4. Pump/Culvert/Sub-basin Site Locations, Harrison County

This option consists of raising US Highway 90 along the coast of Harrison County to elevation 16 feet NAVD88 along with the internal sub-basins and levee culvert/pump locations as shown above. The Line 3 defense elevates the roadway and accompanying seawall by extending the seaway at its present slope to grade, creating the roadway sub grade then, sloping the backside to one vertical to three horizontal side slopes with a twenty five foot toe width for access and drainage. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The embankment will be constructed of sand clay materials obtained from off site commercial sources, trucked to the work area. The final surface on the back side will be armored by the placement of 12 inch thick gabion mattress filled with small stone for erosion protection during an

event that overtops the road. All non critical surface areas will be subsequently covered by grassing. Road crossings will incorporate ramping over the embankment where the surface elevation is near that of the crest elevation. Drainage on the interior of the raised roadway would be collected at the highway and channeled to culverts Drainage ditches along the toe of the highway, will be required to assure that smaller basins can be drained to a culvert/pump site. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts were closed because of high water in the sound.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations.

3.3.4.2 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Harrison County Elevated Road measure include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to raise a road and construct an earthen levee, drainage ditches and 15 culvert/pump station facilities. Based on the project footprint, it was determined that approximately 1031 parcels and 80 structures would be impacted. The acreage to be acquired is unknown. It is known that the 15 pump stations will require approximately 0.23 of an acre each for a total of 3.45 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 80 relocations.

Ditches that will be constructed to provide drainage for the levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Raising of the roadway and relocation of any utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the project. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.4.3 Utility/Facility Relocation

The plan calls for elevation of Highway 90. Some removal/relocation of utilities may be required. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.4.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.4.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.4.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.4.7 Government Owned Property

There 4 Government owned parcels within the footprint of the project. In viewing the footprint, it appears that these parcels will be minimally impacted where they abut Highway 90. Land and structure values are not listed in the public records. Ownership is listed in public records as US Govt, US Veterans Hospital, and United States of America. Specific impacts to Government owned lands will be determined during PED.

3.3.4.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.4.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.4.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.4.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 80 relocations in this alternative. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.4.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.4.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60

days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.4.14 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.4.15 Real Estate Estimate

The real estate cost estimate at Table 3.3.4.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions,

analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.4.15-1.
LOD3 Harrison County Elevated Road Estimate

a. Lands and Improvements/Permits					
1016 Ownerships for Levee, 80 Improvements					375,464,802
15 Pump Stations					270,004
1031 Ownerships				Subtotal	375,734,806
b. Mineral Rights					0
c. Damages					0
d. P.L. 91-646 Relocation costs – 80 relocations					2,240,000
e. Administrative Cost					0
		Relocation	Acquisition	Total	
	Federal	120,000	2,577,500	2,697,500	
	Non-Federal	480,000	20,620,000	21,100,000	
		600,000	23,197,500	23,797,500	
Subtotal					401,772,306
Contingencies (25%)					100,443,077
		Totals			**502,215,383**
		Rounded			**502,215,000**

3.3.4.16 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.4.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.3.4.17-1 shows the CWBS for real estate activities.

3.3.5 Harrison County Forrest Heights Levee, City of Gulfport

The Forrest Heights community is located in an area known as North Gulfport within the city of Gulfport on the Mississippi Gulf Coast. The residential community lies on the bank of Turkey Creek about 2.6 miles from the mouth at Bernard Bayou, and has frequently been inundated by flood waters due to storm surges from the Mississippi Sound and from inland flooding along the lower Turkey Creek floodplain. Turkey Creek has a tendency to frequently exceed its stream channel capacity and flood adjacent low-lying areas. Water reached a depth of 2-8 feet over the entire community during Hurricane Katrina inundation. Ground elevations over most of the residential area are between elevations 10-14 feet NAVD88. Drainage is mostly along streets and through natural drainage ways to the Turkey Creek. A previous evaluation recommended the construction of an earthen levee to protect this area from storm surge flooding. The Forrest Heights levee is proposed to be constructed as a pilot project for the MsCIP comprehensive plan. The levee will address the combination of storm surge protection and inland surge protection. The levee is intended to be constructed to a height such that the levee might be certified under the National Flood Insurance Program. A preliminary engineering analysis suggests a levee built to approximately elevation 21 ft NAVD88 would satisfy or exceed certification elevation criteria. The location of the levee is shown in Figure 3.3.5-1. The options in this study are identified as Option A and Option B. The levees were evaluated at elevations 17 ft NAVD88 and 21 ft NAVD88. The top width was assumed 12 ft with side slopes of 1 vertical to 3 horizontal.

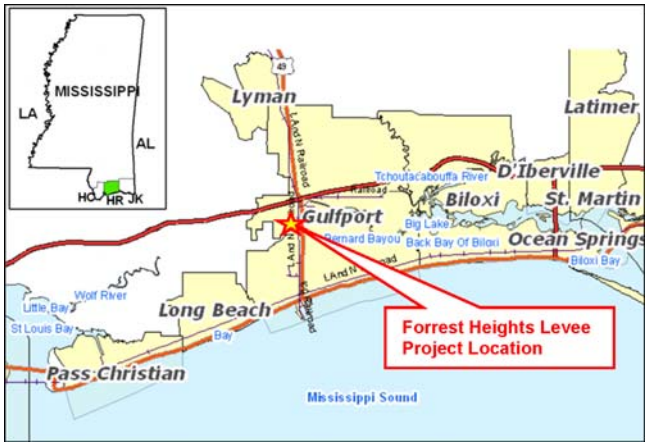

Figure 3.3.5-1. Vicinity Map

3.3.5.1 Option A - Elevation 17.0 ft NAVD88

This option consists of an earthen dike around the Forrest Heights community along with the levee culvert/interior detention location. It generally will be trapezoidal in shape with an elevation of 17.0 feet and a top width of 12 ft and slopes of 1 vertical to 3 horizontal on both sides. The total length of the levee will be approximately 7,900 feet. The recommended plan includes selective clearing and snagging as a measure to prevent increases in water surface elevations upstream that would occur due to the placement of the levees in the floodplain.

3.3.5.2 Option B - Elevation 21.0 ft NAVD88

This option consists of an earthen levee around northern, western, and southern sides of the Forrest Heights community. Because of the height of the levee, the eastern side will be constructed with a concrete “T”-wall structure. The “T” wall will take less space than an earthen levee and encroach less into property along the alignment. Closure gates across the two access roads to the subdivision will be required. The lengths of the levee culverts will be slightly longer than those used in Option A. Other features and methods of analysis are the same.

The levee alignment for both Option A and B is generally the same and is shown in Figure 3.3.5.2-1.

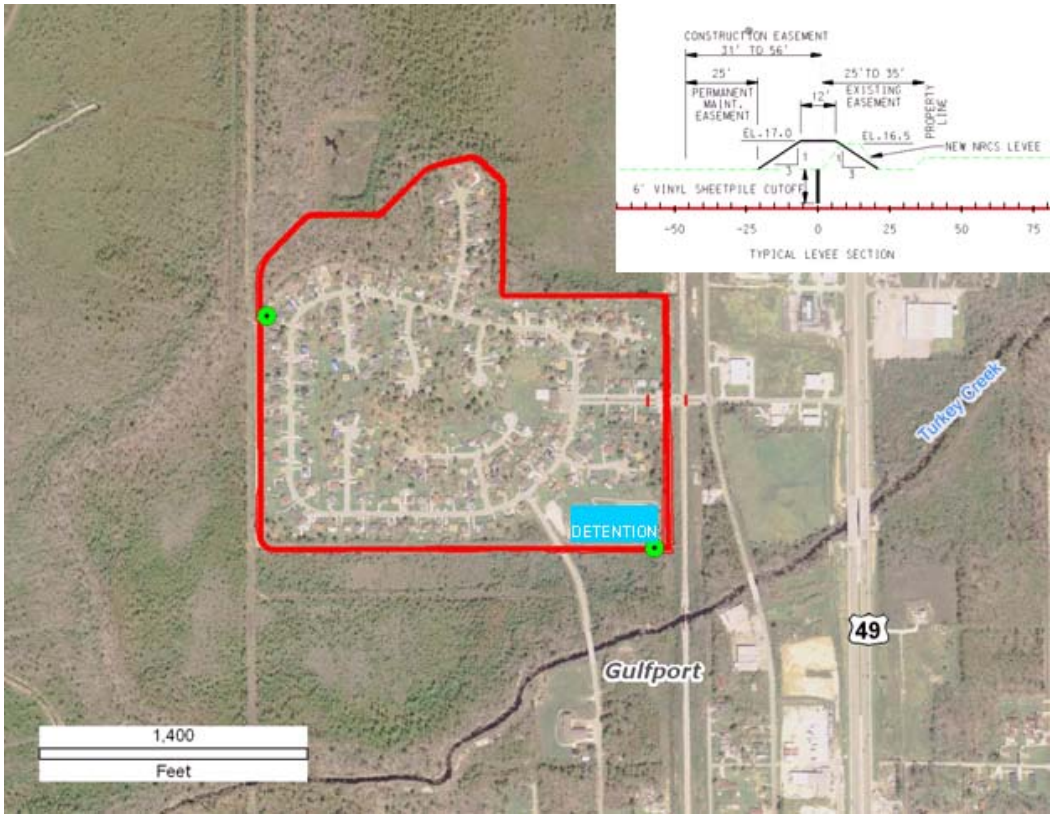

Figure 3.3.5.2-1. Levee Alignment with Detention Site Location

3.3.5.3 Project Description

As described above, the levee will be an earthen berm constructed either at elevation 17.0 feet or 21.0 feet along with culvert/interior detention locations. Interior flooding on the landward side of the levee will be improved by adding a storm water detention basin and pumping facility. The detention area will hold storm water until the creek water level recedes and water can drain through the culvert. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided in the levee for control in the event the flap gate malfunctions.

The detention basin would have an area of approximately 3 acres but would not be excavated. The area is the lowest site in the subdivision and is presently used for recreation facilities such as baseball and tennis.

The Recommended Plan includes selective clearing and snagging for approximately 4.5 miles from the mouth of Turkey Creek at Bernard Bayou to the upstream limits as shown in Figure 3.3.5.3-1. Selective clearing and snagging would remove obstructions such as debris dams and excessive sedimentation that hinders the flow through the Turkey Creek channel. While the selective clearing and snagging component of the plan does not eliminate flooding along Turkey Creek, the plan does reduce flood damages along the creek and at the upper end of the canals at 28th Street. The main purpose of the selective clearing and snagging is to make sure that induced damages do not occur due to the construction of the recommended levees. Only debris, snags and sediment that obstruct the flow will be removed. Material to be removed includes: 1) fine sediment accumulations that obstruct flows and alter flow patterns; 2) Debris blockages that currently or in the near future cause obstructed flow and altered flow patterns; and 3) Rooted trees that obstruct flow or need to be cleared for equipment access. Access areas that are cleared will be reestablished at the conclusion of the selective clearing and snagging activities. Some access points, however, may remain for the non-Federal sponsor to use for maintenance activity of the completed project. The existing bank alignment along the entire reach will not be changed, including the downstream reaches of Turkey Creek along the meander bends. Specific reaches to be cleared and snagged will be identified by an interdisciplinary team prior to construction.

Figure 3.3.5.3-1. Channel Clearing and Snagging Limits

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a twelve foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box structures fitted with flap gates and sluice gates to provide protection from high water outside the levee.

With the installation of a ring levee around the Forrest Heights community at Option A, elevation 17.0 or Option B, elevation 21.0, 2 roadway intersections would have to be accommodated. For this study it was estimated that for Option A both roadway entrances could use ramps for crossing the restored levee. For Option B both roadway entrances would use sliding flood gates.

Operation and maintenance activities for this project will be required on an annual basis. All gates will be operated to assure proper working order. Debris and shoaled sediment will be removed from the interior ponding area. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.5.4 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Forrest Heights Levees include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and detention ponding area. Based on the footprint of the Option A 17.0 foot elevation, it was determined that approximately 18 parcels and 2 structures will be impacted. The acreage to be acquired for the levee is unknown. It is known that the detention ponding area would require approximately 3.0 acres. Lands required for construction of the levee and the detention pond will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 2 relocations. Approximately 55 acres will be acquired in Channel Improvement Easements from approximately 48 landowners.

Based on the footprint of the Option B 30.0 foot elevation, it was determined that the same number of parcels and structures will be impacted as for Option A, but the easement area required for the levee will be extended to permit construction of the higher levee.

Ditches that will be constructed to provide drainage for the interior of the ring levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with

the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.5.5 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.5.6 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.5.7 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.5.8 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the

non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.5.9 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.5.10 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.5.11 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.5.12 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.5.13 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 2 relocations in Option A and approximately 2 relocations in Option B. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.5.14 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.5.15 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.5.16 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. The Channel Improvements Easement will be used for clearing and snagging work. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

CHANNEL IMPROVEMENT EASEMENT.

A perpetual and assignable right and easement to construct, operate, and maintain channel improvement works on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____) for the purposes as authorized by the Act of Congress approved _____,

including the right to clear, cut, fell, remove and dispose of any and all timber, trees, underbrush, buildings, improvements and/or other obstructions there from; to excavate: dredge, cut away, and remove any or all of said land and to place thereon dredge or spoil material; and for such other purposes as may be required in connection with said work of improvement; reserving, however, to the owners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements far public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.5.17 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.5.17-1. The real estate estimates at Tables 3.3.5.17-2 and 3.3.5.17-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.5.17-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 17.0	67	2	$2,571,000
Option B - 21.0	67	4	$2,649,000

3.3.5.18 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with

these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.5.19 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.5.19-1 and 3.3.5.19-2 shows the CWBS for real estate activities.

3.3.6 Jackson County, Elevated Roadway

Residential and business areas along the coast in Jackson County are susceptible to storm surge damage. The city of Ocean Springs lies at the eastern side of the Back Bay of Biloxi. Ground elevations over most of the residential and business areas vary between elevations 16-24 ft NAVD88, with houses along the coast between 8-16 ft NAVD88. This option entails the raising of the Beach Road and the adjoining seawall to Elevation 11.00 from Highway 90 eastward to the Jackson County Marina. The project also provides for all utility infrastructures such as water, sewer, storm drain, gas and electric lines to be removed and reinstalled to meet the new grades. The project location is shown in Figure3.3.6-1 with the roadway in red.

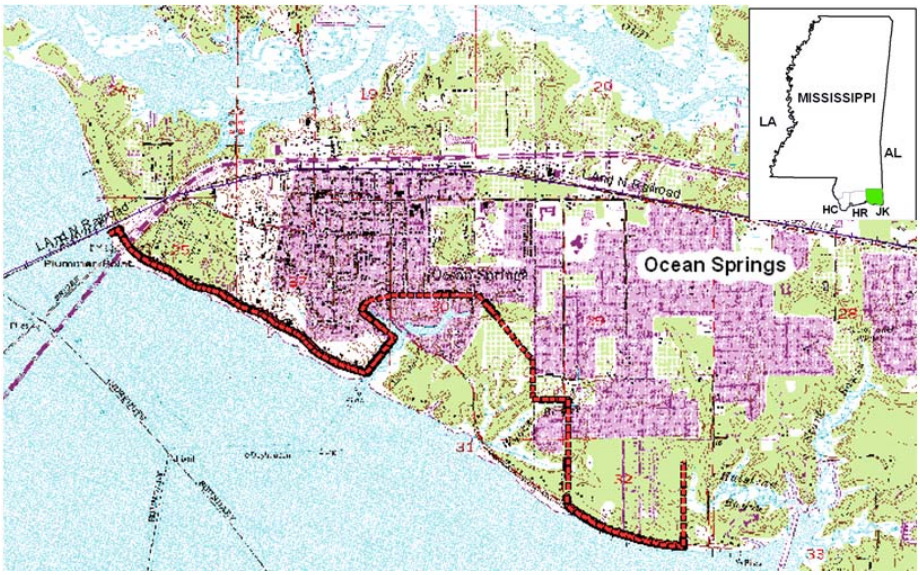

Figure 3.3.6-1. Vicinity Map, Ocean Springs

3.3.6.1 Project Description

This option consists of raising the beach road to elevation 11 feet NAVD88 in Ocean Springs. The internal sub-basins and levee culvert/pump locations are shown on Figure 3.3.6.1-1. Drainage on the interior of the raised highway would be collected at the highway and channeled to culverts placed at locations shown below. Drainage Ditches along the toe of the highway will be required to assure that smaller basins can be drained to a culvert/pump site.

Figure 3.3.6.1-1. Pump/Culvert/Sub-basin Site Location

The Line 3 defense elevates the roadway and accompanying seawall by extending the seaway at its present slope to grade, creating the roadway sub grade then, sloping the backside to one vertical to three horizontal side slopes with a twenty five foot toe width for access and drainage. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The embankment will be constructed of sand clay materials obtained from off site commercial sources, trucked to the work area. The final surface on the back side will be armored by the placement of 12 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the road. All non critical surface areas will be subsequently covered by grassing. Road crossings will incorporate ramping over the embankment where the surface elevation is near that of the crest elevation. Drainage on the interior of the raised roadway would be collected at the highway and channeled to culverts. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts were closed because of high water in the sound.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations.

3.3.6.2 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Jackson County Elevated Road measure include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to raise a road and construct an earthen levee, drainage ditches and 7 culvert/pump station facilities. Based on the project footprint, it was determined that approximately 137 parcels and 55 structures would be impacted. The acreage to be acquired is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 55 relocations.

Ditches that will be constructed to provide drainage for the levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Raising of the roadway and relocation of any utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the project. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an

upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.6.3 Utility/Facility Relocation

The plan calls for elevation of Highway 90. Some removal/relocation of utilities may be required. An assumption is made that this work will be accomplished under a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.6.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.6.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.6.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.6.7 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.6.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.6.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.6.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.6.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 55 relocations in this alternative. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.6.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.6.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey,

appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.6.14 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.6.15 Real Estate Estimate

The real estate cost estimate at Table 3.3.6.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.6.15-1.
LOD3 Jackson County Elevated Road Estimate

a. Lands and Improvements/Permits

	Non-Federal	330,000	2,740,000	3,070,000	
		412,500	3,082,500	3,495,000	
Subtotal					31,204,091
Contingencies (25%)					7,801,023
		Totals			**39,005,114**
		Rounded			**39,005,000**

3.3.6.16 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.6.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.3.6.17-1 shows the CWBS for real estate activities.

3.3.7 Jackson County Ring Levees, Ocean Springs

Several high density residential and business areas in Jackson County were identified. They are Ocean Springs, Gulf Park, Belle Fontaine, Gautier and Pascagoula/Moss Point. The city of Ocean Springs is located in the western part of Jackson County and lies at the eastern side of the Back Bay of Biloxi as shown in Figure 3.3.7-1. Ground elevations over most of the residential and business areas vary between elevations 16-24 feet NAVD88, with houses along the coast at between 8-16 feet NAVD88. These areas are subject to damage from storm surges associated with hurricanes. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A and Option B. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88. The top width was assumed 15 ft with side slopes of 1 vertical to 3 horizontal.

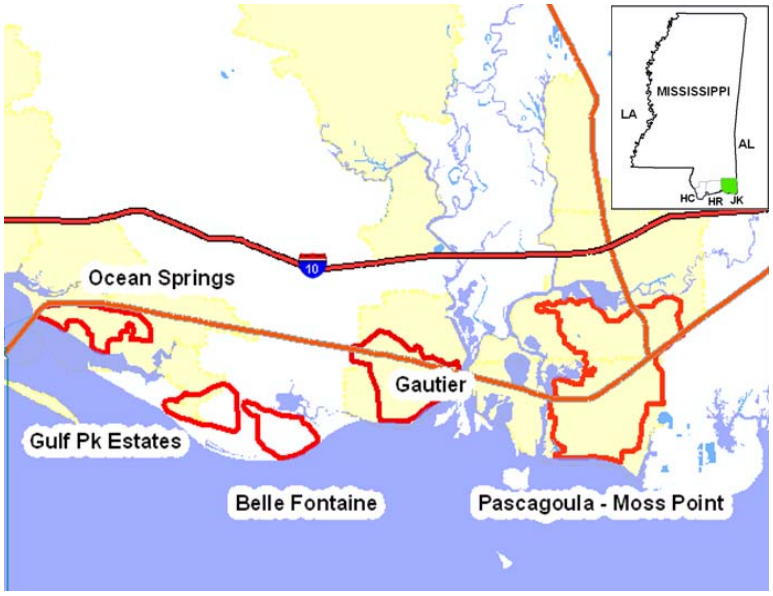

Figure 3.3.7-1. Vicinity Map, Ocean Springs, MS

3.3.7.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the most densely populated areas of Ocean Springs along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.7.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the

height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.7.3 Project Description

Figure 3.3.7.3-1 shows the location of the proposed project alternatives. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.7.3-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

Figure 3.3.7.3-1. Ocean Springs Ring Levee

Figure 3.3.7.3-2. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. Pump facilities are required at 14 locations. As any flood barrier is constructed the natural groundwater runoff would be inhibited. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used

including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around the Ocean Springs area at Option A, elevation 20.0, 24 roadway intersections would have to be accommodated. For this study it was estimated that 6 roller gate structures and 18 would require swing gate structures would be required. At Option B, elevation 30.0, 76 roadway intersections would have to be accommodated, and it was estimated that 6 roller gate structures and 70 swing gate structures would be required

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.7.4 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Ocean Spring Ring Levees include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and 14 culvert/pump station facilities.

Based on the footprint of the Option A 20.0 foot elevation, it was determined that approximately 197 parcels and 83 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 14 pump stations will require approximately 0.23 of an acre each for a total of 3.22 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 83 relocations.

Based on the footprint of the Option B 30.0 foot elevation, it was determined that 576 parcels and 312 structures are impacted. The acreage to be acquired for the levee is unknown. It is known that the 14 pump stations would require approximately 0.23 of an acre each for a total of 3.22 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 312 relocations.

Ditches that will be constructed to provide drainage for the interior of the ring levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if

disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.7.5 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.7.6 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.7.7 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.7.8 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the

purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.7.9 Government Owned Property

There 11 Government owned parcels within the footprint of the project. In viewing the footprint, it appears that these parcels will be minimally impacted by construction of the levee for the most part. Three of the parcels may be impacted to a greater degree. Land values are listed in the public records but no improvement values are listed. Ownership is listed in public records as US of America and United States of America. Specific impacts to Government owned lands will be determined during PED.

3.3.7.10 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.7.11 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.7.12 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.7.13 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 83 relocations in Option A and approximately 312 relocations in Option B. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.7.14 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area

to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.7.15 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.7.16 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement

hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.7.17 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.7.17-1. The real estate estimates at Tables 3.3.7.17-2 and 3.3.7.17-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.7.17-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	197	83	$43,609,000
Option B - 30.0	576	312	$119,542,000

	Totals			**119,542,130**
	Rounded			**119,542,000**

3.3.7.18 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.7.19 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.7.19-1 and 3.3.7.19-2 shows the CWBS for real estate activities.

3.3.8 Jackson County Ring Levees, Gulf Park

Several high density residential and business areas in Jackson County were identified. They are Ocean Springs, Gulf Park, Belle Fontaine, Gautier and Pascagoula/Moss Point. Gulf Park Estates Subdivision is located adjacent to and east of Ocean Springs. The area of study for the ring levee is bounded by Simmons Bayou on the north and the Mississippi Sound on the south. The location of the Gulf Park Estate ring levee is shown in Figure 3.3.8-1. Ground elevations over most of the residential areas vary between elevations 10-20 feet NAVD88. These areas are subject to damage from storm surges associated with hurricanes. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A, Option B, Option C and Option D. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88. The top width was assumed 15 ft with side slopes of 1 vertical to 3 horizontal.

Figure 3.3.8-1. Vicinity Map, Gulf Park Estates

3.3.8.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the most densely populated areas of Gulf Park Estates along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.8.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.8.3 Option C - Alternate Alignment, Elevation 20.0 ft NAVD88

Option C consists of an earthen levee at elevation 20.0 feet in an alignment slightly different from the alignment for Options A and B. Additionally, the lands that lay between the alignment of Option A and the alternate alignment, Option C will be acquired as a buffer zone in this option.

3.3.8.4 Option D - Alternate Alignment, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option C, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option C is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts. As above, the buffer zone lands will be acquired.

3.3.8.5 Project Description

Figure 3.3.8.5-1 shows the location of the proposed project alternatives with the alternate alignment representing Options C and D. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.8.5-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

Figure 3.3.8.5-1. Gulf Park Estates Ring Levee

Figure 3.3.8.5-2. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study the culverts were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed. Pump facilities are required at 8 locations for Options A and B and at 9 locations for Options C and D.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used

including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around Gulf Park Estates at Option A, elevation 20.0, 20 roadway intersections would have to be accommodated. For this study it was estimated that 2 roller gate structures and 18 would require swing gate structures would be required. At Option B, elevation 30.0, 13 roadway intersections would have to be accommodated, and it was estimated that all 13 would require swing gate structures. At Option C, elevations 20.0, 18 roadway gates for intersections would have to be accommodated, and 14 would require swing gate structures with the remaining 4 requiring roller gates of varying heights. For Option D, elevation 30.0**,** 15 roadway intersections would have to be accommodated and all 15 would require swing gate structures.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.8.6 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Gulf Park Estates Ring Levees include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire buffer zone lands, construct an earthen levee, drainage ditches and 8 - 9 culvert/pump station facilities depending on the option.

Based on the footprint of Option A, 20.0 foot elevation, it was determined that approximately 354 parcels and 62 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 8 pump stations will require approximately 0.23 of an acre each for a total of 1.84 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 62 relocations.

Based on the footprint of Option B, 30.0 foot elevation, it was determined that approximately 399 parcels and 66 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 8 pump stations will require approximately 0.23 of an acre each for a total of 1.84 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 66 relocations.

Based on the footprint of Option C, 20.0 foot elevation, it was determined that approximately 521 parcels and 134 structures would be impacted. This number includes acquisition of the buffer zone. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction

of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 134 relocations.

Based on the footprint of Option D, 30.0 foot elevation, it was determined that approximately 561 parcels and 144 structures would be impacted. This number includes acquisition of the buffer zone. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 141 relocations.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.8.7 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.8.8 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.8.9 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.8.10 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.8.11 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.8.12 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.8.13 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.8.14 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.8.15 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a

result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 62 relocations in Option A, 66 relocations in Option B, 134 relocations in Option C, and 144 relocations in Option D. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.8.16 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.8.17 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.8.18 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____,

_____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.8.19 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.8.19-1. The real estate estimates at Tables 3.3.8.19-2 through 3.3.8.19-5 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.8.19-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	354	62	$31,458,000
Option B - 30.0	399	66	$34,051,000
Option C - 20.0	521	134	$55,002,000
Option D - 30.0	561	144	$58,603,000

3.3.8.20 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate

Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.8.21 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.8.21-1 through 3.3.8.21-4 shows the CWBS for real estate activities.

3.3.9 Jackson County Ring Levees, Belle Fontaine

Several high density residential and business areas in Jackson County were identified. They are Ocean Springs, Gulf Park, Belle Fontaine, Gautier, and Pascagoula/Moss Point. The subdivision of Belle Fontaine is located just west of Gautier along the gulf coast on Mississippi Sound. The location of the Belle Fontaine ring levee is shown in Figure 3.3.9-1. The northeastern part of the subdivision is near elevation 10-14 feet NAVD88 and very flat. Ground elevations over the southwestern part of the area vary between elevations 16-20 feet NAVD88. These areas are subject to damage from storm surges associated with hurricanes. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A, Option B, Option C and Option D. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88. The top width was assumed 15 ft with side slopes of 1 vertical to 3 horizontal.

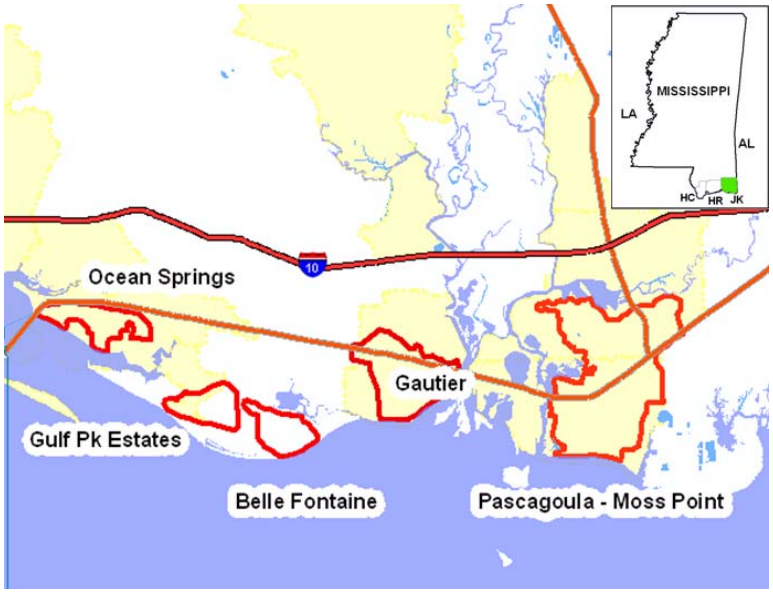

Figure 3.3.9-1. Vicinity Map, Belle Fontaine

3.3.9.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the subdivision of Belle Fontaine along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.9.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.9.3 Option C - Alternate Alignment, Elevation 20.0 ft NAVD88

Option C consists of an earthen levee at elevation 20.0 feet in an alignment slightly different from the alignment for Options A and B. Additionally, the lands that lay between the alignment of Option A and the alternate alignment Option C will be acquired as a buffer zone in this option.

3.3.9.4 Option D - Alternate Alignment, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option C, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option C is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts. As above, the buffer zone lands will be acquired.

3.3.9.5 Project Description

Figure 3.3.9.5-1 shows the location of the proposed project alternatives with the alternate alignment representing Options C and D. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.9.5-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

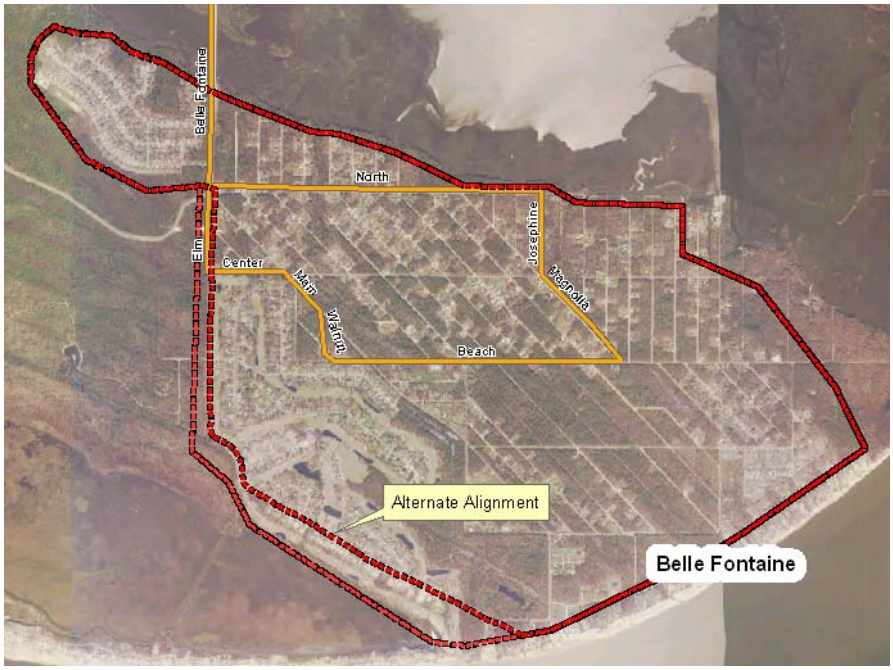

Figure 3.3.9.5-1. Belle Fontaine Ring Levee

Figure 3.3.9.5-2. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed. Pump facilities are required at 7 locations.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used

including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around Belle Fontaine at Option A, elevation 20.0, 10 roadway intersections would have to be accommodated. For this study it was estimated that 5 roller gate structures and 5 swing gate structures would be required. At Option B, elevation 30.0, 13roadway intersections would have to be accommodated, and it was estimated that all 13 would require swing gate structures. At Option C, elevation 20.0, 13 roadway intersections would have to be accommodated and it was estimated that 5 of these would require swing gate structures with the remaining five requiring roller gates of varying heights. At Option D, elevation 30.0, 11 roadway intersections would have to be accommodated and it was estimated that all 11 would require swing gate structures.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.9.6 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Belle Fontaine Ring Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire buffer zone lands, construct an earthen levee, drainage ditches and 7 culvert/pump station facilities.

Based on the footprint of Option A, 20.0 foot elevation, it was determined that approximately 228 parcels and 30 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 30 relocations.

Based on the footprint of Option B, 30.0 foot elevation, it was determined that 297 parcels and 38 structures are impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations would require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 28 relocations.

Based on the footprint of Option C, 20.0 foot elevation, it was determined that 286 parcels and 45 structures would be impacted. This number includes acquisition of the buffer zone lands. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 45 relocations.

Based on the footprint of Option D, 30.0 foot elevation, it was determined that 359 parcels and 54 structures would be impacted. This includes acquisition of the buffer zone lands. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 54 relocations.

Ditches that will be constructed to provide drainage for the interior of the ring levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.9.7 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.9.8 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.9.9 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.9.10 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish

all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.9.11 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.9.12 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.9.13 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.9.14 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.9.15 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic

types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 30 relocations in Option A, 38 relocations in Option B, 45 relocations in Option C, and 54 relocations in Option D. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.9.16 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.9.17 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.9.18 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.9.19 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.9.19-1. The real estate estimates at Tables 3.3.9.19-2 through 3.3.9.19-5 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.9.19-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	228	30	$19,366,000
Option B - 30.0	297	38	$25,774,000
Option C - 20.0	286	45	$26,711,000
Option D - 30.0	359	54	$33,260,000

3.3.9.20 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.9.21 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.9.21-1 through 3.3.9.21-4 shows the CWBS for real estate activities.

3.3.10 Jackson County Ring Levees, Gautier

Several high density residential and business areas in Jackson County were identified. They are Ocean Springs, Gulf Park, Belle Fontaine, Gautier and Pascagoula/Moss Point. Gautier is located on the west side of the Pascagoula River delta at the mouth of the West Pascagoula River at the Mississippi Sound. The location of the Gautier ring levee is shown in Figure 3.3.10-1. Ground elevations over most of the residential and business areas vary between elevations 10-20 feet NAVD88. These areas are subject to damage from storm surges associated with hurricanes. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Option A and Option B. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88. The top width was assumed 15 ft with side slopes of 1 vertical to 3 horizontal.

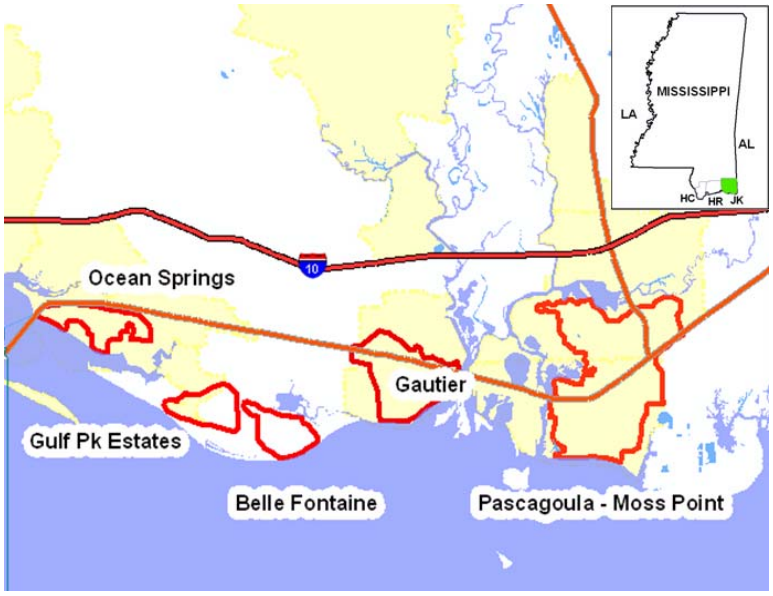

Figure 3.3.10-1. Vicinity Map, Gautier

3.3.10.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the most densely populated areas of Gautier along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal.

3.3.10.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.10.3 Project Description

Figure 3.3.10.3-1 shows the location of the proposed project alternatives. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have tidal gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for manual control in the event the tidal gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.10.3-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

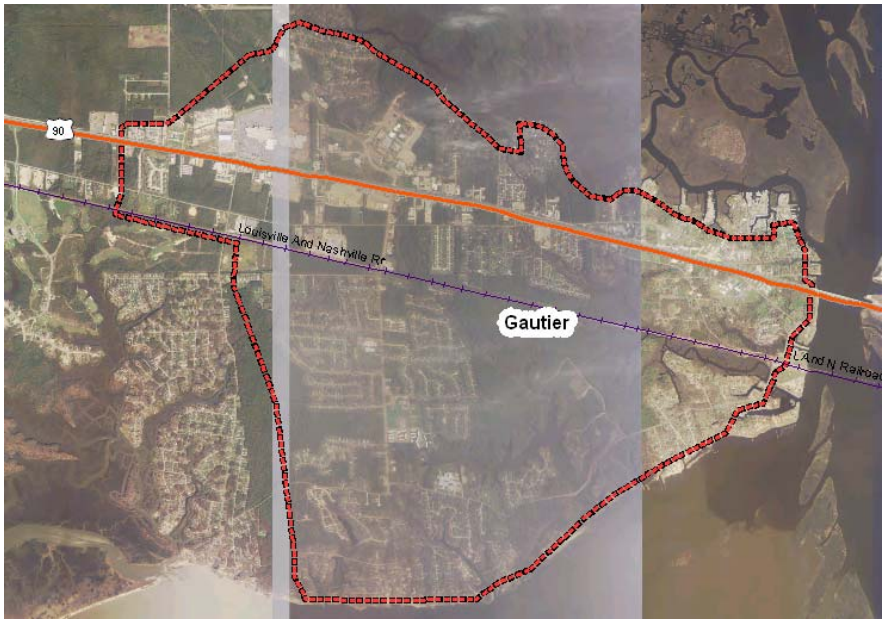

Figure 3.3.10.3-1. Gautier Ring Levee

Figure 3.3.10.3-2. Pump/Culvert/Sub-basin/Boat Access Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study the culverts were configured as cast-in-place reinforced concrete box structures fitted with flap gates to minimize normal backflows and sluice gates to provide closure when needed. Pump facilities are required at 11 locations.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

With the installation of a ring levee around Gautier at Option A, elevation 20.0, 20 roadway intersections would have to be accommodated. For this study it was estimated that 11 roller gate structures and 11 swing gate structures would be required. At Option B, elevation 30.0, 23 roadway intersections would have to be accommodated, and it was estimated that all 23 would require swing gate structures.

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.10.4 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Gautier Ring Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and 11 culvert/pump station facilities.

Based on the footprint of the Option A 20.0 foot elevation, it was determined that approximately 313 parcels and 139 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 11 pump stations will require approximately 0.23 of an acre each for a total of 2.53 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 139 relocations.

Based on the footprint of the Option B 30.0 foot elevation, it was determined that 354 parcels and 161 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 11 pump stations will require approximately 0.23 of an acre each for a total of 2.53 acres. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 161 relocations.

Ditches that will be constructed to provide drainage for the interior of the ring levee are expected to be located within the footprint of the levee. Until final plans and specifications are completed, an assumption is made that the ditches will be constructed on the same lands acquired for construction of the levee. If any additional lands are required, this will be determined during PED.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

In some areas the levee alignment would cross a moderately sized water course where it is apparent that boats currently traverse the area. To allow continued free boat access to areas behind the levee these water courses will be fitted with a scaled down adaptation of the larger rising sector gate structure used for the bay barriers at Biloxi and Bay St. Louis. A small boat access structure is shown at the mouth of multiple basins in the project footprint. Rising sector gates will be provided at these gates allowing shallow draft traffic most of the time. The gates will be closed prior to hurricane storm surge. No additional real estate interest is identified for boat access points as they fall within the footprint of the project and impacted parcels are included in the total that is projected. For those lands required for construction that lay below the mean high water mark, navigation servitude will apply.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report.

Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.10.5 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.10.6 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.10.7 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.10.8 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.10.9 Government Owned Property

There are no known Government owned lands within the proposed project.

3.3.10.10 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.10.11 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.10.12 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.10.13 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 139 relocations in Option A and approximately 161 relocations in Option B. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.3.10.14 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.10.15 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the

NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.10.16 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.10.17 Real Estate Estimate

A summary of the cost for each option is at Table 3.3.10.17-1. The real estate estimates at Table 3.3.10.17-2 and 3.3.10.17-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.10.17-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	313	139	$56,977,000
Option B - 30.0	354	161	$66,585,000

Table 3.3.10.17-2.
LOD3 Jackson County Ring Levee, Gautier - Option A 20.0 Estimate

a. Lands and Improvements/Permits

3.3.10.18 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.10.19 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.10.19-1 and 3.3.10.19-2 shows the CWBS for real estate activities.

3.3.11 Jackson County Ring Levees, Pascagoula/Moss Point

Several high density residential and business areas in Jackson County were identified. They are Ocean Springs, Gulf Park, Belle Fontaine, Gautier and Pascagoula/Moss Point. The cities of Moss Point and Pascagoula lie at the confluence of the Escatawpa and Pascagoula Rivers along the gulf coast on Mississippi Sound as shown on Figure 3.3.11-1. Both the northern part of Moss Point and the southern Part of Pascagoula are very flat. Ground elevations over most of the residential and business areas vary between elevations 10-12 feet NAVD88 in the southern part of the area (Pascagoula) and 14-20 feet NAVD88 in the northern part (Moss Point). These areas are subject to damage from storm surges associated with hurricanes. For purposes of providing protection for future storm events, the construction of an earthen ring levee is evaluated. The options in this study are identified as Options A through H. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88. The top width was assumed 15 ft with side slopes of 1 vertical to 3 horizontal.

3.3.11.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike around the most densely populated areas of Moss Point and Pascagoula along with the internal sub-basins and levee culvert/pump locations. The levee would have an elevation of 20.0 feet with a top width of 15 ft and slopes of 1 vertical to 3 horizontal. This is the basic alignment and is the most extensive, covering the main residential areas in Pascagoula and Moss Point.

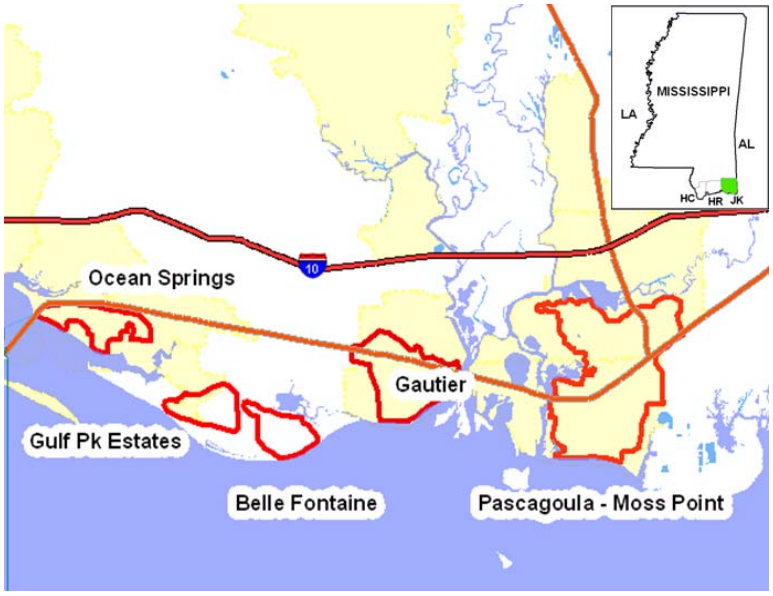

Figure 3.3.11-1. Vicinity Map, Pascagoula/Moss Point

3.3.11.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.3.11.3 Option C - Washington Avenue Alternate Alignment, Elevation 20.0 ft NAVD88

The alignment of the Option C levee is the same as Option A, except that it follows Washington Avenue on the southernmost leg of the levee. Additionally the lands that lay between the alignment of Option A and the alternate alignment Option C will be acquired as buffer zone in this option.

3.3.11.4 Option D - Washington Avenue Alternate Alignment, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option C above. The only difference between the description of this option and preceding description of Option C is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts. As above, the buffer zone lands will be acquired

3.3.11.5 Option E - Moss point Alternate Alignment, Elevation 20.0 ft NAVD88

The alignment of the Option E levee is the same as Option A, except that it follows a modified alignment through Moss Point along higher ground on the north leg of the levee. Additionally the lands that lay between the alignment of Option A and the alternate alignment Option E will be acquired as a buffer zone in this option.

3.3.11.6 Option F - Moss Point Alternate Alignment, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option E above. The only difference between the description of this option and preceding description of Option C is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts. As above, the buffer zone lands will be acquired.

3.3.11.7 Option G - Combined Washington Avenue and Moss Point Alterative Alignments, Elevation 20.0 ft NAVD88

The alignment of the levee is the same as Option A, above, except that is follows the same modified alignment along Washington Ave as for Options C and D on the south, and the modified alignment in Moss Point as for Options E and F along the north leg of the levee. Additionally, the lands that lay between the alignment of Option A and the alternate alignments Option C and Option E will be acquired as buffer zones in this option.

3.3.11.8 Option H - Combined Washington Avenue and Moss Point Alterative Alignments, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option G above. The only difference between the description of this option and preceding description of Option G is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts. As above, the buffer zone lands will be acquired.

3.3.11.9 Project Description

Figure 3.3.11.9-1 shows the location of the proposed project alternatives with the alternate alignments representing Options C-H. As described above, the levee will be an earthen berm constructed either at elevation 20.0 feet or 30.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.3.11.9-2 shows the proposed location of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For this study these were configured as cast-in-place reinforced concrete box

structures fitted with flap gates to minimize normal backflows and sluice gates to provide storm closure when needed. Pump facilities are required at 23-28 locations with variance depending on the option.

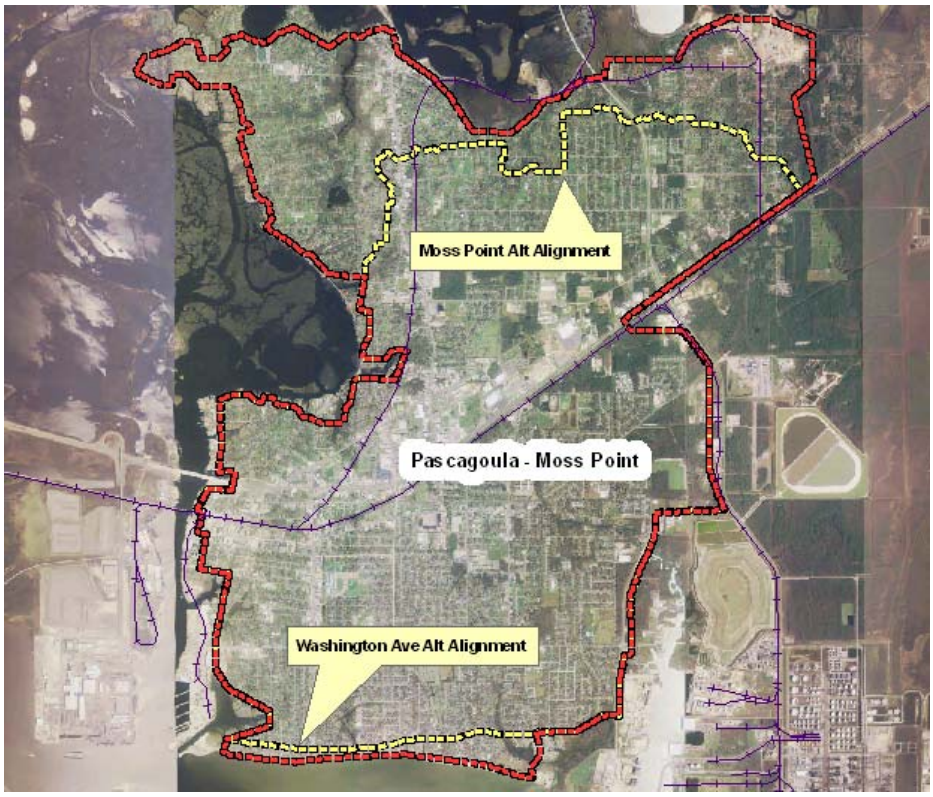

Figure 3.3.11.9-1. Pascagoula/Moss Point Levee

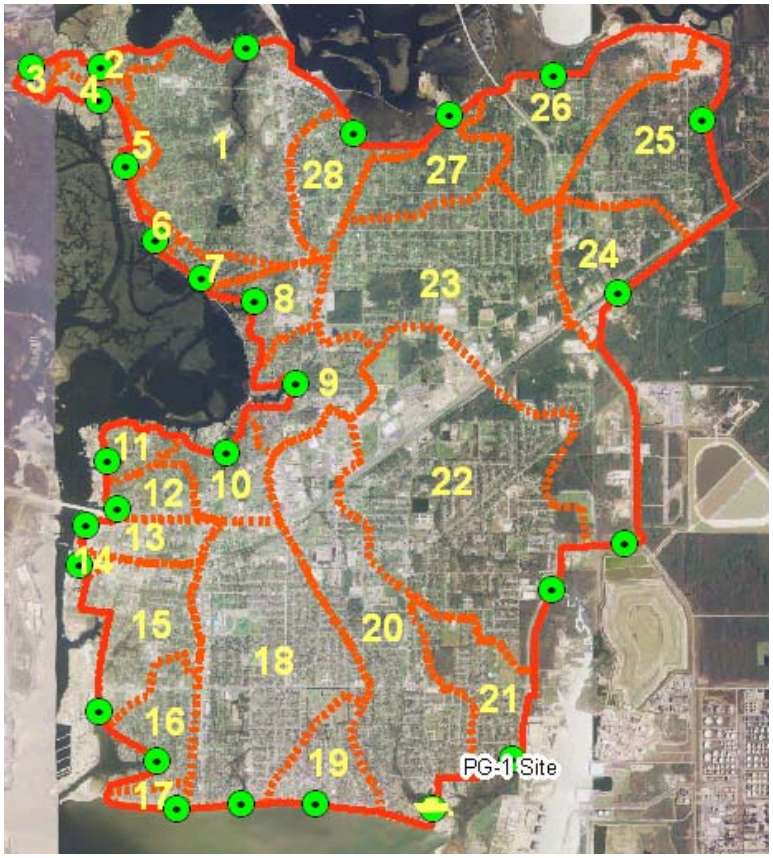

Figure 3.3.11.9-2. Pump/Culvert/Sub-basin/Boat Access Site Locations

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

Table 3.3.11.9-1 summarizes the number of roadway/railway intersections impacted by the various options. The number of roller gate, swing gate and railroad gate structures are listed for each option.

Table 3.3.11.9-1.
Levee and Roadway/Railway Intersections

Option	Roadway/Railway Intersections	Roller Gates	Swing Gates	Railroad Gates
Option A	68	29	35	8
Option B	79	1	73	5
Option C	76	24	108	14
Option D	87	1	180	18
Option E	43	15	56	10
Option F	75		75	14
Option G	48	15	72	10
Option H	79		79	14

Operation and maintenance activities for this project will be required on an annual basis. All pumps and gates will be operated to assure proper working order. Debris and shoaled sediment will be removed. Vegetation on the levees will be cut to facilitate inspection and to prevent roots from causing weak levee locations. Rills will be filled and damaged revetment will be repaired.

3.3.11.10 Real Estate Requirements

Real Estate requirements for Line of Defense 3, Pascagoula/Moss Point Ring Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire buffer zone lands, construct an earthen levee, drainage ditches and 23 - 28 culvert/pump station facilities depending on the option.

Based on the footprint of the Option A, 20.0 foot elevation, it was determined that approximately 1075 parcels and 536 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 28 pump stations will require approximately 0.23 of an acre each for a total of 6.44 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 536 relocations.

Based on the footprint of the Option B, 30.0 foot elevation, it was determined that 1203 parcels and 602 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 28 pump stations will require approximately 0.23 of an acre each for a total of 6.44 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 602 relocations.

Based on the footprint of the Option C, 20.0 foot elevation, it was determined that 1175 parcels and 550 structures would be impacted. Lands for the buffer zone are included in this number. The acreage to be acquired for the levee is unknown. It is known that the 27 pump stations will require approximately 0.23 of an acre each for a total of 6.21 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 550 relocations.

Based on the footprint of the Option D, 30.0 foot elevation, it was determined that 1321 parcels and 623 structures would be impacted. Lands for the buffer zone are included in this number. The acreage to be acquired for the levee is unknown. It is known that the 27 pump stations will require approximately 0.23 of an acre each for a total of 6.21 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 623 relocations.

Based on the footprint of the Option E, 20.0 foot elevation, it was determined that 2964 parcels and 1870 structures would be impacted. Lands for the buffer zone are included in this number. The acreage to be acquired for the levee is unknown. It is known that the 24 pump stations will require approximately 0.23 of an acre each for a total of 5.52 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 1870 relocations.

Based on the footprint of the Option F, 30.0 foot elevation, it was determined that 3076 parcels and 1926 structures would be impacted. Lands for the buffer zone are included in this number. The acreage to be acquired for the levee is unknown. It is known that the 24 pump stations will require approximately 0.23 of an acre each for a total of 5.52 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 1926 relocations.

Based on the footprint of the Option G 20.0 foot elevation, it was determined that 3138 parcels and 1939 structures would be impacted. Lands for the buffer zone are included in this number. The acreage to be acquired for the levee is unknown. It is known that the 23 pump stations will require approximately 0.23 of an acre each for a total of 5.29 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 1939 relocations.

Based on the footprint of the Option H, 30.0 foot elevation, it was determined that 3253 parcels and 1994 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 23 pump stations will require approximately 0.23 of an acre each for a total of 5.29 acres. Lands required for the buffer zone and for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 1994 relocations. Table 3.3.11.10-1 below summarizes the real estate requirements for the various alternatives.

Table 3.3.11.10-1.
Real Estate Requirements - LOD3 Pascagoula/Moss Point Alternatives

Option	Impacted Parcels	Impacted Structures	# Pump Stations/AC	Relocations
Option A	1,075	536	28 6.44 AC	536
Option B	1,203	602	28 6.44 AC	602
Option C	1,175	550	27 6.21 AC	550
Option D	1,321	623	27 6.21 AC	623
Option E	2,964	1,870	24 5.52 AC	1870
Option F	3,076	1,926	24 5.52 AC	1926
Option G	3,138	1,939	23 5.29 AC	1939
Option H	3,253	1,994	23 5.29 AC	1994

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

In some areas the levee alignment would cross a moderately sized water course where it is apparent that boats currently traverse the area. To allow continued free boat access to areas behind the levee these water courses will be fitted with a scaled down adaptation of the larger rising sector gate structure used for the bay barriers at Biloxi and Bay St. Louis. A small boat access structure is shown at the mouth of one basin in the project footprint. Rising sector gates will be provided at this gate allowing shallow draft traffic most of the time. The gate will be closed prior to hurricane storm surge. No additional real estate interest is identified for boat access points as they fall within the footprint of the project and impacted parcels are included in the total that is projected. For those lands required for construction that lay below the mean high water mark, navigation servitude will apply.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.3.11.11 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.3.11.12 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.3.11.13 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.3.11.14 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.3.11.15 Government Owned Property

One (1) Government owned parcel is within the footprint of the project. In viewing the footprint, it appears that approximately 30% of the parcel will be impacted by construction of the levee. Land value is listed as $131,090 and improvement value is listed as $427,020. Ownership is listed in public records as US Govt (Pasc Fishery Lab). Specific impacts to this particular parcel and/or structure will be determined during PED.

3.3.11.16 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.3.11.17 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.3.11.18 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.3.11.19 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

Table 3.3.11.19-1 shows the number of expected relocations for each Option. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

Table 3.3.11.19-1.
PL 91-646 - Relocation Assistance

Option	Number of Relocations
Option A	536
Option B	602
Option C	550
Option D	623
Option E	1870
Option F	1926
Option G	1939
Option H	1994

3.3.11.20 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles

that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.3.11.21 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.3.11.22 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and for drainage ditches constructed outside the footprint of the levee, fee or the Drainage Ditch Easement will be used as appropriate. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.3.11.23 Real Estate Estimate

A summary of cost for each option is at Table 3.3.11.23-1. The real estate estimates at Tables 3.3.11.23-2 through 3.3.11.23-9 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.3.11.23-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	1,075	536	$237,004,000
Option B - 30.0	1,203	602	$256,517,000
Option C - 20.0	1,175	550	$278,147,000
Option D - 30.0	1,321	623	$297,899,000
Option E - 20.0	2,964	1,870	$520,145,000
Option F - 30.0	3,076	1,926	$533,059,000
Option G - 20.0	3,138	1,939	$574,040,000
Option H - 30.0	3,253	1,994	$584,742,000

3.3.11.24 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate

Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.3.11.25 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.3.11.25-1 through 3.3.11.25-8 shows the CWBS for real estate activities.

3.4 Line of Defense 4 - Inland Barrier and Surge Gates

To preserve the shoreline environment as much as possible, a 4th line of defense for very large storms is envisioned that would be inland from the coast. This line of defense would be the highest line and could contain a larger storm surge up to that associated with a "Maximum Possible Intensity" (MPI) hurricane. Storms that will be modeled against this line will vary from a Camille type storm up to the MPI. This alignment would follow the same path as the railway that crosses the state near the coast but not cross either the Pearl River in Hancock County to the west or the Pascagoula River in Jackson County to the east. In Harrison County, this pathway is through heavily populated and commercial zones. The first major watershed divide west of the Pascagoula River was selected to turn the barrier north and extend it to a location beyond the extent of the storm surge associated with a MPI event. Similarly to the west in Hancock County, LOD-4 follows the railway to a watershed divide that is located east of the Pearl River where it follows the divide north to the MPI line. Both of these northward extensions will cross the path of Interstate 10 and may dictate some modifications to the highway depending on the selected top elevation of the line.

In order to protect much of the developed areas around Biloxi and St. Louis Bays, LOD-4 would have to include a structural surge barrier that would also cross the mouth of these bays. These surge barriers, when closed, would prevent storm surge from moving in through the inlets of the bays. The structural barriers across the bays could be similar to designs used in Europe for storm surge protection.

LOD-4 could also be designed to have roadways, even major highways on top if desired. This line would be the highest defense, but would not protect structures seaward from the larger storms that might overtop Line 3. All facilities seaward of Line 4 would be prone to flooding in a large storm, so flood-proofing would be necessary in this zone. As described prior, this barrier would extend from high ground east of the Pearl River to high ground west of the Pascagoula River for a distance of approximately 57 miles. It would not cross either of these river systems.

3.4.1 Hancock County Inland Barrier

Several high density residential and business areas are located in Hancock County. These are subject to damage from storm surges associated with hurricanes. Earthen levees were evaluated for protection of these areas. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88 and 40 ft NAVD88. The top width was assumed 15 ft with side-slopes of 1 vertical to 3 horizontal. These alternatives are Identified as Option A, Option B and Option C. Storm surge gates across St Louis Bay are also included to prevent flooding from hurricanes.

Hancock County is located on the west side of the Mississippi coast of Mississippi Sound as shown in Figure 3.4.1-1. The main residential and business areas are at Bay St Louis and Waveland. Ground elevations over the areas behind the levee vary between elevations 10-20 ft NAVD88 at low areas to as low as 5 ft NAVD88 in the Shoreline Park area. The area drains to the south along the coast to Mississippi Sound, to the north and east to St Louis Bay, and on the far west to Pearl River. The location of the levee in Hancock County is parallel to the CSX Railroad and the coast and turns northward across I-10 to tie into the corresponding elevation.

Figure 3.4.1-1. Vicinity Map Hancock County, MS

3.4.1.1 Option A - Elevation 20.0 ft NAVD88

This option consists of an earthen dike across the high ground of the county along with the internal sub-basins and levee culvert/pump locations. The levee would have a top width of 15 ft and slopes of 1 vertical to 3 horizontal. The levee is located mostly along high ground so ponding at the levee would be minimal. However, some ditching for drainage would be required on the outside of the levee.

3.4.1.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.1.3 Option C - Elevation 40.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 40.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.1.4 Project Description

Figures 3.4.1.4-1 through 3.4.1.4-3 show the location of the proposed project alternatives. As described above, the inland barrier will be an earthen levee constructed either at elevation 20.0 feet, 30.0 or 40.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figures 3.4.1.4-4 through 3.4.1.4-6 show the proposed locations of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas.

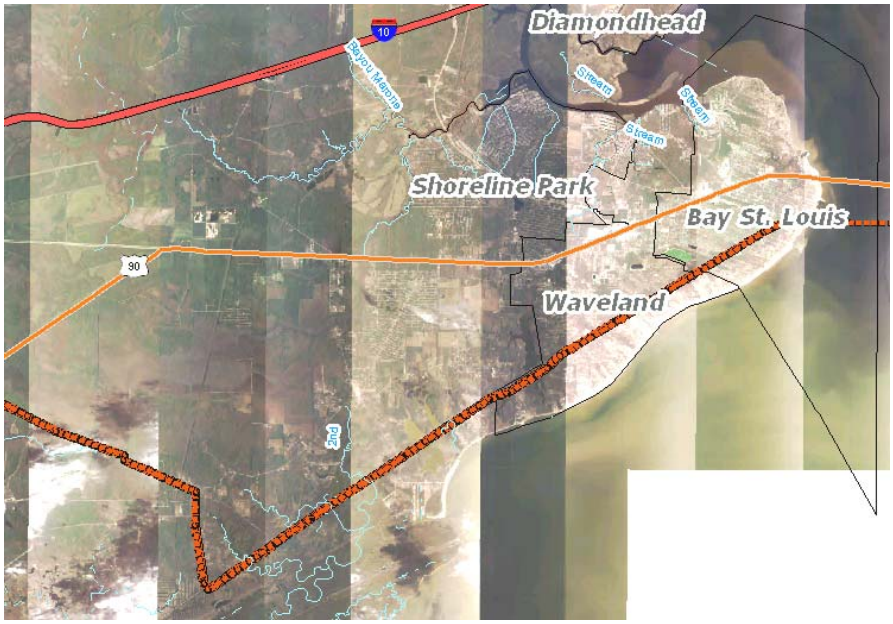

Figure 3.4.1.4-1. Hancock County Inland Barrier

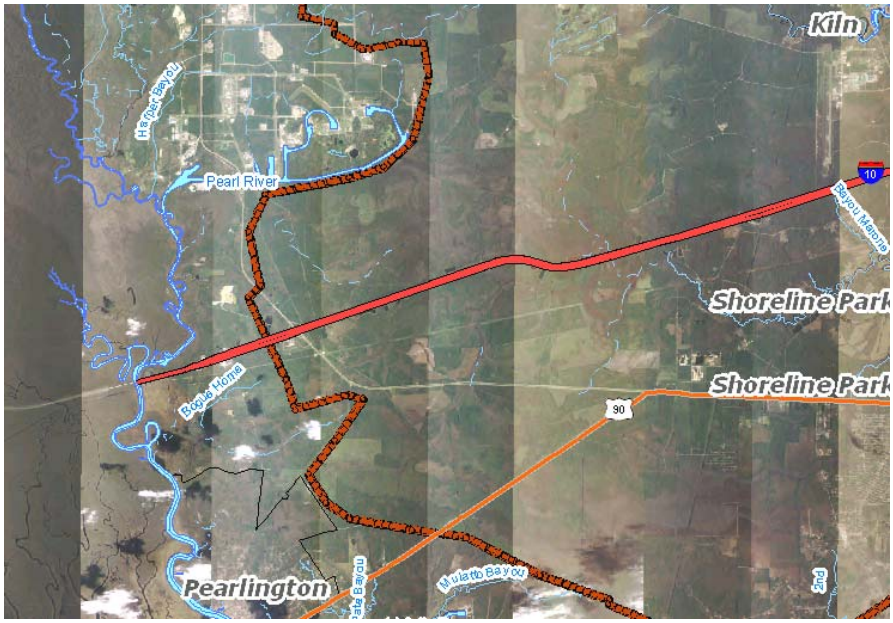

Figure 3.4.1.4-2. Hancock County Inland Barrier

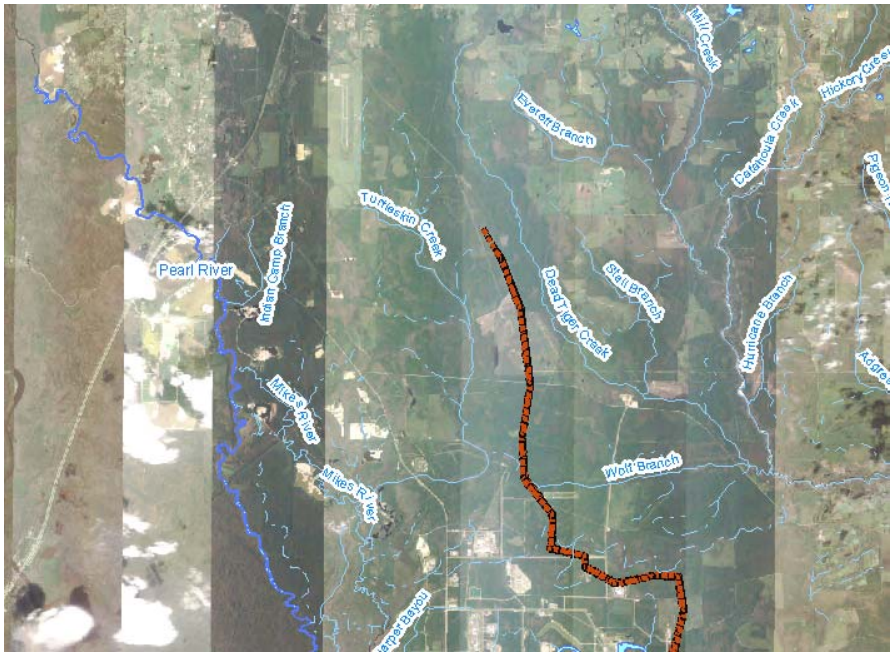

Figure 3.4.1.4-3. Hancock County Inland Barrier

Figure 3.4.1.4-4. Pump/Culvert/Sub-basins/Boat Access Site Locations

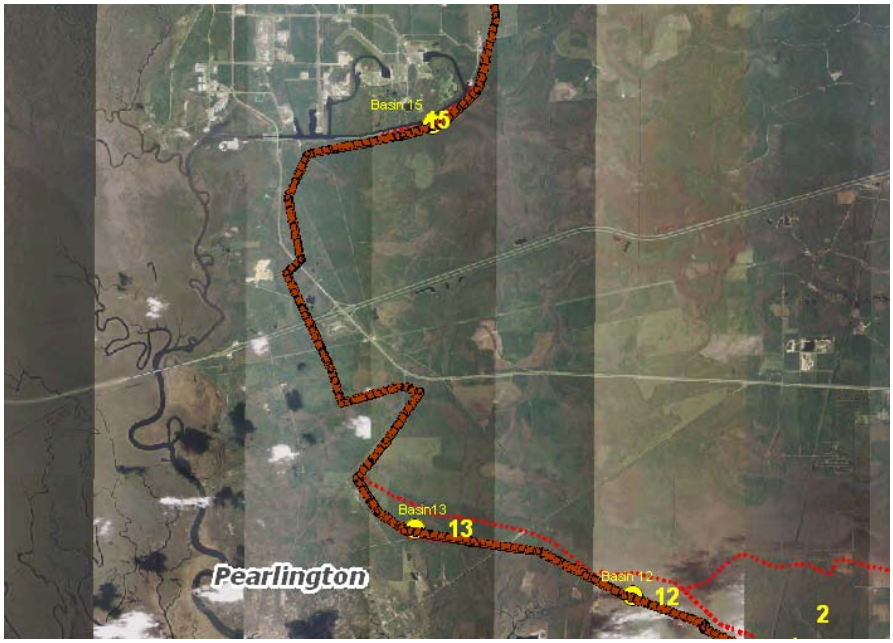

Figure 3.4.1.4-5. Pump/Culvert/Sub-basin Site Locations

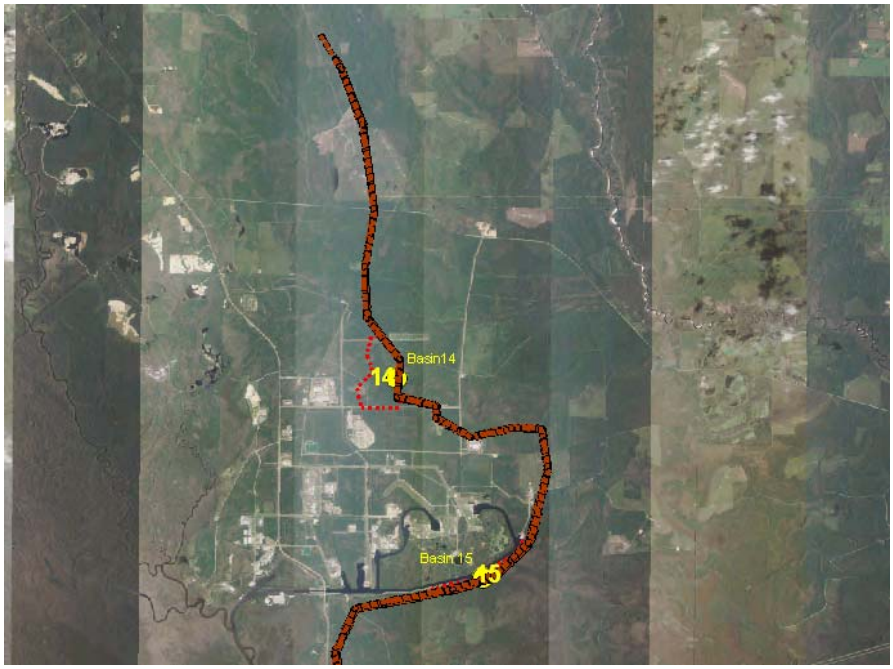

Figure 3.4.1.4-6. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For Options A, B, and C, drainage features would be required at 16 locations ranging from 20-inch diameter reinforced concrete pipe to reinforced concrete box culverts having 11 water passages, each measuring 12' wide by 4' high. Each water passage would be fitted with both a flap gate at the outlet end and a sluice gate placed near the center of the culvert with a vertical operator stem extending through an access shaft to the top of levee elevation.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee. With the installation of a ring levee at Option A, elevation 20.0, 14 roadway/railroad intersections would have to be accommodated. For this study it was estimated that 4 roller gate structures and 6 swing gate structures would be required. In addition, 4 railroad gate structures would be required. At Option B, elevation 30.0, 31 roadway/railroad intersections would have to be accommodated, and it was estimated that 9 roller gate structures and 18 swing gate structures would be required. In addition, 4 railroad gate structures would be required. At Option C, elevation 40.0, 40 roadway/railroad intersections would have to be accommodated, and it was estimated that all 36 of the highway crossings would require swing gates. In addition, 4 railroad gate structures would be required.

The features that require periodic operations will be the exercising of the pumps and emergency generators at the various pump stations, the testing of the gate structures at the various road crossings, grass cutting of the levee slopes and toe areas and the filling of rilled areas within the

embankment due to surface erosion. Scheduled maintenance should include periodic greasing of all gears and coupled joints, maintaining any battery backup systems, and replacement of standby fuel supplies.

3.4.1.5 Real Estate Requirements

Real Estate requirements for Line of Defense 4, Hancock County Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and 3 pump station facilities.

Based on the footprint of the Option A, 20.0 foot elevation, it was determined that approximately 426 parcels and 160 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 3 pump stations will require approximately 0.23 of an acre each for a total of 0.69 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 160 relocations.

Based on the footprint of the Option B, 30.0 foot elevation, it was determined that 484 parcels and 186 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 3 pump stations will require approximately 0.23 of an acre each for a total of 0.69 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 186 relocations.

Based on the footprint of the Option C, 40.0 foot elevation, it was determined that 537 parcels and 209 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 3 pump stations will require approximately 0.23 of an acre each for a total of 0.69 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 209 relocations.

Any modifications to the roadways and utilities will most probably need to be accomplished thorough a relocation contract. This will be further investigated and confirmed during PED.

Footprints for drainage ditches are not available at time of this report. However, from the figures it appears that acquisition of additional lands for drainage ditches outside the footprint of the levee will be minimal. Until final plans and specifications are completed, land requirements for drainage ditches are assumed to be covered by contingency. This additional requirement will be determined during PED.

In some areas the levee alignment would cross a moderately sized water course where it is apparent that boats currently traverse the area. To allow continued free boat access to areas behind the levee these water courses will be fitted with a scaled down adaptation of the larger rising sector gate structure used for the bay barriers at Biloxi and Bay St. Louis. A small boat access structure is shown at the mouth of multiple basins in the project footprint. Rising sector gates will be provided at these gates allowing shallow draft traffic most of the time. The gates will be closed prior to hurricane storm surge. No additional real estate interest is identified for boat access points as they fall within the footprint of the project and impacted parcels are included in the total that is projected. For those lands required for construction that lay below the mean high water mark, navigation servitude will apply.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with

the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.4.1.6 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.4.1.7 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.4.1.8 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.4.1.9 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the

non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.4.1.10 Government Owned Property

There are 18-25 Government owned parcels within the footprint of the project that will be impacted depending on the option recommended for construction. In viewing the footprint, it is noted that the levee will run through the middle of many of these parcels. However, others may have only minimal impact. These lands are in the vicinity of the John C. Stennis Space Center, or within lands shown as NASA Restricted Area on a state map. Land and structure values are not listed in the public records. Ownership is listed in public records as USA or United States of America. Specific impacts to Government owned lands will be determined during PED.

3.4.1.11 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.4.1.12 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.4.1.13 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.4.1.14 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 160 relocations in Option A, approximately 186 relocations in Option B, and approximately 209 relocations in Option C. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.4.1.15 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area

to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.4.1.16 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.4.1.17 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used for construction of any drainage ditches outside the footprint of the levee as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement

hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.4.1.18 Real Estate Estimate

A summary of the cost for each option is at Table 3.4.1.18-1. The real estate estimates at Tables 3.4.1.18-2 through 3.4.1.18-3 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

3.4.1.19 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L 91-646. There are a number of factors pertaining to relocations that can impact the project both

in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

Costs for easements for drainage ditches are not included in this report as the requirement was identified late in the study, and a footprint for the drainage ditches is not provided At this time it is believed that the cost will be minor and that it will have minimal impacts to the overall project costs. A determination of additional land requirements for drainage ditches will be made during PED.

3.4.1.20 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.4.1.20-1 through 3.4.1.20-3 shows the CWBS for real estate activities.

3.4.2 St. Louis Bay Surge Barrier

In order to protect the properties surrounding Saint Louis Bay and along the lower portions of the various rivers and streams flowing into the bay, a barrier would be required at some point to block storm waters during major storm events. A search of other similar facilities constructed world wide revealed that the structure model best satisfying both the engineering and socio-ecological necessities of this site was that used for the Thames River Barrier in London, UK. The structure tentatively investigated for incorporation into this work was patterned after the Thames River Barrier with certain minor modifications to adapt to the site and environment specific conditions.

A photograph of the Thames River Gates is at Figure 3.4.2-1. The St. Louis Bay watershed covers approximately 654 square miles and is comprised of six sub-basins that stretch across the Mississippi counties of Harrison, Hancock, Stone and Pearl River.

Figure 3.4.2-1. Thames River Gates, London, UK

In the event of an imminent hurricane, the gates St Louis Bay would be closed, and flow from the rivers feeding these bays, as well as local runoff would pond behind the gates. The tentative location of the barrier chosen for this study is shown below in Figure 3.4.2-2. The alternatives for this proposed measure are identified as Option A, Option B and Option C.

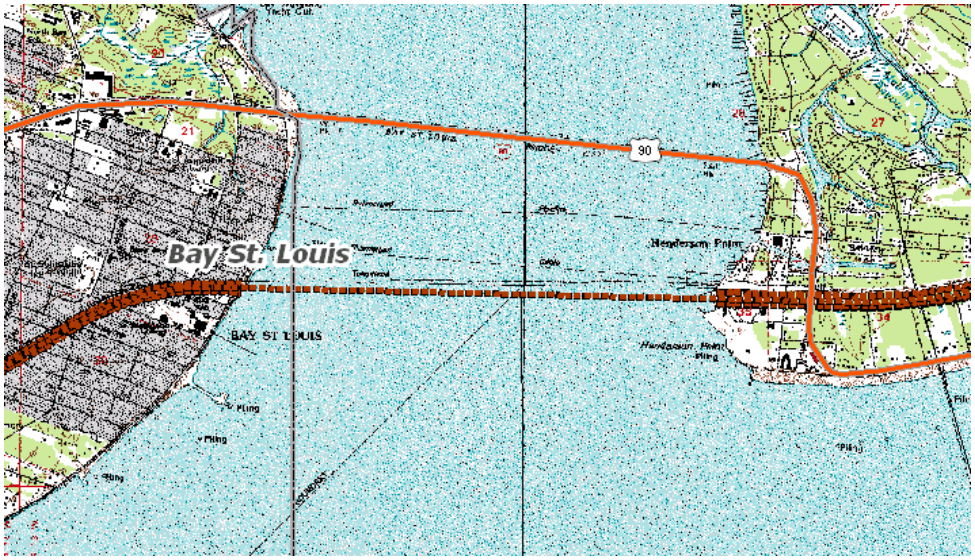

Figure 3.4.2-2. St Louis Bay Surge Barrier Location

3.4.2.1 Option A - Elevation 20.0 ft NAVD88

Option A is the design and construction of a rising sector gate in the St. Louis Bay creating a barrier to elevation 20.0.

3.4.2.2 Option B - Elevation 30.0 ft NAVD88

Option B is the design and construction of a rising sector gate in the St. Louis Bay creating a barrier to elevation 30.0.

3.4.2.3 Option C - Elevation 40.0 ft NAVD88

Option C is the design and construction of a rising sector gate in the St. Louis Bay creating a barrier to elevation 40.0.

3.4.2.4 Project Description

The alignment for the barrier structure would run parallel with and south of the Railroad Bridge crossing Saint Louis Bay. This would approximate the shortest route across the inlet leading form the Mississippi Sound into the bay. As the layout of the barrier was developed it became apparent that, because of the excavation required, a significant amount of separation would be required between the railroad bridge and the ultimate location of the structures included in the barrier. For this study the centerline of the barrier was positioned approximately 260 feet from the center of the railroad bridge. This was left unaltered for all protection levels. The entire barrier would be approximately 10,320 feet in length from water's edge to water's edge, and would consist of rock fill levees extending from the overland levee at each bank for some distance into the bay and enveloping the mass concrete non-overflow wall sections leading to each end of the gated structure.

The points at which the barrier would come ashore in Harrison County on the east and Hancock County on the west, are in urban areas with extensive residential and commercial development. Several structures would need to be relocated and it is uncertain the extent to which existing utilities might have to be relocated to clear the way for this facility.

Structurally, the Barrier as configured for this study would consist of a series of 38 large stainless steel clad, structural steel framed gates called rising sector gates. Each of these would be supported on reinforced concrete piers resting on large continuous concrete sills with pile foundations. The tentative layout used to estimate the scope of the structure was configured having gates 132 feet long mounted on 28-foot wide piers. The number of gates was determined by the extent of water having depth sufficient to support their operation. To facilitate as nearly as possible the normal ebb and flow of tide waters through the barrier, the concrete connector wall and rock fill portions of the barrier either side of the gated structure would be fitted with a series of closely spaced low level gated culverts. The gate and pier heights were varied to accommodate the "level of protection" under consideration. The three elevations selected for this study were 20, 30, and 40 NAVD88. In each instance the gate heights were set to match the protection level elevations with pier heights set approximately 3 feet higher to provide minor wave clearance for protection of operating equipment. Atop each pier an operating machinery block would be mounted to house the operating equipment. Operating and utility access would be provided through two continuous tunnels passing through the sill section and the rock fill, to operating facilities located on each bank.

In order to assure proper functioning of the facilities once they are placed in service a program of Operations and Maintenance would be developed by the U.S. Army Corps of Engineers, in conjunction and cooperation with the affected state and local entities. This O & M Plan would address specific responsibilities as to daily operation of the facilities, the periodic testing and

maintenance of the operating machinery, maintenance of specified stocks of replacement parts, security of the facilities, and maintenance of any buildings and grounds associated with the operation and maintenance of the facilities. As presently envisioned, this O & M responsibility would remain under control of the U.S. Army Corps of Engineers and would be administered under its Operations mission.

3.4.2.5 Real Estate Requirements

Real Estate requirements for Line of Defense 4, St. Louis Bay Surge Barrier include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct, rock levees and an elevated gate barrier in St. Louis Bay with operating facilities located on each landward bank of the barrier. The rock levees on either side of the gates will tie into the LOD4 inland barrier. There will be 2 operating facilities, one located in Hancock County and the other in Harrison County. Each site will be comprised of approximately 5 acres and these will be acquired in fee. The real estate cost estimate will be the same for each option as they all have the same requirements.

For those lands required for construction that lay below the mean high water mark, navigation servitude will apply. Navigation servitude is the dominant right of the Government under the Commerce Clause of the U.S. Constitution (U.S. CONST. Art.I,§8,cl.3) to use, control and regulate the navigable waters of the United States and the submerged lands hereunder for various commerce-related purposes including navigation and flood control. In tidal areas, the servitude extends to all lands below the, mean high water mark. In non-tidal areas, the servitude extends to all lands within the bed and banks of a navigable stream that lie below the ordinary high water mark. The determination of the availability of the navigation servitude should be made on a case by case basis and consists of a two -step process. First the government must determine whether the project serves a purpose that has a nexus to navigation. Purposes recognized by the courts to have the nexus include navigation, flood control and hydroelectric power. If determined that such a nexus exists, then the second step is to determine whether the land at issue is located below the mean or ordinary high water mark of a navigable watercourse. As a general rule, the Government does not acquire interests in real property that it already possesses or over which its use or control is or can be legally exercised. Therefore, if the navigation servitude is found to be available as a result of application of the process described in subparagraph b of this paragraph, then the Government will generally exercise its rights hereunder and, to the extent of such rights, will not acquire a real property interest in the land to which the navigation servitude applies. Generally, it is the policy of the U.S. Army Corps of Engineers (USACE) to utilize the navigation servitude in all situations where available, for cost shared and full Federal projects. The determination of availability will be made during PED.

3.4.2.6 Utility/Facility Relocation

It is probable that there will be some utility/facility relocations for this plan. Specific requirements are unknown at this time but will be defined during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.4.2.7 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.4.2.8 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.4.2.9 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.4.2.10 Government Owned Property

There are no known Government owned lands within the proposed project.

3.4.2.11 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.4.2.12 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.4.2.13 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.4.2.14 Public Law 91-646, Relocation Assistance Benefits

No relocations are expected with this alternative.

3.4.2.15 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.4.2.16 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.4.2.17 Estates for Proposed Project

All lands required for the operating facilities will either be acquired in Fee Simple or are available under navigation servitude.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.4.2.18 Real Estate Estimate

The real estate estimate at Table 3.4.2.18-1 includes the land cost for acquisition of land, permits, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a temporary work area. The requirement, if any, for a temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.4.2.18-1.
LOD4 St. Louis Bay Surge Barrier - Option A, B or C Estimate

a. Lands and Improvements/Permits

	Rounded			**1,110,000**

3.4.2.19 Summary of Potential Real Estate Issues

It is expected that navigation servitude will be exercised to construct the surge barrier in St. Louis Bay. This determination will be made during PED

It is probable that there will be some utility/facility relocations for this plan. Specific requirements are unknown at this time but will be defined during PED.

The requirement for temporary work areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements.

Should temporary work areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with temporary work areas and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

3.4.2.20 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.4.2.20-1 shows the CWBS for real estate activities.

	Rounded			**1,110,000**

3.4.3 Harrison County Inland Barrier

Harrison County is located along the coast of Mississippi Sound with Hancock County to the west and Jackson County to the east. In Harrison County, ground elevations over most of the residential and business areas vary between elevation 8-12 ft NAVD88 on the coast and rising within 1000 ft to elevation 30-36 along a ridge parallel to the coast line, then decreasing to the north.

Residential and business areas along the coast in Harrison County are susceptible to damage from storm surges associated with hurricanes. Earthen levees were evaluated for protection of these areas. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88 and 40 ft NAVD88. The top width was assumed 15 ft with side-slopes of 1 vertical to 3 horizontal. The location of the proposed inland barrier in Harrison County is shown in Figure 3.4.3-1 extending from Biloxi Bay to Pass Christian approximately 1000 - 3000 feet north of, and parallel to, the shoreline. This alignment is evaluated in Options A through E. For Options F through J, an alternate alignment is evaluated.

This alternate alignment extends from Biloxi Bay to Menge Avenue, thence northward along Menge Avenue to high ground.

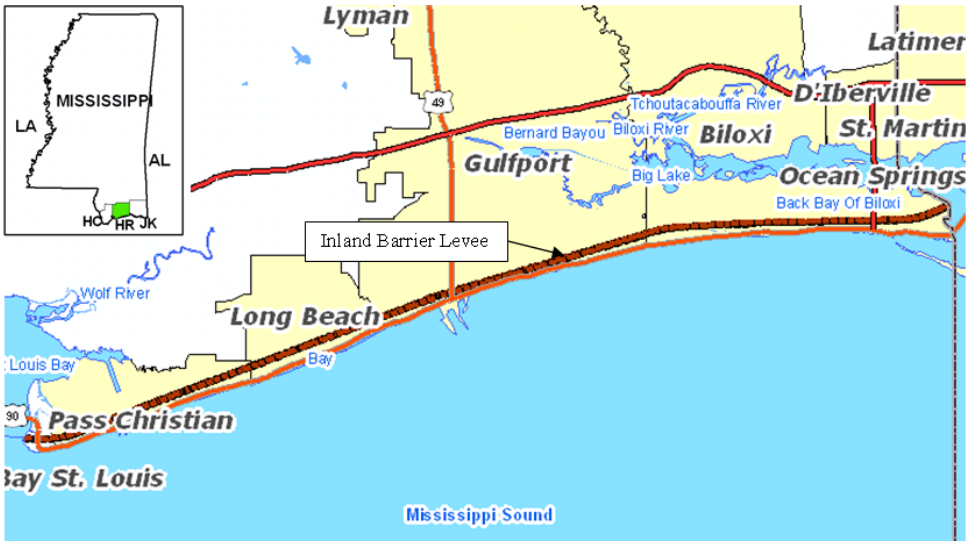

Figure 3.4.3-1. Vicinity Map Harrison County, MS

3.4.3.1 Option A - Elevation 20.0 ft NAVD88

This option consists of constructing a levee to elevation 20 ft NAVD88 along the coast of Harrison County along with the internal sub-basins and levee culvert/pump locations. These sites will be ditched along the levee to drain to St. Louis Bay and Biloxi Bay.

3.4.3.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.3.3 Option C - Elevation 40.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 40.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.3.4 Option D - Levee for Roadway, Elevation 20.0 ft NAVD88

The alignment of the levee is the same as Option A, above. The difference between this option and Option A is that the width of the top of the levee in Harrison County is 75 ft for Option D and 15 ft for Option A. This added width will allow Highway 90 to be relocated along the top of the levee.

3.4.3.5 Option E - Levee for Roadway, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as option A, above. The difference between this option and Option A is that the width of the top of the levee in Harrison County is 75 ft for Option A. In addition, the height of the levee is at 30 ft NAVD88 for Option E and 20 ft NAVD88 for Option A. This added width will allow Highway 90 to be relocated along the top of the levee.

3.4.3.6 Option F - Menge Avenue Alternate Route, Elevation 20.0 ft NAVD88

The alignment of the levee is the same as Option A on the east side of Harrison County but extends to the north along Menge Avenue instead of continuing westward.

3.4.3.7 Option G - Menge Avenue Alternate Route, Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option F. The primary difference between this option and Option F is the height of the levee. Option F levee height is elevation 20 ft NAVD88 and Option G levee height is elevation 30 ft NAVD88.

3.4.3.8 Option H - Menge Avenue Alternate Route, Elevation 40.0 ft NAVD88

The alignment of the levee is the same as Option F. The primary difference between this option and Option F is the height of the levee. Option F levee height is elevation 20ft NAVD88 and Option H levee height is elevation 40 ft NAVD88.

3.4.3.9 Option I - Levee for Roadway with Menge Avenue Alternate, Route Elevation 20.0 ft NAVD88

The alignment of the levee is the same as Option F. The primary difference between this option and Option F is the top width of the east-west leg of the levee (Biloxi Bay to Menge Avenue). The east-west leg of Option F barrier top width is 15 ft and the east-west leg of Option I barrier top width is 75 ft. This will allow Highway 90 to be relocated along the top of the levee.

3.4.3.10 Option J - Levee for Roadway with Menge Avenue Alternate, Route Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option F. The primary difference between this option and Option F is the top width of the east-west leg of the levee (Biloxi Bay to Menge Avenue). The east-west leg of Option F barrier top width is 15ft and the east-west leg of Option J barrier top width is 75 ft. This will allow Highway 90 to be relocated along the top of the levee. In addition, the height of this Option J is at elevation 30 ft NAVD88.

3.4.3.11 Project Description

The location of the proposed project is shown above in Figure 3.4.3-1. As described, the levee will be an earthen levee constructed either at elevation 20.0 feet, 30.0 or 40.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figures 3.4.3.11-1 through 3.4.3.11-3 show the

proposed locations of the pump/culvert sites for Options A through E. Figures 3.4.3.11-4 through 3.4.3.11-6 show the Menge Avenue alternate route. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas. In order to prevent hurricane surges from circumventing the levee, surge barrier gates would be constructed across both Biloxi Bay and St. Louis Bay. In the event of an imminent hurricane, the gates across the Back Bay of Biloxi and St. Louis Bay would be closed, and flow from the rivers feeding these bays, as well as local runoff would pond behind the gates.

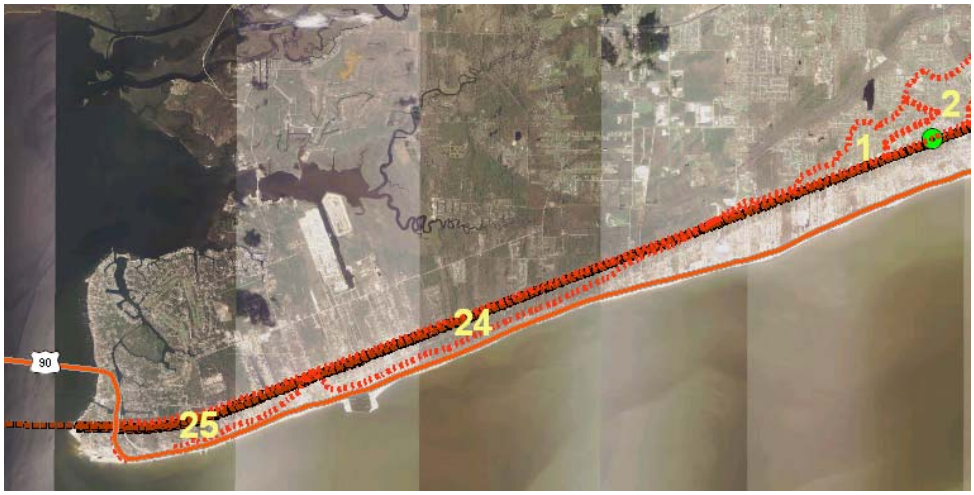

Figure 3.4.3.11-1. Pump/Culvert/Sub-basin Site Locations, Options A-E

Figure 3.4.3.11-2. Pump/Culvert/Sub-basin Site Locations, Options A-E

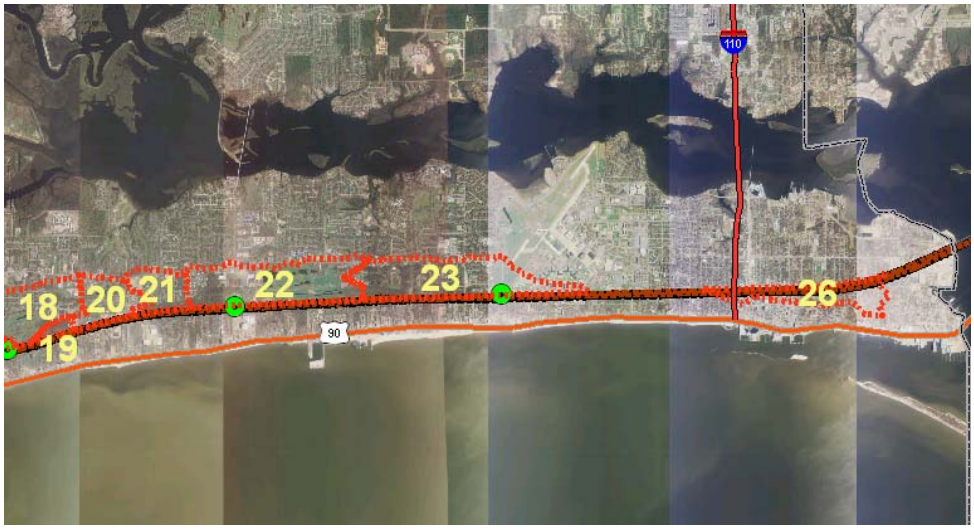

Figure 3.4.3.11-3. Pump/Culvert/Sub-basin Site Locations, Options A-E

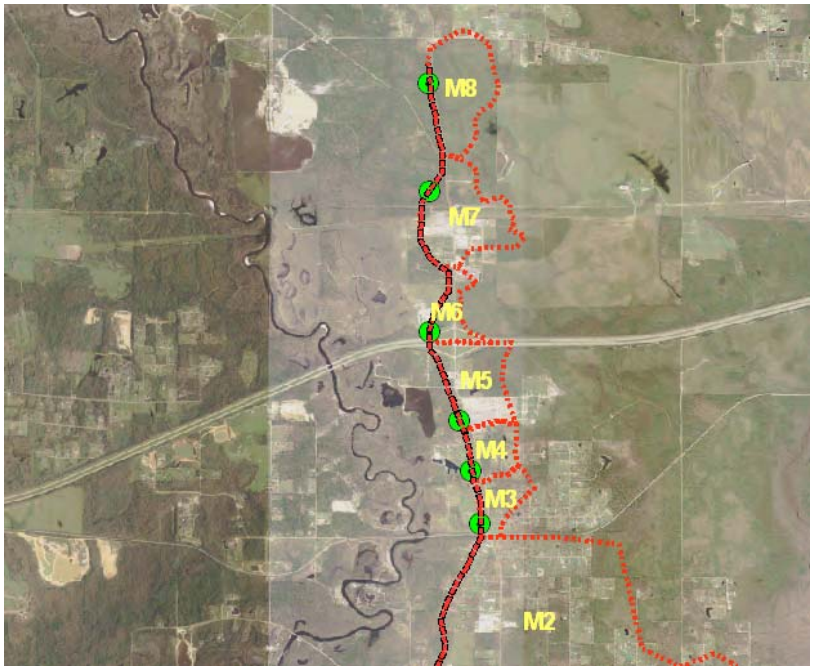

Figure 3.4.3.11-4. Menge Avenue Alternate Route, Pump/Culvert, Sub-basin Site Locations, Options F-J

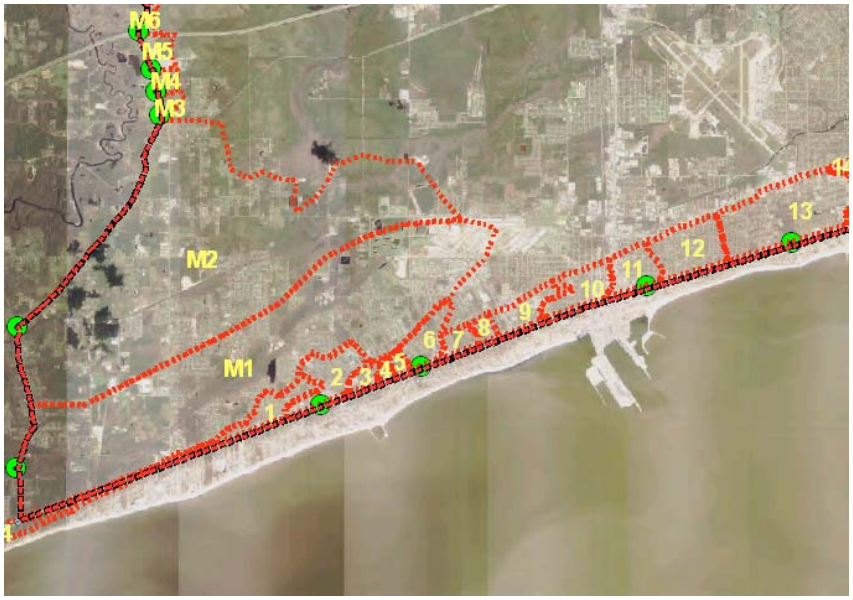

Figure 3.4.3.11-5. Menge Avenue Alternate Route, Pump/Culvert, Sub-basin Site Locations, Options F-J

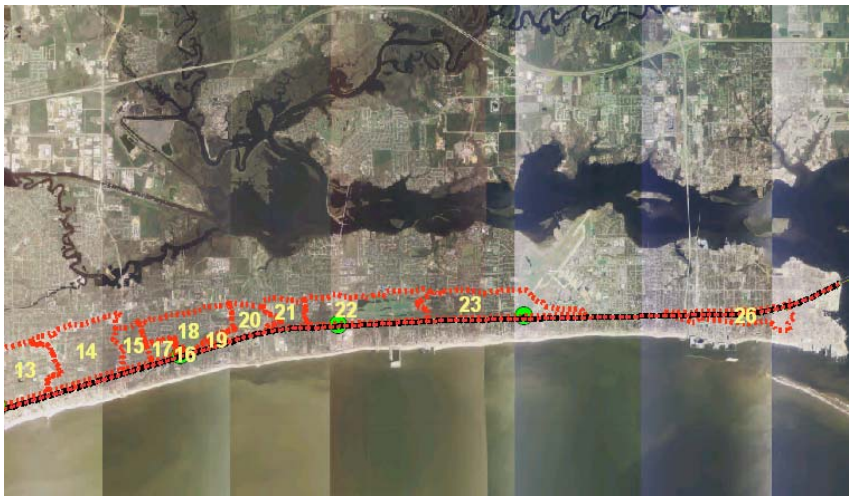

Figure 3.4.3.11-6. Menge Avenue Alternate Route, Pump/Culvert, Sub-basin Site Locations, Options F-J

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be

armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. Pump facilities would be required at 7 - 14 locations varying with the option.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee.

Table 3.4.3.11-1 summarizes the number of roadway/railway intersections impacted by the various options. The number of roller gate, swing gate and railroad gate structures are listed for each option.

Table 3.4.3.11-1.
Levee and Roadway/Railway Intersections

Option	Roadway/Railway Intersections	Roller Gates	Swing Gates	Railroad Gates
Option A	45	18	27	
Option B	30	158	78	2
Option C	161	1	158	2
Option D	42	18	48	
Option E	140	82	112	2
Option F	21	17	4	
Option G	125	86	37	2
Option H	157	3	152	2
Option I	20	16	4	
Option J	123	86	35	2

The features that require periodic operations will be the exercising of the pumps and emergency generators at the various pump stations, the testing of the gate structures at the various road crossings, grass cutting of the levee slopes and toe areas and the filling of rilled areas within the embankment due to surface erosion. Scheduled maintenance should include periodic greasing of all gears and coupled joints, maintaining any battery backup systems, and replacement of standby fuel supplies.

3.4.3.12 Real Estate Requirements

Real Estate requirements for Line of Defense 4, Harrison County Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches, and culvert/pump station facilities.

Based on the footprint of the Option A, 20.0 foot elevation, it was determined that approximately 1512 parcels and 756 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 756 relocations.

Based on the footprint of the Option B, 30.0 foot elevation, it was determined that 1688 parcels and 835 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 835 relocations.

Based on the footprint of the Option C, 40.0 foot elevation, it was determined that 1927 parcels and 938 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.161 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 938 relocations.

Based on the footprint of the Option D, 20.0 foot elevation, it was determined that 568 parcels and 174 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 174 relocations.

Based on the footprint of the Option E, 30.0 foot elevation, it was determined that 1916 parcels and 1172 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 7 pump stations will require approximately 0.23 of an acre each for a total of 1.61 acres. Lands required for construction of the levee will be acquired in fee simple interest, and lands for the drainage ditches that will be constructed outside the levee footprint will be acquired either in easement or fee as necessary. Based on the number of structures being impacted, the assumption is that there will be 1172 relocations.

Based on the footprint of the Option F, 20.0 foot elevation, it was determined that 76 parcels and 38 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction of the levee will be acquired in fee simple interest. Footprints of the drainage ditches for this option appear to be within the footprint of the lands being acquired for the levee. Based on the number of structures being impacted, the assumption is that there will be 38 relocations.

Based on the footprint of the Option G 30.0 foot elevation, it was determined that 189 parcels and 104 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction of the levee will be acquired in fee simple interest. Footprints of the drainage ditches for this option appear to be within the footprint of the lands being acquired for the levee. Based on the number of structures being impacted, the assumption is that there will be 38 relocations.

Based on the footprint of the Option H 40.0 foot elevation, it was determined that 209 parcels and 101 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 14 pump stations will require approximately 0.23 of an acre each for a total of 3.22 acres. Lands required for construction of the levee will be acquired in fee simple interest. Footprints of the drainage ditches for this option appear to be within the footprint of the lands being acquired for the levee. Based on the number of structures being impacted, the assumption is that there will be 101 relocations.

Based on the footprint of the Option I 20.0 foot elevation, it was determined that 225 parcels and 122 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction of the levee will be acquired in fee simple interest. Footprints of the drainage ditches for this option appear to be within the footprint of the lands being acquired for the levee. Based on the number of structures being impacted, the assumption is that there will be 122 relocations.

Based on the footprint of the Option J 30.0 foot elevation, it was determined that 171 parcels and 92 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 9 pump stations will require approximately 0.23 of an acre each for a total of 2.07 acres. Lands required for construction of the levee will be acquired in fee simple interest. Footprints of the drainage ditches for this option appear to be within the footprint of the lands being acquired for the levee. Based on the number of structures being impacted, the assumption is that there will be 92 relocations.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands

will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

Table 3.4.3.12-1 below summarizes the real estate requirements for the various alternatives.

Table 3.4.3.12-1.
Real Estate Requirements - LOD4 Harrison County

Option	Impacted Parcels	Impacted Structures	# Pump Stations/AC	Relocations
Option A	1,512	756	7 1.16 AC	756
Option B	1,688	835	7 1.16 AC	835
Option C	1,927	938	7 1.16 AC	938
Option D	568	174	7 1.16 AC	174
Option E	1,916	1,172	7 1.16 AC	1,172
Option F	76	38	9 2.07 AC	38
Option G	189	104	9 2.07 AC	104
Option H	209	101	14 3.22 AC	101
Option I	225	122	14 3.22 AC	122
Option J	171	92	9 2.07 AC	92

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.4.3.13 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities and Highway 90. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.4.3.14 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.4.3.15 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.4.3.16 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.4.3.17 Government Owned Property

There are 1-5 Government owned parcels within the footprint of the project that will be impacted depending on the option recommended for construction. In viewing the footprint, it is noted that the parcels will be impacted where they abut Highway 90. The parcels may be impacted by approximately 20-30%. Land and structure values are not listed in the public records. Ownership is listed in public records as US Govt, US Veterans Hospital and United States of America. Specific impacts to Government owned lands will be determined during PED.

3.4.3.18 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.4.3.19 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.4.3.20 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.4.3.21 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

Table 3.4.3.21-1 shows the number of expected relocations for each Option. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

Table 3.4.3.21-1.
PL 91-646 - Relocation Assistance

Option	Number of Relocations
Option A	756
Option B	835
Option C	938
Option D	174
Option E	1,172
Option F	38
Option G	104
Option H	101
Option I	122
Option J	92

3.4.3.22 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many

of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.4.3.23 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.4.3.24 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and for drainage ditches constructed outside the footprint of the levee, fee or the Drainage Ditch Easement will be used as appropriate. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.4.3.25 Real Estate Estimate

A summary of the cost for each option is at Table 3.4.3.25-1. The real estate cost estimates at Tables 3.4.3.25-2 through 3.4.3.25-11 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.4.3.25-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	1,512	756	253,268,000

3.4.3.26 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both

in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.4.3.27 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.4.3.27-1 through 3.4.3.27-10 shows the CWBS for real estate activities.

3.4.4 Back Bay of Biloxi Surge Barrier

In order to protect the properties surrounding Biloxi Bay and along the lower portions of the various rivers and streams flowing into the bay, a barrier would be required at some point to block storm waters during major storm events. A search of other similar facilities constructed world wide revealed that the structure model best satisfying both the engineering and socio-ecological necessities of this site was that used for the Thames River Barrier in London, UK. The structure tentatively investigated for incorporation into this work was patterned after the Thames River Barrier with certain minor modifications to adapt to the site and environment specific conditions. A photograph of the Thames River Gates is at Figure 3.4.4-1. The Biloxi Bay watershed covers approximately 640 square miles and is comprised of six sub-basins that stretch across Harrison, Hancock, Stone and Jackson County, MS.

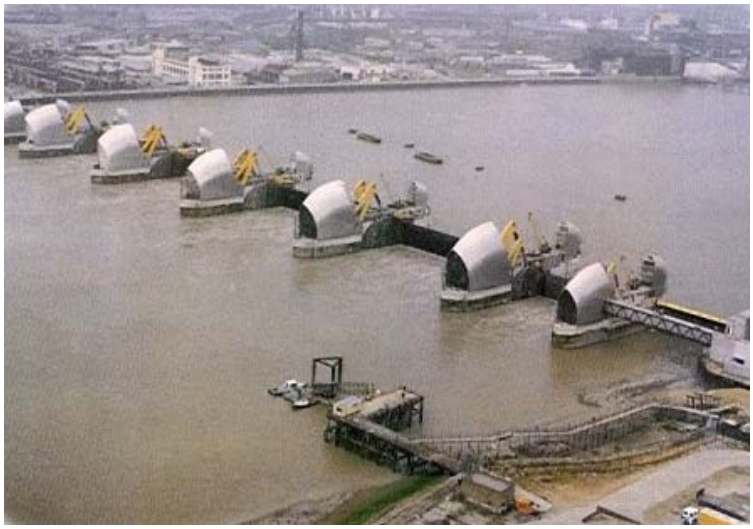

Figure 3.4.4-1. Thames River Gates, London, UK

In the event of an imminent hurricane, the gates across the Back Bay of Biloxi would be closed, and flow from the rivers feeding these bays, as well as local runoff would pond behind the gates. The tentative location of the barrier chosen for this study is shown below in Figure 3.4.4-2. The alternatives for this proposed measure are identified as Option A, Option B and Option C.

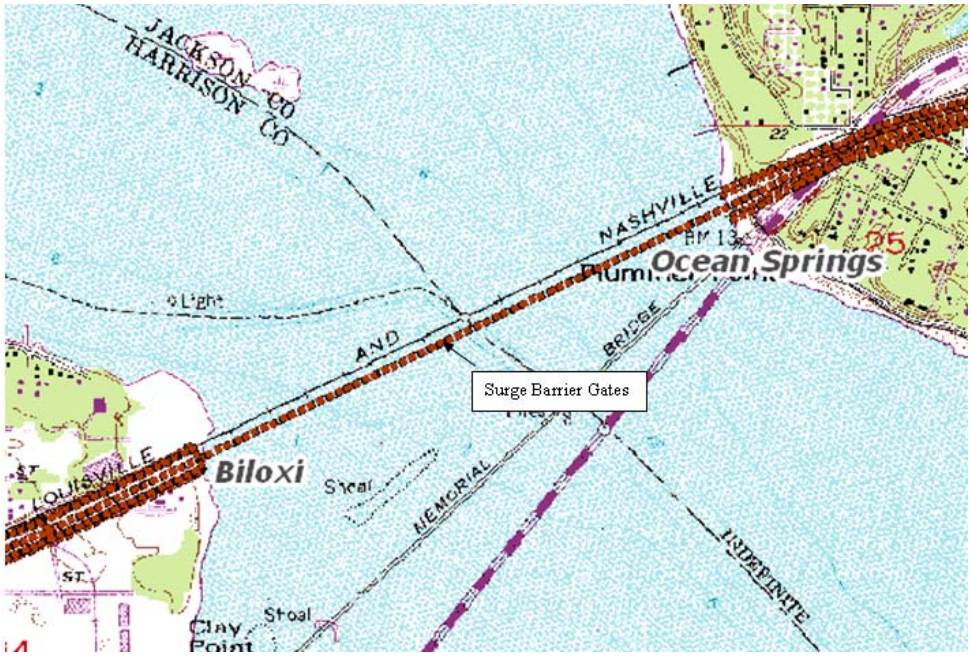

Figure 3.4.4-2. Back Bay of Biloxi Surge Barrier Location

3.4.4.1 Option A - Elevation 20.0 ft NAVD88

Option A is the design and construction of a rising sector gate in the Back Bay of Biloxi creating a barrier to elevation 20.0.

3.4.4.2 Option B - Elevation 30.0 ft NAVD88

Option B is the design and construction of a rising sector gate in the Back Bay of Biloxi creating a barrier to elevation 30.0.

3.4.4.3 Option C - Elevation 40.0 ft NAVD88

Option C is the design and construction of a rising sector gate in the Back Bay of Biloxi creating a barrier to elevation 40.0.

3.4.4.4 Project Description

The alignment suggested herein for the barrier structure would run parallel with and south of the Railroad Bridge crossing Biloxi Bay. This would approximate the shortest route across the inlet leading from the Mississippi Sound into the bay. As the preliminary layout of the barrier was developed it became apparent that, because of the excavation required, a significant amount of separation would be required between the railroad bridge and the ultimate location of the structures included in the barrier. For this study the centerline of the barrier was positioned approximately 260 feet from the center of the railroad bridge. This was left unaltered for all protection levels. The entire barrier would be approximately 6,100 feet in length from water's edge to water's edge, and would consist of rock fill levees extending from the overland levee at each bank for some distance into the bay and enveloping the mass concrete non-overflow wall sections leading to each end of the gated structure.

The points at which the barrier would come ashore in Jackson County on the east and Harrison County on the west, are in urban areas with extensive residential and commercial development. Several structures would need to be relocated and it is uncertain the extent to which existing utilities might have to be relocated to clear the way for this facility.

Structurally, the Barrier as configured for this study would consist of a series of 25 large stainless steel clad, structural steel framed gates called rising sector gates. Each of these would be supported on reinforced concrete piers resting on large continuous concrete sills with pile foundations. The tentative layout used to estimate the scope of the structure was configured having gates 132 feet long mounted on 28-foot wide piers. The number of gates was determined by the extent of water having depth sufficient to support their operation. To facilitate as nearly as possible the normal ebb and flow of tide waters through the barrier, the concrete connector wall and rock fill portions of the barrier either side of the gated structure would be fitted with a series of closely spaced low level gated culverts. The gate and pier heights were varied to accommodate the "level of protection" under consideration. The three elevations selected for this study were 20, 30, and 40 NAVD88. In each instance the gate heights were set to match the protection level elevations with pier heights set approximately 3 feet higher to provide minor wave clearance for protection of operating equipment. Atop each pier an operating machinery block would be mounted to house the operating equipment. Operating and utility access would be provided through two continuous tunnels passing through the sill section and the rock fill, to operating facilities located on each bank.

In order to assure proper functioning of the facilities once they are placed in service a program of Operations and Maintenance would be developed by the U.S. Army Corps of Engineers, in conjunction and cooperation with the affected state and local entities. This O & M Plan would

address specific responsibilities as to daily operation of the facilities, the periodic testing and maintenance of the operating machinery, maintenance of specified stocks of replacement parts, security of the facilities, and maintenance of any buildings and grounds associated with the operation and maintenance of the facilities. As presently envisioned, this O & M responsibility would remain under control of the U.S. Army Corps of Engineers and would be administered under its Operations mission.

3.4.4.5 Real Estate Requirements

Real Estate requirements for Line of Defense 4, Back Bay of Biloxi Surge Barrier include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct, rock levees and an elevated gate barrier in the Back Bay of Biloxi with operating facilities located on each landward bank of the barrier. The rock levees on either side of the gates will tie into the LOD4 inland barrier. There will be 2 operating facilities, one located in Jackson County and the other in Harrison County. Each site will be comprised of approximately 5 acres and these will be acquired in fee. The real estate cost estimate will be the same for each option as they all have the same requirements.

For those lands required for construction that lay below the mean high water mark, navigation servitude will apply. Navigation servitude is the dominant right of the Government under the Commerce Clause of the U.S. Constitution (U.S. CONST. Art.I,§8,cl.3) to use, control and regulate the navigable waters of the United States and the submerged lands hereunder for various commerce-related purposes including navigation and flood control. In tidal areas, the servitude extends to all lands below the, mean high water mark. In non-tidal areas, the servitude extends to all lands within the bed and banks of a navigable stream that lie below the ordinary high water mark. The determination of the availability of the navigation servitude should be made on a case by case basis and consists of a two -step process. First the government must determine whether the project serves a purpose that has a nexus to navigation. Purposes recognized by the courts to have the nexus include navigation, flood control and hydroelectric power. If determined that such a nexus exists, then the second step is to determine whether the land at issue is located below the mean or ordinary high water mark of a navigable watercourse. As a general rule, the Government does not acquire interests in real property that it already possesses or over which its use or control is or can be legally exercised. Therefore, if the navigation servitude is found to be available as a result of application of the process described in subparagraph b of this paragraph, then the Government will generally exercise its rights hereunder and, to the extent of such rights, will not acquire a real property interest in the land to which the navigation servitude applies. Generally, it is the policy of the U.S. Army Corps of Engineers (USACE) to utilize the navigation servitude in all situations where available, for cost shared and full Federal projects. The determination of availability will be made during PED.

3.4.4.6 Utility/Facility Relocation

It is probable that there will be some utility/facility relocations for this plan. Specific requirements are unknown at this time but will be defined during PED. See Chapter 2 Section 2.10 for more detailed discussion.

3.4.4.7 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.4.4.8 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

3.4.4.9 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.4.4.10 Government Owned Property

There are no known Government owned lands within the proposed project.

3.4.4.11 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.4.4.12 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.4.4.13 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.4.4.14 Public Law 91-646, Relocation Assistance Benefits

No relocations are expected with this alternative.

3.4.4.15 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.4.4.16 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.4.4.17 Estates for Proposed Project

All lands required for the operating facilities will be acquired in Fee Simple.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.4.4.18 Real Estate Estimate

The real estate cost estimate at Table 3.4.4.18-1 includes the land cost for acquisition of land, permits, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a temporary work area. The requirement, if any, for a temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.4.4.18-1.

	Totals			**1,767,354**
	Rounded			**1,767,000**

3.4.4.19 Summary of Potential Real Estate Issues

It is expected that navigation servitude will be exercised to construct the surge barrier in the Back Bay of Biloxi. This determination will be made during PED.

It is probable that there will be some utility/facility relocations for this plan. Specific requirements are unknown at this time but will be defined during PED.

The requirement for temporary work areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements.

Should temporary work areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with temporary work areas and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

3.4.4.20 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 3.4.4.20-1 shows the CWBS for real estate activities.

3.4.5 Jackson County Inland Barrier

Residential and business areas along the coast in Jackson County are susceptible to damage from storm surges associated with hurricanes. Earthen levees were evaluated for protection of these areas. The levees were evaluated at elevations 20 ft NAVD88 and 30 ft NAVD88 and 40 ft NAVD88. The top width was assumed 15 ft with side-slopes of 1 vertical to 3 horizontal. These alternatives are Identified as Option A, Option B and Option C. The location of the proposed project in Jackson County is shown in Figures 3.4.5-1. The levee will be constructed parallel to the CSX Railroad, Highway 57 and Highway 90.

Jackson County is located on the east side of the Mississippi at the Mississippi Sound coast. The main residential and business area is at Ocean Springs, which is mostly south of the proposed levee. Ground elevations over the areas behind the proposed levee vary between elevations 10-20 ft NAVD88 at low areas to as high as 50 ft NAVD88. The area is drained by Old Fort Bayou.

Figure 3.4.5-1. Vicinity Map Jackson County, MS

3.4.5.1 Option A - Elevation 20.0 ft NAVD88

This option consists of constructing a levee to elevation 20 ft NAVD88 parallel to Highway 90 along with the internal sub-basins and levee culvert/pump locations. The levee will be located mostly along high ground so ponding at the levee would be minimal. Ponding will occur on the outside of the levee which would require ditching to other drainage basins.

3.4.5.2 Option B - Elevation 30.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 30.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.5.3 Option C - Elevation 40.0 ft NAVD88

The alignment of the levee is the same as Option A, above but with an elevation of 40.0 feet. The only difference between the description of this option and preceding description of Option A is the height of the levee, pumping facilities, number of roadway and railroad intersections, and the length of the levee culverts.

3.4.5.4 Project Description

The location of the proposed levee project is shown in Figures 3.4.5.4-1 through 3.4.5.4-3. As described, the levee will be an earthen berm constructed either at elevation 20.0 feet, 30.0 or 40.0 feet along with the internal sub-basins and levee culvert/pump locations. Drainage on the interior of the ring levee would be collected at the levee and channeled to culverts placed in the levee. The culverts would have flap gates on the seaward ends to prevent backflow when the water in Mississippi Sound is high. An additional closure gate would also be provided at every culvert in the levee for control in the event the flap gate malfunctions. In addition, pumps would be constructed near the outflow points to remove water from the interior during storm events occurring when the culverts are closed because of high water in the sound. Drainage ditches along the toe of the levee will be required to assure that smaller basins can be drained to a culvert/pump site. Figure 3.4.5.4-4 shows the proposed locations of the pump/culvert sites. During some hurricane events, when the gates are shut, and rainfall exceeds the average 10-yr intensity over the basin, some ponding from rainfall will occur. Further studies will detail the requirement for the appropriate ponding areas, pump sizes, or buyouts in the affected areas. In order to prevent hurricane surges from circumventing the levee, surge barrier gates would be constructed across both Biloxi Bay and St. Louis Bay. In the event of an imminent hurricane, barrier gates across the Back Bay of Biloxi would be closed, and flow from the Biloxi and Tchoutacabouffa Rivers, as well as local runoff would pond behind the gates.

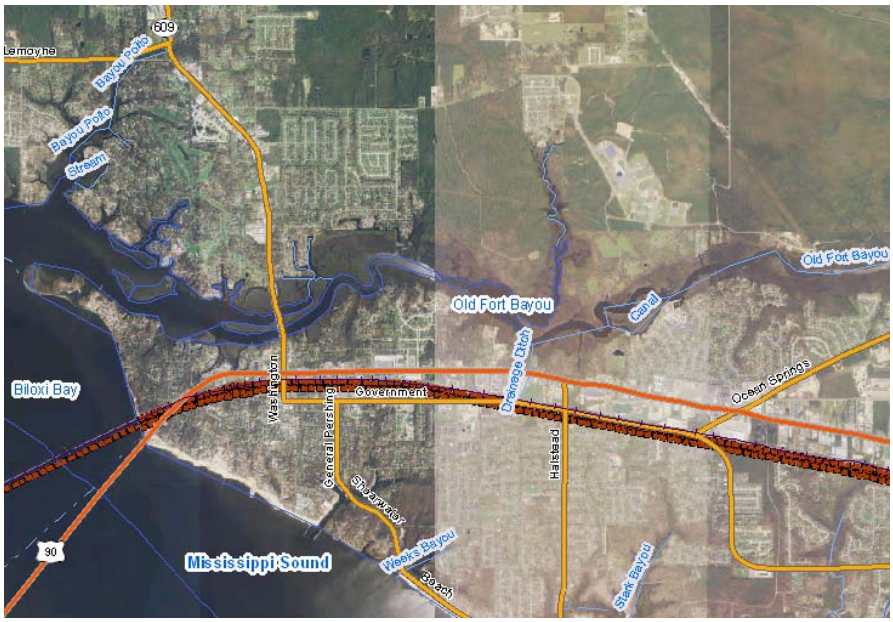

Figure 3.4.5.4-1. Jackson County Inland Barrier

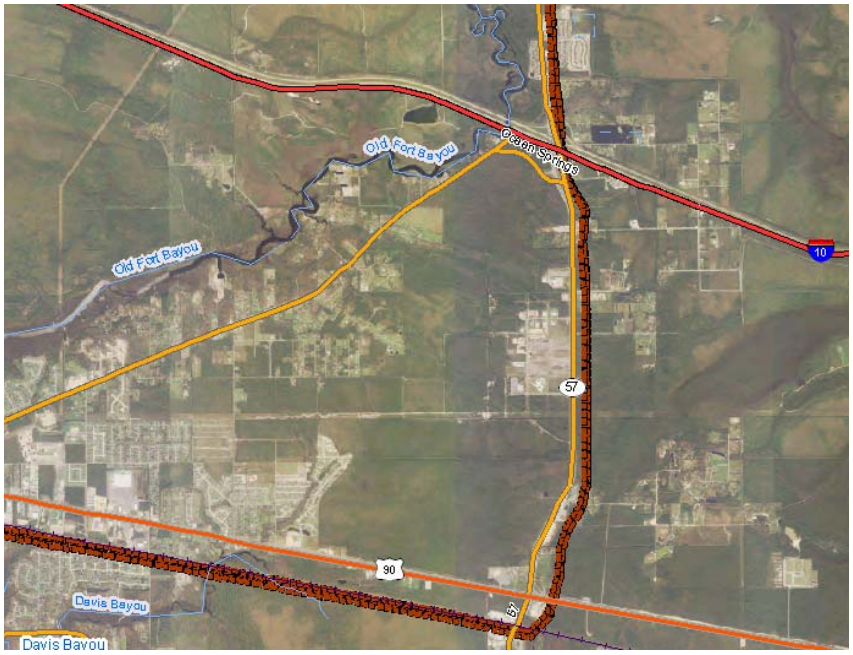

Figure 3.4.5.4-2. Jackson County Inland Barrier

Figure 3.4.5.4-3. Jackson County Inland Barrier

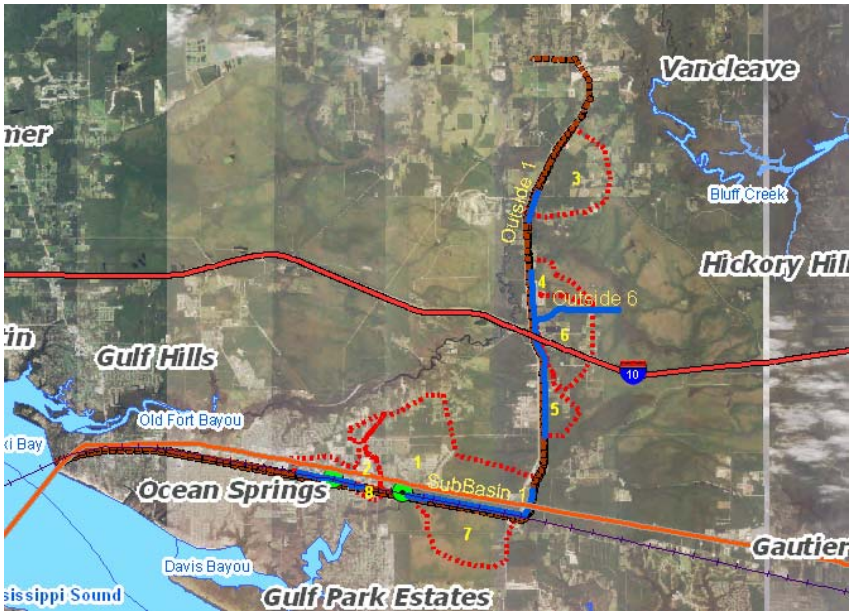

Figure 3.4.5.4-4. Pump/Culvert/Sub-basin Site Locations

The inland barrier earthen levee section will have one vertical to three horizontal side slopes with a fifteen foot crest width. All work areas to receive fill shall be cleared and grubbed of all trees and surface organics and all existing foundations, streets, utilities, etc. will be removed and the subsequent cavities backfilled and compacted. The levee will be constructed of sand clay materials obtained from off site commercial sources, and trucked to the work area. The final surface will be armored by the placement of 24 inch thick gabion mattress filled with small stone for erosion protection during an event that overtops the levee. The armoring will be anchored on the front face by trenching and extend across the downstream slope and a 25 foot area beyond the toe. The front side of the levee and all non critical surface areas will be subsequently covered by grassing. In order to maintain the natural runoff patterns culverts would be inserted through the protection line at appropriate locations. For Options A, B, and C, drainage features would be required at 2 locations with the culvert requirement ranging from seven 7' wide by 3' high, to eleven 10' wide by 4; high water passages. Each water passage would be fitted with both a flap gate at the outlet end and a sluice gate placed near the center of the culvert with a vertical operator stem extending through an access shaft to the top of levee elevation.

Road crossings will incorporate small gate structures or ramping over the embankment where the surface elevation is near that of the crest elevation. The elevation relationship of the crest and the adjacent railroad will be a governing factor. At each point where a roadway crosses the protection line the decision must be made whether to maintain this artery and adapt the protection line to accommodate it, or to terminate the artery at the protection line and divert traffic to cross the protection line at another location. For this study it was assumed that all roadways and railways crossing the levee alignment would be retained except where it was very evident that traffic could be combined without undue congestion. Once the decision has been made to retain a particular roadway, it must then be determined how best to configure the artery to conduct traffic across the protection line. The simplest means of passing roadway traffic is to ramp the roadway over the protection line. This alternative is not always viable because of severe right-of-way restraints caused by extreme levee height, urban congestion, etc. In such instances other methods can be used

including partial ramping in combination with low profile roller gates. In more restricted areas full height gates which would leave the roadway virtually unaltered might be preferable, even though this alternative would usually be more costly than ramping. In some extreme circumstances where high levees are required to pass through very congested areas, installation of tunnels with closure gates may be required.

Because of the extreme gradient restrictions necessarily placed on railway construction, it is practically never acceptable to elevate a railway up and over a levee. Therefore, the available alternatives would include gated pass through structures. Because of the vertical clearance requirements of railroad traffic all railroad pass through structures for this study were configured having vertical walls on either side of the railway with double swing gates extending to the full height of the levee. Roadway and railway intersections are not applicable to Option A, 20.0 and Option B, 30.0. At Option C, elevation 40.0, 3 roadway intersections would have to be accommodated. It was determined that roller gate structures would suffice for all thee of these locations.

There are two sites in Jackson County that would require special flood protection with the flood protection level set at elevation 40, the court facilities located immediately south of the protection line in downtown Biloxi and similar governmental facilities in downtown Moss Point. The Biloxi facilities would require a three sided Tee Wall structure approximately 1410 feet long originating and terminating in the levee at its northwest and northeast ends. It would be fitted with four face sealing roller gates to close off the required street and driveway access points in time of flood. The Moss Point Tee Wall would be similarly configured and would extend approximately 1552 feet. It would require two roadway closure gates.

The features that require periodic operations will be the exercising of the pumps and emergency generators at the various pump stations, the testing of the gate structures at the various road crossings, grass cutting of the levee slopes and toe areas and the filling of rilled areas within the embankment due to surface erosion. Scheduled maintenance should include periodic greasing of all gears and coupled joints, maintaining any battery backup systems, and replacement of standby fuel supplies.

3.4.5.5 Real Estate Requirements

Real Estate requirements for Line of Defense 4, Jackson County Levee include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to construct an earthen levee, drainage ditches and 2 pump station facilities.

Based on the footprint of the Option A, 20.0 foot elevation, it was determined that approximately 323 parcels and 171 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 2 pump stations will require approximately 0.23 of an acre each for a total of 0.46 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 171 relocations.

Based on the footprint of the Option B, 30.0 foot elevation, it was determined that 361 parcels and 191 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 2 pump stations will require approximately 0.23 of an acre each for a total of 0.46 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 191 relocations.

Based on the footprint of the Option C, 40.0 foot elevation, it was determined that 404 parcels and 217 structures would be impacted. The acreage to be acquired for the levee is unknown. It is known that the 2 pump stations will require approximately 0.23 of an acre each for a total of 0.46 of an acre. Lands required for construction of the levee will be acquired in fee simple interest. Based on the number of structures being impacted, the assumption is that there will be 217 relocations.

Any modifications to the roadways and utilities will most probably need to be accomplished through a relocation contract. This will be further investigated and confirmed during PED.

Footprints for drainage ditches are not available at time of this report. However, from the figures it appears that acquisition of additional lands for drainage ditches outside the footprint of the levee will be minimal. Until final plans and specifications are completed, land requirements for drainage ditches are assumed to be covered by contingency. This additional requirement will be determined during PED.

During the formulation of the nonstructural (NS) measures and alternative plans, the NS PDT became aware of local efforts by the leadership of Moss Point, MS to relocate several public buildings out of the hurricane surge zone to a higher elevation within the municipal area. A series of meetings with the Mayor of Moss Point and other city officials followed to work toward development of a plan to relocate these facilities that are critical to the safety and continued operations of the local government. As a result of the meetings the NS PDT developed a Pilot Relocations Project for Moss Point, MS. The public buildings included in the pilot project are the city hall, police station, fire station and community recreation center. As these structures are owned and operated by the City of Moss Point and are considered essential to the operation of the city, they would therefore be eligible for facility relocation. The description of the relocations measure, eligible facilities and costs are included in the Nonstructural Appendix at Section 4.3.9.6 Pilot Moss Point Public Buildings Relocations Project. Any substitute facilities relocations will be performed under a Real Estate Relocation Contract. The cost for these relocations is captured in the Nonstructural Appendix but final crediting would be considered as part of the LERRD credit.

An assumption is made that excavated materials from clearing, snagging, and construction of ditches, etc. will be disposed of in county owned or commercial landfills. However, In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

The recommended plan proposes to use material from an inventory of upland borrow sites to construct the levee. A specific site has not been identified or confirmed for use at time of this report. Typically if borrow sites are required, this would be considered a part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland borrow site with the cost of using a commercial borrow site and make a determination which method is most cost effective. The requirement for temporary work areas is unknown. Sponsor owned lands will be used if available. Otherwise, this may be an additional real estate requirement, and will be further defined during PED.

3.4.5.6 Utility/Facility Relocation

The plan calls for roads to be ramped over the proposed levee and possible relocation of utilities. An assumption is made that this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. As discussed above any municipal buildings designated as essential to the operation of the city could be relocated as substitute facilities relocations See Chapter 2 Section 2.10 for more detailed discussion, and the Nonstructural Appendix at Section 4.3.9.6.

3.4.5.7 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

3.4.5.8 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix for a full discussion on environmental effects.

3.4.5.9 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit "A" to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

3.4.5.10 Government Owned Property

There are 7-8 Government owned parcels within the footprint of the project that will be impacted depending on the option recommended for construction. In viewing the footprint, it is noted that the parcels will be impacted where they abut Highway 90 and Highway 57. The parcels may be impacted by approximately 10-30%. Land values are listed in the public records, but no improvement values are listed. Ownership is listed in public records as United States of America and USA Dept of the Navy. Specific impacts to Government owned lands will be determined during PED.

3.4.5.11 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

3.4.5.12 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

3.4.5.13 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

3.4.5.14 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 171 relocations in Option A, approximately 191 relocations in Option B, and approximately 217 relocations in Option C. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

3.4.5.15 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

3.4.5.16 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

3.4.5.17 Estates for Proposed Project

All lands required for the levee will be acquired in Fee Simple. Should a borrow site be required, the Borrow Easement will be used. The Temporary Work Area Easement will be used for staging or temporary work areas, and the Drainage Ditch Easement will be used for construction of any drainage ditches outside the footprint of the levee as required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

BORROW EASEMENT.

A (temporary) (perpetual and assignable) right and easement to clear, borrow, excavate and remove sand, soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. _____, _____ and _____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights and easement hereby acquired.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

DRAINAGE DITCH EASEMENT.

A perpetual and assignable easement and right-of-way in, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and _____) to construct, maintain, repair, operate, patrol and replace a drainage ditch, reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

3.4.5.18 Real Estate Estimate

A summary of the cost for each option is at Table 3.4.5.18-1. The real estate estimates at Tables 3.4.5.18-2 through 3.4.5.18-4 include the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of

lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a borrow site or temporary work area. The requirement, if any, for a borrow site or temporary work area will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 3.4.5.18-1.
Real Estate Cost Summary

Option	Impacted Parcels	Relocations	Total Cost
Option A - 20.0	323	171	58,506,000
Option B - 30.0	361	191	66,571,000

3.4.5.19 Summary of Potential Real Estate Issues

The requirement for temporary work areas, disposal or borrow areas has not been identified. Should these areas be required, these would be considered as part of the LERRD requirements. Typically if disposal or borrow sites are required, Real estate would provide an analysis during PED to compare the cost of acquiring an these sites with the cost of using a commercial sites and make a determination which method is most cost effective. See Section 2.8 Borrow Areas on page 5.

Should drainage ditches, temporary work areas, disposal or borrow areas become a necessary real estate acquisition requirement, valuation of lands will be performed. Land costs associated with these areas, and administrative costs will be added to the Real Estate Cost Estimate. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Any requirement for mitigation lands will be identified during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both

in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

3.4.5.20 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Tables 3.4.5.20-1 through 3.4.5.20-3 shows the CWBS for real estate activities.

3.5 Line of Defense 5 - Retreat and/or Relocation of Critical Facilities

Hurricanes are a naturally occurring phenomena that wreak havoc on natural and man-made environments through three different but related mechanisms: torrential rainfall, high winds, and storm surge. While each of these can produce costly outcomes in their own right, storm surge is typically the most damaging and particularly deadly. It is also the most difficult and costly to provide enduring and confident protection against. However, if one cannot be reached by storm surge by virtue of being on ground at elevation higher than any storm surge might reach, one cannot be directly damaged by it. The limit of storm surge represents the first line of avoidance to hurricane related damages. It therefore makes sense to identify the potential inland limit of storm surge so that prudent choices might be made by any and all regarding their exposure to damage by storm surge.

The primary measures identified for the project area include permanent acquisitions, flood proofing by elevation and other means, relocations of public buildings, flood preparedness and evacuation planning, public education, changes in the current municipal and county NFIP and building codes, implementation of either a transfer of development rights or purchase of development rights program, potential changes in zoning ordinances, development impact fees, and redirection of new development. These measures have been combined into several plans that can be implemented by either agencies of the Federal government or collaboratively by those agencies and state, county and local governmental units. In several cases, only local jurisdictions can implement some of the measures identified.

Computer simulations have predicted how far inland storm surge will extend if the worse-case hurricane or maximum possible intensity (MPI) event hits the Mississippi coast.

This line of defense is shown in Figure 3.5-1. This line represents a line of safety where homes, facilities or transportation routes north of this line should not be directly damaged by storm surge. This would be an area where hospitals, schools, emergency response and management facilities, power stations, water supply facilities, or other critical infrastructure might be located. It would also represent an area whereby future development (commercial, industrial, or residential) might be redirected. The maximum water level along the Mississippi coastline was determined to be approximately 30 ft along the entire western half of the state and east of Pascagoula. The landward extent of the inundation indicates the storm surge reaches Interstate 10 for much of the western portion of the state. Lower peaks near Biloxi and Mobile Bay (24-27 ft) may be attributed to the protection afforded by the barrier islands. The line of defense accordingly approximates the 24 to 30 ft. (NAVD '88 datum) contours.

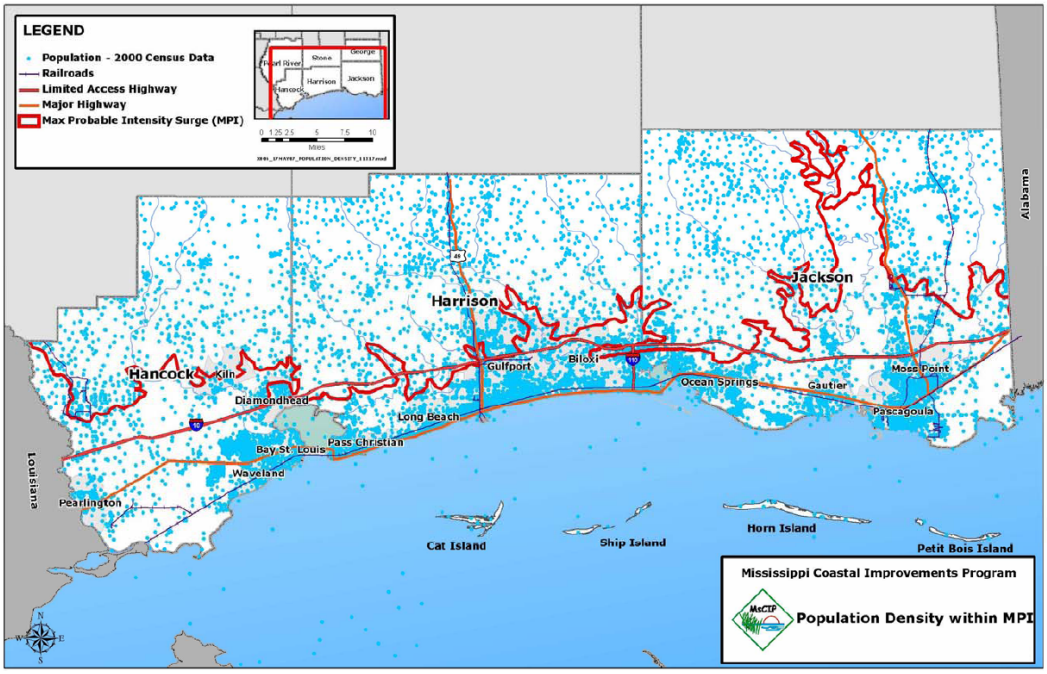

Figure 3.5-1. Maximum Probable Intensity Storm Surge Limits

The area seaward of the line of defense is occupied by natural, rural, suburban, and urban environments and residential, commercial, and industrial development. Approximately 1/3 (visually estimated) of the coastal county areas fall within the estimated surge limits. With the exceptions of seawalls fronting Harrison County, Bay St. Louis, and the city of Pascagoula, there are no hurricane storm damage reduction structures in place. These structures provide little inundation protection over what the natural ground elevation would provide for and do not provide hurricane protection for surge events approaching or exceeding the 1 in 100 annual chance event.

There are no alternative alignments to this line of defense. The line of defense alignment could be changed or modified due to any of the following: (a) revised hydrodynamic modeling results; (b) the

construction of storm damage reduction measures, such as levees and/or storm surge barriers; (c) sea level rise; (d) construction of other infrastructure (e.g. roadway embankments) that might materially obstruct or alter surge flow pathways.

A thorough discussion of non-structural alternative measures is provided in the Non-Structural Measures Plan Formulation Appendix.

No real estate plan has been prepared for this line of defense as specific sites for relocation of facilities have not been identified. A plan will be prepared during PED should this plan be approve for implementation.

CHAPTER 4. NONSTRUCTURAL

Formatted: Bullets and Numbering

Flood damage reduction measures are divided into two distinct components: structural and nonstructural. Application of nonstructural measures or those measures directly associated with modifying the location, construction or operation of property, structures, and facilities located in hazard areas is one method of reducing storm/hurricane-related damages and saving lives that are at-risk. There are numerous nonstructural methods, but the Real Estate Appendix focuses on permanent evacuation of the hazard areas.

Permanent acquisition of coastal properties is an effective way to reduce flood damages and loss of life due to hurricane surge drowning. Existing properties with or without structures can be purchased under the provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (P.L. 91-646). Permanent acquisition furthers the objectives of migrating the population northward and away from the coast. This nonstructural measure would be applied to a quilt-like, land use pattern of residential, commercial, and institutional uses as well as both occupied and vacant parcels. The purpose of purchasing vacant parcels is to prevent future building on those parcels. Post-acquisition use of the land could include wetland habitat restoration, recreation or open space uses that would not result in re-establishment of damageable property,

4.1 Hancock County Acquisition

4.1.1 Project Description

High Hazard Zones: The nonstructural project delivery team (PDT) identified several zones within the project area, where due to extreme forces generated by storms and hurricanes, other measures such as elevation of an existing or rebuilt structure would not be prudent and may endanger the future occupants. Within these zones, successful emergency evacuation during a storm event would be highly improbable and dangerous for the responders, elevated structures may be prone to foundation failures due to waves and surge, elevation by placed fill material is prohibited or infeasible, and non-elevated structures would likely suffer total or significant losses. Each of these zones was graphically identified using GIS mapping and FEMA database information. There are three identified zones where permanent acquisition and evacuation of the property is the preferred nonstructural treatment. Those zones are:

The FEMA-identified V/VE Zone displayed on the National Flood Insurance Rate Maps (FIRM) within the project area. This “Velocity” water zone features high-energy wave action that was responsible for much of the building damages during the Katrina event and makes elevating structures or otherwise flood-proofing structures in-place very dangerous.

The FEMA-identified “catastrophic damages zone” which was identified in a “post-Katrina” damage assessment of FEMA insured structures within the project area. This zone included a preponderance of insured structures that had received damages in excess of 50% of the structure’s value. Field observations by the nonstructural PDT confirmed that most of those structures in the zone had been totally destroyed or severely damaged (major structural damages). This area includes the V/VE zone within its boundaries.

A flood damage zone was delineated extending 800 feet back from the beachfront within portions of Jackson County. The aforementioned “catastrophic damage zone” established by FEMA was based upon the Katrina event only and therefore did not account for the area of damages that could be expected along Jackson County should a Katrina-like storm strike at that location. The 800 feet zone approximated the spatial extent of observed total structure loss and severe structural damages

observed within Hancock and Harrison counties located closer to the Katrina landfall. Modifications of this zone's extent from the waterline could be made to account for intervening topography that would limit the impacts of surge and waves.

The preferred nonstructural measure in these three high-hazard zones would be permanent acquisition of the property under the general provisions of the Uniform Act. Relocations assistance would be provided to residential landowners and/or tenants of the property to locate and secure suitable replacement housing. Remaining structures, pavements, foundations and utilities on the acquired parcel would be demolished and removed to approved landfills. The acquired property could be reused for ecosystem restoration (wetlands), recreation or other purposes that would be in keeping with the identified flood hazards, the National Flood Insurance Program (NFIP) and the provisions of the Project Cooperation Agreement (PCA). The acquired property would be transferred to a local project sponsor for future Operations, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R).

A High Hazard Area Risk Reduction Plan (HARP) is currently being considered as a component of the comprehensive plan to address hurricane and storm damage reduction for certain areas within the Advisory Base Flood Elevation (ABFE) zones along the coast defined as high hazard areas. This plan which is supported by the State of Mississippi contemplates acquisitions in identified areas within Hancock, Harrison and Jackson Counties that should be considered for acquisition beginning in FY 2008 to facilitate relocation of homeowners outside the ABFE prior to their rebuilding. The plan under consideration is not specifically reflected in the nonstructural portion of the Real Estate Appendix. However, the HARP is incorporated in the report at Exhibit "C" to the Real Estate Appendix. Should the plan be authorized, significant adjustments will have to be made to the real estate costs for the buy out areas initially identified in the MsCIP report.

Non-Flood-proofing Zones: The nonstructural PDT also identified one additional zone within the project area where the preferred method of flood damage reduction would be permanent acquisition and evacuation of the property. This zone is located where water depths at the individual structure location occurring during the specified inundation event would exceed the maximum height of elevation prescribed by FEMA's 550 Guidelines for structure elevation. Those guidelines indicate that elevating structures more than 15 feet from the ground surface in hurricane areas would place the elevated structure in high-velocity hurricane force winds resulting in significant damages to the building. Any structure that would be required to be elevated more that 15 feet to place the first habitable or sales floor above the specified inundation level would be acquired. Using GIS software, a zone of inundation deeper than 13 feet (plus 2 feet of freeboard equals 15 feet) was identified within the project area where permanent acquisition would be the preferred method of nonstructural protection. The area for which permanent acquisition is recommended in Hancock County is shown in Figure 4.1.1-1. The acquisition area is shaded in dark green.

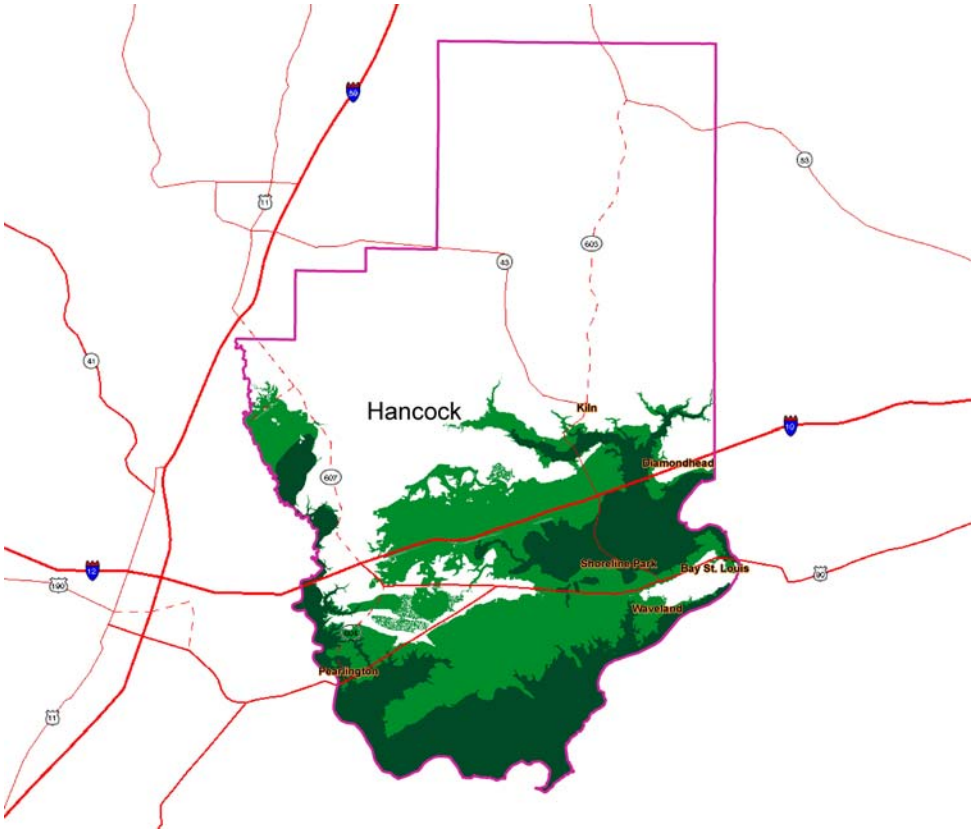

Figure 4.1.1-1. Location of Acquisition Areas in Hancock County (dark green)

4.1.2 Real Estate Requirements

Real Estate requirements for the Nonstructural Acquisition in Hancock County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire in fee simple approximately 17,845 impacted parcels and 10,192 structures. The project is divided into 9 reaches. The reaches are identified below in Table 4.1.2-1. Based on the number of structures being impacted, the assumption is that there will be 10,192 relocations to include residences and businesses. The plan calls to use an “approved landfill” for disposal of the demolished structures. An assumption is made that the excavated material will be disposed of in commercial or county landfills. In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Table 4.1.2-1.
Hancock County Acquisition Reaches

Reach	Impacted Parcels	Impacted Structures
1	997	268
2	9,911	7,133
3	2,202	1,326
4	922	373
5	2,714	447
6	567	540
7	450	79
36	32	2
38	50	24
Total	**17,845**	**10,192**

4.1.3 Utility/Facility Relocation

Specific information about relocation of utilities/facilities is unknown at this time. An assumption is made that if required, this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

4.1.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

4.1.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

4.1.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

4.1.7 Government Owned Property

There are approximately 35 Government owned parcels within the footprint of the project proposed for acquisition in Hancock County. These lands are in the vicinity of the John C. Stennis Space Center, or within lands shown as NASA Restricted Area on a state map. Land and structure values are not listed in the public records. Ownership is listed in public records as USA. Specific impacts to Government owned lands and/or structures will be determined during PED.

4.1.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

4.1.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

4.1.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

4.1.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 10,192 relocations in Hancock County. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. The availability of decent safe and sanitary housing is a potential problem. Large scale construction of new residences will most likely be required. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

4.1.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

4.1.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

4.1.14 Estates for Proposed Project

All lands acquired in the buy-out area will be acquired in Fee Simple. The Temporary Work Area Easement will be used for a disposal site if required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

4.1.15 Real Estate Estimate

The real estate cost estimate at Table 4.1.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a disposal site. The requirement, if any, for a disposal site will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 4.1.15-1.

		Totals			**4,241,807,844**
		Rounded			**4,241,808,000**

4.1.16 Summary of Potential Real Estate Issues

In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

If the nonstructural acquisition measure is approved, additional time would need to be allowed for staffing up to handle the increased workload for the large number of acquisitions.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

The availability of decent safe and sanitary housing is a potential problem. Large scale construction of new residences will most likely be required.

4.1.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 4.1.17-1 shows the CWBS for real estate activities.

4.2 Harrison County Acquisition

4.2.1 Project Description

High Hazard Zones: The nonstructural project delivery team (PDT) identified several zones within the project area, where due to extreme forces generated by storms and hurricanes, other measures such as elevation of an existing or rebuilt structure would not be prudent and may endanger the future occupants. Within these zones, successful emergency evacuation during a storm event would be highly improbable and dangerous for the responders, elevated structures may be prone to foundation failures due to waves and surge, elevation by placed fill material is prohibited or infeasible, and non-elevated structures would likely suffer total or significant losses. Each of these zones was graphically identified using GIS mapping and FEMA database information. There are three identified zones where permanent acquisition and evacuation of the property is the preferred nonstructural treatment. Those zones are:

The FEMA-identified V/VE Zone displayed on the National Flood Insurance Rate Maps (FIRM) within the project area. This “Velocity” water zone features high-energy wave action that was responsible for much of the building damages during the Katrina event and makes elevating structures or otherwise flood-proofing structures in-place very dangerous.

The FEMA-identified “catastrophic damages zone” which was identified in a “post-Katrina” damage assessment of FEMA insured structures within the project area. This zone included a preponderance of insured structures that had received damages in excess of 50% of the structure’s value. Field observations by the nonstructural PDT confirmed that most of those structures in the zone had been

totally destroyed or severely damaged (major structural damages). This area includes the V/VE zone within its boundaries.

A flood damage zone was delineated extending 800 feet back from the beachfront within portions of Jackson County. The aforementioned “catastrophic damage zone” established by FEMA was based upon the Katrina event only and therefore did not account for the area of damages that could be expected along Jackson County were a Katrina-like storm to strike at that location. The 800 feet zone approximated the spatial extent of observed total structure loss and severe structural damages observed within Hancock and Harrison counties located closer to the Katrina landfall. Modifications of this zone’s extent from the waterline could be made to account for intervening topography that would limit the impacts of surge and waves.

The preferred nonstructural measure in these three high-hazard zones would be permanent acquisition of the property under the general provisions of the Uniform Act. Relocations assistance would be provided to residential landowners and/or tenants of the property to locate and secure suitable replacement housing. Remaining structures, pavements, foundations and utilities on the acquired parcel would be demolished and removed to approved landfills. The acquired property could be reused for ecosystem restoration (wetlands), recreation or other purposes that would be in keeping with the identified flood hazards, the NFIP and the provisions of the PCA. The acquired property would be transferred to a local project sponsor for future OMRR&R.

A High Hazard Area Risk Reduction Plan (HARP) is currently being considered as a component of the comprehensive plan to address hurricane and storm damage reduction for certain areas within the Advisory Base Flood Elevation (ABFE) zones along the coast defined as high hazard areas. This plan which is supported by the State of Mississippi contemplates acquisitions in identified areas within Hancock, Harrison and Jackson Counties that should be considered for acquisition beginning in FY 2008 to facilitate relocation of homeowners outside the ABFE prior to their rebuilding. The plan under consideration is not specifically reflected in the nonstructural portion of the Real Estate Appendix. However, the HARP is incorporated in the report at Exhibit "C" to the Real Estate Appendix. Should the plan be authorized, significant adjustments will have to be made to the real estate costs for the buy out areas initially identified in the MsCIP report.

Non-Flood-proofing Zones: The nonstructural PDT also identified one additional zone within the project area where the preferred method of flood damage reduction would be permanent acquisition and evacuation of the property. This zone is located where water depths at the individual structure location occurring during the specified inundation event would exceed the maximum height of elevation prescribed by FEMA’s 550 Guidelines for structure elevation. Those guidelines indicate that elevating structures more than 15 feet from the ground surface in hurricane areas would place the elevated structure in high-velocity hurricane force winds resulting in significant damages to the building. Any structure that would be required to be elevated more that 15 feet to place the first habitable or sales floor above the specified inundation level would be acquired. Using GIS software, a zone of inundation deeper than 13 feet (plus 2 feet of freeboard equals 15 feet) was identified within the project area where permanent acquisition would be the preferred method of nonstructural protection. The area for which permanent acquisition is recommended in Harrison County is shown in Figure 4.2.1-1. The acquisition area is shaded in dark green.

Figure 4.2.1-1. Location of Acquisition Area in Harrison County (dark green)

4.2.2 Real Estate Requirements

Real Estate requirements for the Nonstructural Buy Out in Harrison County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire in fee simple approximately 10,912 impacted parcels and 5,911 structures. The project is divided into 11 reaches. The reaches are identified below in Table 4.2.2-1. Based on the number of structures being impacted, the assumption is that there will be 5,911 relocations to include residences and businesses. The plan calls to use an "approved landfill" for disposal of the demolished structures. An assumption is made that the excavated material will be disposed of in commercial or county landfills. In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Table 4.2.2-1.
Harrison County Acquisition Reaches

Reach	Impacted Parcels	Impacted Structures
8	3,623	1,819
9	44	9
10	1,945	1,157
12	1,047	469
13	650	412
15	85	47
16	78	19
18	1,502	984
19	46	4
20	1,397	851
50	495	140
Total	**10,912**	**5,911**

4.2.3 Utility/Facility Relocation

Specific information about relocation of utilities/facilities is unknown at this time. An assumption is made that if required, this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

4.2.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

4.2.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

4.2.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the

Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

4.2.7 Government Owned Property

There are approximately 11 Government owned parcels within the footprint of the project proposed for acquisition in Harrison County. Some of these lands are associated with Keesler AFB and the US Coast Guard. Land and structure values are not listed in the public records. Ownership is listed in public records as US Govt, US Govt-Keesler AFB, US of America, US of America (USCG) and US Veterans Hospital. Specific impacts to Government owned lands and/or structures will be determined during PED.

4.2.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

4.2.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

4.2.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

4.2.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 5,911 relocations in Harrison County. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. The availability of decent safe and sanitary housing is a potential problem.

Large scale construction of new residences will most likely be required. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

4.2.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

4.2.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

4.2.14 Estates for Proposed Project

All lands acquired in the buy-out area will be acquired in Fee Simple. The Temporary Work Area Easement will be used for a disposal site if required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

4.2.15 Real Estate Estimate

The real estate cost estimate at Table 4.2.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a disposal site. The requirement, if any, for a disposal site will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

Table 4.2.15-1.
Harrison County Acquisitions Estimate

a. Lands and Improvements/Permits					
10,912 Ownerships & 5,911 Improvements					1,722,841,076
					0
				Subtotal	1,722,841,076
b. Mineral Rights					0
c. Damages					0

Contingencies (25%)					544,550,394
		Totals			**2,722,751,970**
		Rounded			**2,722,752,000**

4.2.16 Summary of Potential Real Estate Issues

In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

If the nonstructural acquisition measure is approved, additional time would need to be allowed for staffing up to handle the increased workload for the large number of acquisitions.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

The availability of decent safe and sanitary housing is a potential problem. Large scale construction of new residences will most likely be required.

4.2.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 4.2.17-1 shows the CWBS for real estate activities.

Table 4.2.17-1.
Chart of Accounts - Harrison County Acquisitions

	Rounded			**2,722,752,000**

4.3 Jackson County Acquisition

4.3.1 Project Description

High Hazard Zones: The nonstructural project delivery team (PDT) identified several zones within the project area, where due to extreme forces generated by storms and hurricanes, other measures such as elevation of an existing or rebuilt structure would not be prudent and may endanger the future occupants. Within these zones, successful emergency evacuation during a storm event would be highly improbable and dangerous for the responders, elevated structures may be prone to foundation failures due to waves and surge, elevation by placed fill material is prohibited or infeasible, and non-elevated structures would likely suffer total or significant losses. Each of these zones was graphically identified using GIS mapping and FEMA database information. There are three identified zones where permanent acquisition and evacuation of the property is the preferred nonstructural treatment. Those zones are:

The FEMA-identified V/VE Zone displayed on the National Flood Insurance Rate Maps (FIRM) within the project area. This “Velocity” water zone features high-energy wave action that was responsible for much of the building damages during the Katrina event and makes elevating structures or otherwise flood-proofing structures in-place very dangerous.

The FEMA-identified “catastrophic damages zone” which was identified in a “post-Katrina” damage assessment of FEMA insured structures within the project area. This zone included a preponderance of insured structures that had received damages in excess of 50% of the structure’s value. Field

observations by the nonstructural PDT confirmed that most of those structures in the zone had been totally destroyed or severely damaged (major structural damages). This area includes the V/VE zone within its boundaries.

A flood damage zone was delineated extending 800 feet back from the beachfront within portions of Jackson County. The aforementioned “catastrophic damage zone” established by FEMA was based upon the Katrina event only and therefore did not account for the area of damages that could be expected along Jackson County were a Katrina-like storm to strike at that location. The 800 feet zone approximated the spatial extent of observed total structure loss and severe structural damages observed within Hancock and Harrison counties located closer to the Katrina landfall. Modifications of this zone’s extent from the waterline could be made to account for intervening topography that would limit the impacts of surge and waves.

The preferred nonstructural measure in these three high-hazard zones would be permanent acquisition of the property under the general provisions of the Uniform Act. Relocations assistance would be provided to residential landowners and/or tenants of the property to locate and secure suitable replacement housing. Remaining structures, pavements, foundations and utilities on the acquired parcel would be demolished and removed to approved landfills. The vacated property could be reused for ecosystem restoration (wetlands), recreation or other purposes that would be in keeping with the identified flood hazards, the National Flood Insurance Program (NFIP) and the provisions of the Project Cooperation Agreement (PCA). The vacated property would be transferred to a local project sponsor for future OMRR&R.

A High Hazard Area Risk Reduction Plan is currently being considered as a component of the comprehensive plan to address hurricane and storm damage reduction for certain areas within the Advisory Base Flood Elevation (ABFE) zones along the coast defined as high hazard areas. This plan which is supported by the State of Mississippi contemplates acquisitions in identified areas within Hancock, Harrison and Jackson Counties that should be considered for acquisition beginning in FY 2008 to facilitate relocation of homeowners outside the ABFE prior to their rebuilding. The plan under consideration is not specifically reflected in the nonstructural portion of the Real Estate Appendix. However, the HARP is incorporated in the report at Exhibit “C” to the Real Estate Appendix. Should the plan be authorized, significant adjustments will have to be made to the real estate costs for the buy out areas initially identified in the MsCIP report.

Non-Flood-proofing Zones: The nonstructural PDT also identified one additional zone within the project area where the preferred method of flood damage reduction would be permanent acquisition and evacuation of the property. This zone is located where water depths at the individual structure location occurring during the specified inundation event would exceed the maximum height of elevation prescribed by FEMA’s 550 Guidelines for structure elevation. Those guidelines indicate that elevating structures more than 15 feet from the ground surface in hurricane areas would place the elevated structure in high-velocity hurricane force winds resulting in significant damages to the building. Any structure that would be required to be elevated more that 15 feet to place the first habitable or sales floor above the specified inundation level would be acquired. Using GIS software, a zone of inundation deeper than 13 feet (plus 2 feet of freeboard equals 15 feet) was identified within the project area where permanent acquisition would be the preferred method of nonstructural protection. The area for which permanent acquisition is recommended for Jackson County is shown in Figure 4.3.1-1. The acquisition area is shaded in dark green.

Figure 4.3.1-1. Location of Acquisition Areas in Jackson County (dark green)

4.3.2 Real Estate Requirements

Real Estate requirements for the Nonstructural Acquisition in Jackson County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire in fee simple approximately 4,434 impacted parcels and 1,047 structures. The project is divided into 14 reaches. The reaches are identified below in Table 4.3.2-1. Based on the number of structures being impacted, the assumption is that there will be 1,047 relocations to include residences and businesses. The plan calls to use an “approved landfill” for disposal of the demolished structures. An assumption is made that the excavated material will be disposed of in commercial or county landfills. In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Table 4.3.2-1.
Jackson County Acquisition Reaches

Reach	Impacted Parcels	Impacted Structures
21	2,108	378
22	61	50
24	220	45
26	37	35
27	53	32
28	961	57
29	147	46
30	90	66
31	51	19
32	1	0
35	12	2
52	285	146
53	399	169
54	9	2
Total	**4,434**	**1,047**

4.3.3 Utility/Facility Relocation

Specific information about relocation of utilities/facilities is unknown at this time. An assumption is made that if required, this work will be accomplished through a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

4.3.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

4.3.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

4.3.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by

Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor's Capability to Acquire Real Estate is at Exhibit "B" to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

4.3.7 Government Owned Property

There are approximately 34 Government owned parcels within the footprint of the project proposed for acquisition in Jackson County. Most of these lands are within wildlife preserves. Three parcels appear to have improvements. Ownership is listed in public records as United States of America. Specific impacts to Government owned lands and/or structures will be determined during PED.

4.3.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

4.3.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

4.3.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

4.3.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 1,047 relocations in Jackson County. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential

relocations is unknown. The availability of decent safe and sanitary housing is a potential problem. Large scale construction of new residences will most likely be required. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

4.3.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

4.3.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

4.3.14 Estates for Proposed Project

All lands acquired in the buy-out area will be acquired in Fee Simple. The Temporary Work Area Easement will be used for a disposal site if required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

4.3.15 Real Estate Estimate

The real estate cost estimate at Table 4.3.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a disposal site. The requirement, if any, for a disposal site will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

4.3.16 Summary of Potential Real Estate Issues

In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

If the nonstructural acquisition measure is approved, additional time would need to be allowed for staffing up to handle the increased workload for the large number of acquisitions.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

The availability of decent safe and sanitary housing is a potential problem. Large scale construction of new residences will most likely be required.

4.3.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 4.3.17-1 shows the CWBS for real estate activities.

Table 4.3.17-1.
Chart of Accounts - Jackson County Acquisitions

01A	Project Planning	Federal	Non-Federal	Totals
	Other			
	Project Cooperation Agreement

	Rounded			**775,345,000**

CHAPTER 5. ECOSYSTEM RESTORATION

The Environmental Recommended Plan proposes the construction of two (2) pilot projects at Turkey Creek in Harrison County, and Bayou Cumbest in Jackson County. The restoration will consist of restoring emergent tidal marsh habitat and wet pine savannah habitat. These two pilot projects give a basis for future environmental restoration sites identified to be developed. The Comprehensive Plan envisions the construction of environmental restoration projects that would ensure preservation of fish and wildlife, prevent saltwater intrusion, and provide stabilization of the State of Mississippi's shorelines, in order, to reduce or eliminate coastal erosion and restore lost fish and wildlife habitat by identifying degraded critical components of the vital coastal system. It is important to note that ecosystem restoration sites were chosen in areas where environmental restoration can be performed and at the same time reduce risk of future damages to property by acquisition.

5.1 Harrison County Turkey Creek

Figure 5.1-1 identifies areas recommended for environmental restoration in Harrison County. Should all proposed areas be restored, approximately 1,259 parcels with 251 structures would be impacted at a projected acquisition cost of $223,357,000. This REP however, focuses on the pilot project at Turkey Creek.

Figure 5.1-1. Location of Restoration Sites in Harrison County

5.1.1 Project Description

The project site is located north of Gulfport, Mississippi, adjacent to U.S. highway 49, a major north-west thoroughfare, and within the Turkey Creek watershed. The area is becoming increasingly urbanized and development pressures are resulting in increased wetland degradation and loss by the direct filling. The project site as shown in Figure 5.1.1-1 is comprised of 689 acres south (pink border) of the existing railway located on top of an elevated berm. Approximately 190 acres are located north (yellow border) of the railway and functions separately. The combined areas are referred to as Option A, the south area is referred to as Option B, and the north area is referred to as Option C. The site is primarily comprised of a degraded pine savannah wetland. Several miles of ditches have been excavated throughout the site. Additionally the elevated railway berm fragments the wetland habitat and substantially alters the hydrology of the wetlands located to the north. As the areas are undeveloped, no demolition of structures is required. Objectives are to restore native vegetation, restore natural hydrology, restore fish and wildlife habitat, and provide storm water storage protection. The plan calls for mandatory buy-out of lands within the area.

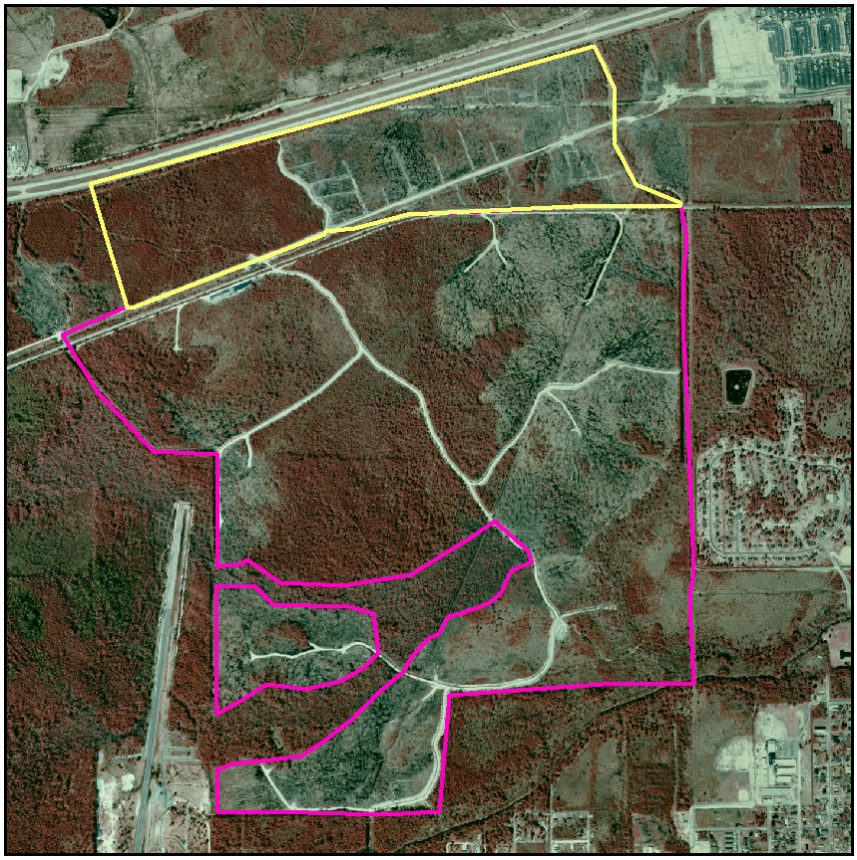

Figure 5.1.1-1. Turkey Creek, Harrison County

5.1.2 Real Estate Requirements

Real Estate requirements for the Turkey Creek Ecosystem Restoration Site in Harrison County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire in fee simple approximately 13 impacted parcels for Option A, 8 parcels for Option B or 5 parcels for Option C. There are no known structures. No other real estate requirements are known at this time.

EP 1165-2-502, paragraph 7 (m.) states that as a general rule, land value should not exceed 25 percent of total project costs for ecosystem restoration, and that proposals consisting primarily of land acquisition are not appropriate as Civil Works ecosystem restoration investments. This project proposes to reduce risk from future hurricane and storm events and to restore the environment. These are two major objectives of the comprehensive plan. The estimated land value is within 25 percent of the estimated total project cost.

5.1.3 Utility/Facility Relocation

Specific information about relocation of utilities/facilities is unknown at this time. An assumption is made that if required, this work will be accomplished under a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

5.1.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

5.1.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

5.1.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

5.1.7 Government Owned Property

There are no known Government owned lands within the proposed project.

5.1.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

5.1.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

5.1.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

5.1.11 Public Law 91-646, Relocation Assistance Benefits

Not applicable.

5.1.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

5.1.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to

advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

5.1.14 Estates for Proposed Project

All lands acquired in the buy-out area will be acquired in Fee Simple.

FEE.

The fee simple title to (the land described in Schedule A) I/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

5.1.15 Real Estate Estimate

The real estate cost estimates at Tables 5.1.15-1 through 5.1.15-3 include the land cost for acquisition of land and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

5.1.16 Summary of Potential Real Estate Issues

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

5.1.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Charts of Accounts at Tables 5.1.17-1 through 5.1.17-3 show the CWBS for real estate activities.

5.2 Jackson County Bayou Cumbest

Figure 5.2-1 identifies the areas recommended for environmental restoration in Jackson County. Should all proposed areas be restored, approximately 2,402 parcels with 658 structures would be impacted at a projected acquisition cost of $335,009,000. This REP however, focuses on the pilot project at Bayou Cumbest. This area is subject to an ongoing Federal Emergency Management Agency (FEMA) Hazard Mitigation Grant Program (HMGP) to Mississippi Emergency Management Agency (MEMA) and Jackson County to acquire all those repetitively flooded properties in the Bayou Cumbest community. Separate discussion with MEMA indicates they will also acquire properties that do not meet the repetitively flooded criteria to avoid a "piece-meal" acquisition pattern. This activity is currently ongoing with or without the MsCIP. Coordination with MEMA indicated that environmental restoration of the area would be an allowable activity but that FEMA would not provide resources to accomplish restoration. Figure 5.2.1-1 shows those parcels in red acquired through the HMGP. It is important to note that as per Engineer Circular 1105-2-218, paragraph 9. Real Estate Crediting Considerations, dated October 1, 2000, "Where use of lands acquired with HMGP funds for a Corps project is consistent with such policies and procedures, and such lands are provided by the non-Federal sponsor for the Corps project, the non-Federal sponsor shall not receive credit toward its required contribution for the value of such lands or any interests therein.. The non-Federal sponsor also shall not receive credit for incidental costs of acquiring lands provided for the Corps project that were paid with HMGP funds. Similarly, the value of such lands, including incidental costs, shall not be included as part of total project costs for cost sharing or NED plan determination."

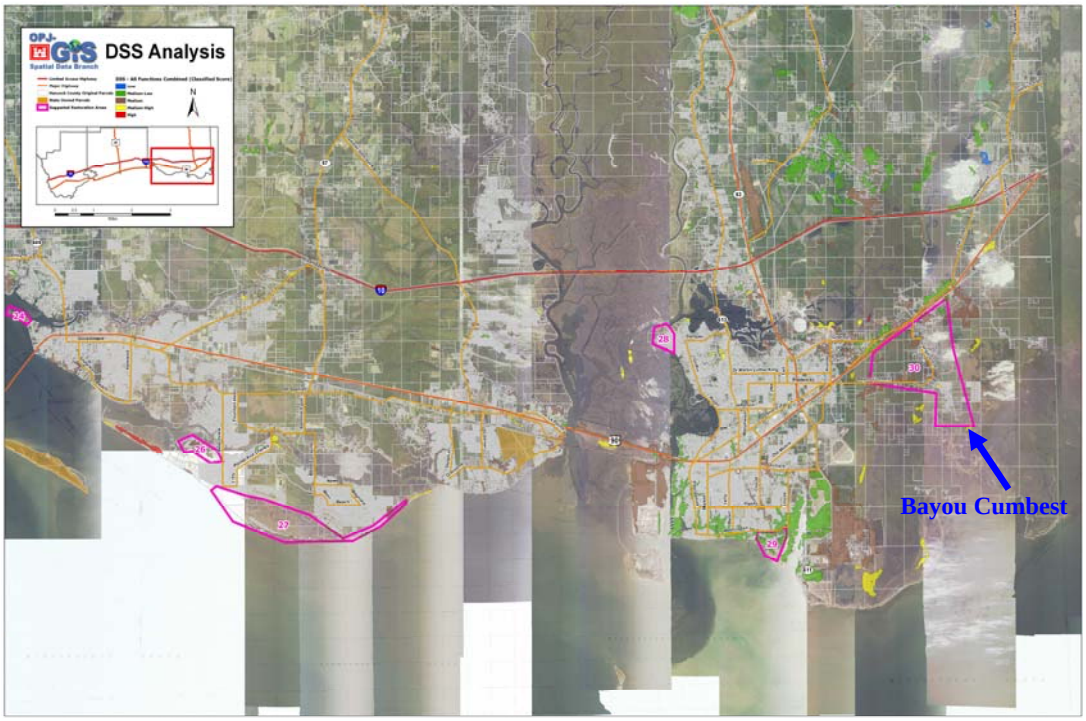

Figure 5.2-1. Location of Restoration Sites in Jackson County

5.2.1 Project Description

The Bayou Cumbest restoration area contains approximately 148 acres of which 110 acres would be restored to emergent tidal marsh and the remaining 38 acres would remain scrub/shrub wetland habitat. The area is shown in Figure 5.2.1-1. The area presently consists of previously filled areas, some tidal marsh and scrub shrub. Objectives are to restore marsh to historical (pre-development ~1950's) conditions, provide storm surge protection, restore native tidal wetland plant community, provide fish and tidal wildlife habitat, and prevent saltwater intrusion. The plan calls for mandatory buy-out of land and 100% removal of existing structures in the area.

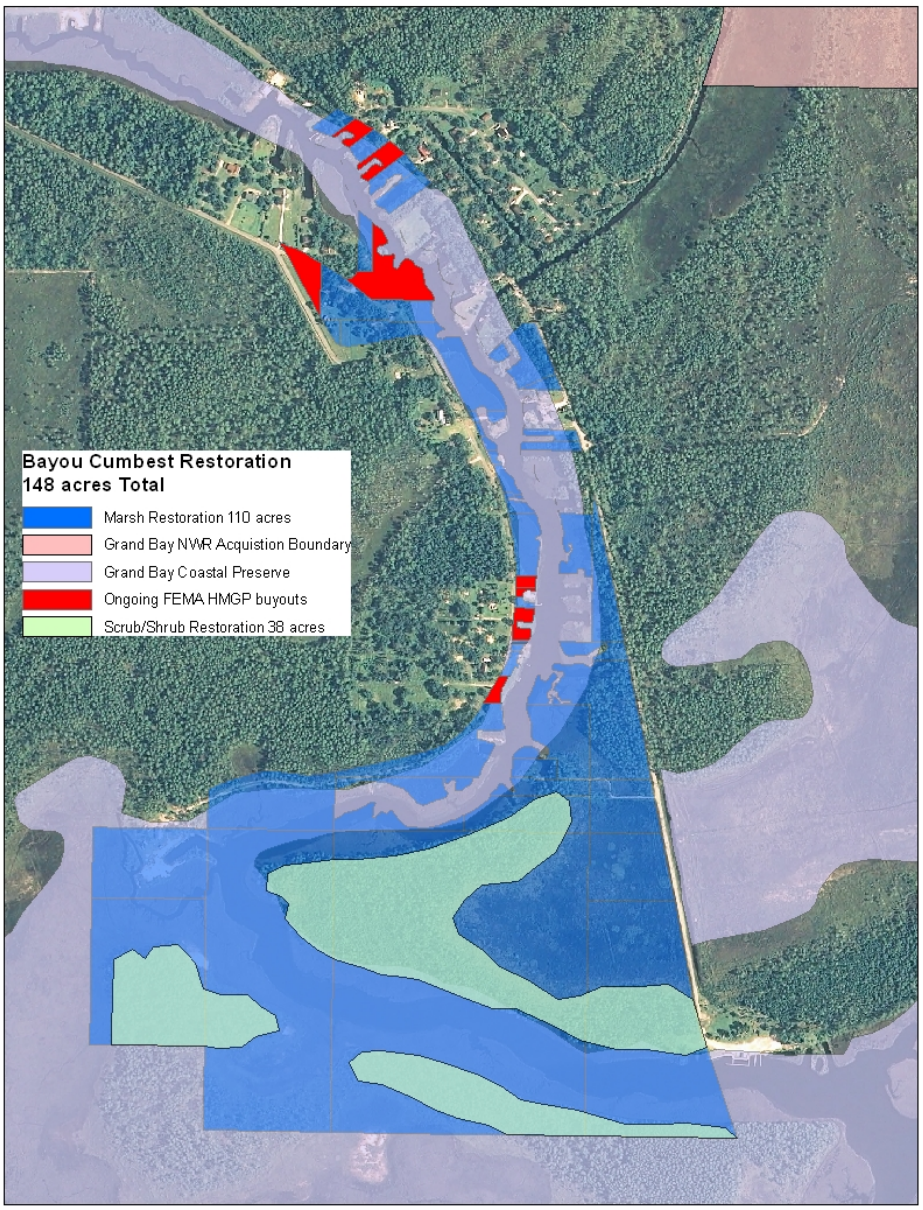

Figure 5.2.1-1. Bayou Cumbest Jackson County

5.2.2 Real Estate Requirements

Real Estate requirements for the Bayou Cumbest Ecosystem Restoration Site in Jackson County include lands, easements, rights-of-way and relocations, and disposal/borrow areas (LERRD), and the right to acquire in fee simple approximately 61 impacted parcels and 19 structures. Based on the

number of structures being impacted, the assumption is that there will be 19 relocations to include residences and businesses. The plan calls to use “approved landfills” for disposal of the demolished structures. An assumption is made that the excavated material will be disposed of in commercial or county landfills. In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

EP 1165-2-502, paragraph 7 (m.) states that as a general rule, land value should not exceed 25 percent of total project costs for ecosystem restoration, and that proposals consisting primarily of land acquisition are not appropriate as Civil Works ecosystem restoration investments. This project proposes to reduce risk from future hurricane and storm events and to restore the environment. These are two major objectives of the comprehensive plan. The estimated land value is within 25 percent of the estimated total project cost.

5.2.3 Utility/Facility Relocation

Specific information about relocation of utilities/facilities is unknown at this time. An assumption is made that if required, this work will be accomplished under a relocation contract. This will be further investigated and confirmed during PED. See Chapter 2 Section 2.10 for more detailed discussion.

5.2.4 Existing Projects/Studies

Relevant projects and studies are found in the main report at Section 1.6, History of the Investigation and Section 1.7, Prior and On-Going Studies, Reports and Programs.

5.2.5 Environmental Impacts

See the Main Report, Chapter 6. Environmental Effects of Plans and the Environmental Appendix, for a full discussion on environmental effects.

5.2.6 Project Sponsor Responsibilities and Capabilities

The State of Mississippi will be the non-Federal Project Sponsor (NFS). The NFS has the responsibility to acquire all real estate interests required for the Project. The NFS shall accomplish all alterations and relocations of facilities, structures and improvements determined by the government to be necessary for construction of the Project.

Title to any acquired real estate will be retained by the Project Sponsor and will not be conveyed to the United States Government. Prior to advertisement of any construction contract, the NFS shall furnish to the government an Authorization for Entry for Construction (Exhibit “A” to the Real Estate Appendix) to all lands, easements and rights-of-way, as necessary. The NFS will also furnish to the government evidence supporting their legal authority to grant rights-of-way to such lands. The NFS shall comply with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, approved 2 January 1971, and amended by Title IV of the Surface Transportation Uniform Relocation Assistance Act of 1987, Public Law 100-17, effective 2 April 1989, in acquiring real estate interests for the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said Act(s). A form for the Assessment of the Non-Federal Sponsor’s Capability to Acquire Real Estate is at Exhibit “B” to the Real Estate Appendix. The assessment will be made during PED phase.

The non-Federal sponsor is entitled to receive credit against its share of project costs for the value of lands it provides and the value of the relocations that are required for the project. Generally, for the purpose of determining the amount of credit to be afforded, the value of the LER is the fair market value of the real property interest, plus certain incidental costs of acquiring those interests, that the non-federal sponsor provided for the project as required by the Government. The NFS cannot receive credit for the value of any LER, including incidental costs, which were previously provided as an item of cooperation for another Federal project, including projects that preceded enactment of WRDA 1986.

5.2.7 Government Owned Property

There are no known Government owned lands within the proposed project.

5.2.8 Historical Significance

See the Main Report, Section 3.2.9 Cultural and Archaeological Resources, for a general discussion on cultural and archaeological resources.

5.2.9 Mineral Rights

There are no known mineral activities within the scope of the proposed project.

5.2.10 Hazardous, Toxic, and Radioactive Waste (HTRW)

Due to the extent of the project, no preliminary assessment was performed to identify the possibility of hazardous waste on the sites. These studies will be conducted during the next phase of work. See Sections 3.2.8 and 6.16 of the Main Report for a discussion on HTRW.

5.2.11 Public Law 91-646, Relocation Assistance Benefits

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 establishes a uniform policy for fair and equitable treatment of persons displaced as a result of federal and federally assisted programs in order that such persons shall not suffer disproportionate injuries as a result of programs designed for the benefits of the public as a whole. A qualified displaced person may be entitled to certain relocation assistance benefits which include reimbursement of moving costs and a replacement housing benefit. Moving expense can be reimbursed either based on actual costs or a fixed moving cost schedule. The replacement housing payment is separated into 3 basic types - purchase supplement, rental assistance and down payment. All replacement housing must be decent, safe, and sanitary (DSS) before a replacement housing payment can be made.

It is estimated that there are approximately 19 relocations in Bayou Cumbest Ecosystem Restoration Site area. No relocation plan has been completed nor has a relocation survey been done. All estimates are based on information from county public records. The number of business relocations as compared to residential relocations is unknown. The availability of decent safe and sanitary housing may be a potential problem. In order to accomplish the relocation activity in a timely manner, the plan set forth in Chapter 2. Section 2.5 can be used.

5.2.12 Attitude of Property Owners

Real Estate has not interviewed property owners or tenants during the study phase for the MsCIP. However, numerous public meetings have been held at different locations throughout the study area

to inform stakeholders and property owners about the study and the protective measures under consideration for the Mississippi coastal area. A number of local newspapers have published articles that discuss the MsCIP study and the perceived positive effects as well as the negative impacts that may occur as a result of the project. Some of these articles can be found on web sites. While many of the locals may welcome the benefits of the proposed project, there are some who oppose the project.

5.2.13 Acquisition Schedule

An acquisition schedule will be developed when plans and specifications become available and more definite information is available pertaining to the specific areas and number of parcels for acquisition. The acquisition schedule will be developed during PED and will be a joint effort of the NFS, the project manager and Real Estate. The schedule will set forth a time line for title, survey, appraisal, negotiation, preparation of documents and closing activity. After acquisition activity is completed certification of lands acquired/owned by the sponsor will be necessary prior to advertisement for construction. The Certification of Real Estate can be accomplished within 30 - 60 days after acquisition. See Chapter 2. Section 2.5. for discussion on an acquisition implementation/management plan.

5.2.14 Estates for Proposed Project

All lands acquired in the buy-out area will be acquired in Fee Simple. The Temporary Work Area Easement will be used for a disposal site if required. The estates recommended are standard estates.

FEE.

The fee simple title to (the land described in Schedule A) l/(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

TEMPORARY WORK AREA EASEMENT.

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date possession of the land is granted to the Project Sponsor, for use by the Project Sponsor, its representatives, agents, and contractors as a work area, including the right to deposit backfill, move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the _____ Project, together with the right to trim, cut, fell and remove there from all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

5.2.15 Real Estate Estimate

The real estate cost estimate at Table 5.2.15-1 includes the land cost for acquisition of land, relocation benefits to include a replacement housing payment and fixed rate move expenses, and Federal and non-Federal administrative costs. Administrative costs are those costs incurred for verifying ownership of lands, certification of those lands required for project purposes, legal opinions, analysis or other requirements that may be necessary, during PED. No cost is included for a

disposal site. The requirement, if any, for a disposal site will be identified during PED. If further real estate requirements are identified during PED or if there is a significant increase in cost, a supplement to the Real Estate Appendix will be prepared. A 25% contingency is applied to the current estimate.

5.2.16 Summary of Potential Real Estate Issues

In the event that the excavated material is not suitable for a landfill a disposal site will have to be acquired. Typically if disposal sites are required, this would be considered as part of the LERRD requirement. Real Estate would provide an analysis during PED to compare the cost of acquiring an upland disposal site with the cost of using a commercial landfill and make a determination which method is most cost effective.

Any requirements for relocation contracts pertaining to facilities/utilities will be identified and completed during PED.

Should condemnation of any required real estate interest be necessary, it is the responsibility of the NFS. This issue is addressed during the Assessment of the Non-Federal Sponsor's Real Estate Acquisition Capability. However, if the real estate interest is one that the NFS does not have authority to condemn, the Federal Government can perform the condemnation on behalf of the NFS.

A relocation plan will need to be completed during PED to address potential relocation activity under P.L. 91-646. There are a number of factors pertaining to relocations that can impact the project both in cost and in schedule. Payments for Housing of Last Resort, which would exceed the standard housing replacement payments, are very likely due to the size of the project and the lack of available

decent, safe and sanitary housing in the area. Another factor that could increase cost and impact schedule is the cost of business relocations. Depending on the type of business and the operation, this could involve moving equipment and machinery to new locations. It is necessary to interview each impacted individual and business during Pre-Construction, Engineering and Design Phase to determine the requirements for relocation and to estimate a cost for the relocation.

The availability of decent safe and sanitary housing may be a potential problem.

5.2.17 Chart of Accounts

The cost estimate for all Federal and non-Federal real estate activities necessary for implementation of the project after completion of the feasibility study for land acquisition, construction, LERRD, and other items are coded as delineated in the Cost Work Breakdown Structure (CWBS). This real estate cost estimate is then incorporated into the Total Current Working Estimate utilizing the Microcomputer Aided Cost Engineering System (MCACES). The Chart of Accounts at Table 5.2.17-1 shows the CWBS for real estate activities.

Assessment of Non-Federal Sponsor's

Real Estate Acquisition Capability

I. Legal Authority:

a. Does the sponsor have legal authority to acquire and hold title to real property for project purposes? (yes/no)

b. Does the sponsor have the power to eminent domain for this project? (yes/no)

c. Does the sponsor have "quick-take" authority for this project? (yes/no)

d. Are any of the land/interests in the land required for this project located outside the sponsor's political boundary? (yes/no)

e. Are any of the lands/interests in land required for the project owned by an entity whose property the sponsor cannot condemn? (yes/no)

II. Human Resource Requirements:

a. Will the sponsor's in-house staff require training to become familiar with the real estate requirements of Federal projects including P. L. 91-646, as amended? (yes/no)

b. If the answer to II.a. is "yes", has a reasonable plan been developed to provide such training? (yes/no)

c. Does the sponsor's in-house staff have sufficient real estate acquisition experience to meet its responsibilities for the project? (yes/no)

d. Is the sponsor's projected in-house staffing level sufficient considering its other work load, if any, and the project schedule? (yes/no)

e. Can the sponsor obtain contractor support, if required in a timely fashion? (yes/no)

f. Will the sponsor likely request USACE assistance in acquiring real estate? (yes/no)

III. Other Project Variables:

a. Will the sponsor's staff be located within reasonable proximity to the project site? (yes/no)

b. Has the sponsor approved the project/real estate schedule/milestones? (yes/no)

Exhibit B
1st page

IV. Overall Assessment:

a. Has the sponsor performed satisfactory on other USACE projects? (yes/no/not applicable)

b. With regard to the project, the sponsor is anticipated to be: highly capable/fully capable/moderately capable/marginally capable/insufficiently capable.

V. Coordination:

a. Has this assessment been coordinated with the sponsor? (yes/no)

b. Does the sponsor concur with this assessment? (yes/no) (If "no", provide explanation)

MISSISSIPPI COASTAL IMPROVEMENT PROGRAM (MsCIP)

High Hazard Area Risk Reduction Plan
Phase I

29 January 2009

Exhibit "C"

Real Estate Summary

This report addresses a nonstructural plan for the purchase of approximately 15,000 parcels located in the high hazard zones of the three coastal counties of Mississippi. This tentatively selected plan would be implemented under two phases. Phase I referred to as the High Hazard Area Risk Reduction Plan (HARP) would include the purchase of approximately 2,000 parcels over the next five years. The second phase or Phase II of the HARP would be for purchase of an estimated 13,000 parcels and would include floodproofing of structures as part of a comprehensive long term risk reduction plan coordinated between HUD, FEMA and the Corps.

The sheer magnitude of the devastation, together with the number of residential homeowners still displaced more than three years after Hurricane Katrina, presents unprecedented challenges and opportunities. Acquisition of properties where the residential owner has not yet rebuilt and continues to be displaced, presents a unique window of opportunity to minimize cost.

1. STUDY Authority/Background

The Mississippi Coastal Improvements Program, Hancock, Harrison, and Jackson Counties, Mississippi (MsCIP) and the MsCIP Comprehensive Plan Report was authorized for study by the Department of Defense Appropriations Act, 2006 (P.L. 109-148) 30 December 2005. The authorization was in response to numerous deaths, extensive damage to environmental resources, homes, businesses and industries, exacerbated saltwater intrusion problems, widespread coastal erosion, damage to public infrastructure and the regional economy caused by the Hurricanes of 2005.

During the study, based upon Corps of Engineers' data, FEMA damage estimates, State of Mississippi post-Katrina reports and on-site Corps investigations, a visually distinct zone was identified in which all residential and commercial structures were destroyed or so significantly damaged as to deny re-occupation. A majority of residential and commercial structures within the "high-hazard zone" (see Figures 1 – 4) designated by the Corps were destroyed and have not yet been rebuilt. The rebuilding rate within the inundated area and in particular the high-hazard zone has been much slower than might typically be expected following a hurricane.

The comprehensive plan developed by the study team, resource agencies and public contains a recommendation for the implementation of a significant non-structural alternative for the acquisition and/or floodproofing of properties within the area identified as having a 1 percent annual chance of inundation from hurricane and storm surges, with the goal of reconstructing the project area as a disaster-resilient community. A portion of this area, designated the high-hazard zone, is regarded as too dangerous for certain types of nonstructural measures that would place a residential structure (using normal building code construction practices), even an elevated residential structure, in the pathway of the surge and waves from a Katrina-like storm. Therefore the high-hazard zone is not considered an appropriate location for floodproofing by elevation while permanent acquisition of properties and removal of structures from that zone is considered an appropriate measure. To implement this component of the 1% annual chance plan the study team formulated an approach referred to as the High Hazard Area Risk Reduction Plan (a.k.a. the HARP).

The nonstructural component of the comprehensive plan is to acquire or floodproof all properties within the 1 percent annual chance inundation zone commonly referred to as the '100-yr' floodplain. This equates to an estimated 58,000 parcels of which an estimated 15,000 parcels are within the high hazard zone. Obviously it is not realistic to consider that this action could be undertaken within a short timeframe due to impacts on local tax base, ability to acquire etc. It is more realistic to consider that the component could be phased in over an extended multi-year period. For this reason phased implementation was developed including a floodproofing demonstration, a municipal acquisition and relocation project, a high hazard area risk reduction plan or HARP, and a comprehensive long-term risk reduction plan coordinated between HUD, FEMA and the Corps. The HARP would address approximately 2,000 parcels in the most high risk areas that are not suitable for floodproofing that could be implemented over a five year period. The long-term risk reduction plan is envisioned as a coordinated effort between HUD, FEMA, and the Corps to be applied over a much longer period and would include acquisition of additional parcels, floodproofing of existing structures and designated elevation requirements for new structures. In order to maximize benefits under the HARP, the plan would be implemented in the most high risk areas first and, initially, with owners who are still displaced and willing to sell. However, eminent domain may be used when warranted.

2. Advantages

There are significant advantages to an acquisition plan for residential and other properties within the high risk zones of coastal Mississippi. An acquisition plan utilizing the application of constructive occupancy for these parcels would:

- Reduce future property loss and potential loss of life.
- Eliminate costly structural alternatives and associated long term operation and maintenance costs.
- Provide a buffer and aid in reducing storm surge to adjoining properties.
- Provide an opportunity as lands are acquired both now and in the future to initiate alternative uses of these lands for fish and wildlife preservation, ecosystem restoration and public recreation and other compatible public uses.

There are substantial additional benefits that can be attained with an expeditious authorization of the HARP and the near-term benefits could significantly be reduced or lost should the program not be authorized until a later date.

- Prompt initiation of acquisition is more cost effective to the Government than commencing acquisition several years hence. Acquisition prior to rebuilding also avoids displacement impacts which increase significantly after residents have rebuilt.
- Near-term acquisition will reduce requirements for other Government-assisted temporary housing programs for those owners that are still displaced, and may continue to receive financial assistance from the State or Federal Government.

3. Schedule

Under Phase 1 of the HARP, it is proposed that approximately 2,000 of the estimated 15,000 parcels identified in the high hazard zones of the three coastal counties of Mississippi be acquired from those owners who are still displaced and are willing to sell.

When identifying the acquisition process and steps for a HARP based on the acquisition of an estimated 2,000 parcels, the total time required was estimated to take approximately five (5) years. The HARP acquisition process should require less administrative time and related costs as a traditional acquisition since the traditional survey of the entire project area would not be required and the time spent for negotiations would be minimal due to initially acquiring parcels from owners willing to sell. Additionally, the administrative cost associated with the legal requirements for processing condemnations should not be necessary or minimal.

Considering that many of the estimated 15,000 parcel owners may not participate in an acquisition program and that many may not be eligible for other reasons, the MsCIP Project Delivery Team estimated that approximately 2,000 of these property owners would likely sell their parcel under a HARP. An estimate of 400 parcels per year based on a five (5) year program would be a reasonable number of acquisitions to expect with an adequately staffed office.

4. Costs

Because of the uncertainties regarding the number of parcels that may remain vacant at the time of acquisition, the value of any new improvements, and the applicability of occupancy requirements under a typical relocation program, the following Tables indicate the estimated range of cost that may be incurred with implementing a Phase I HARP with and without a RHP.

Table 1
HARP Costs Without RHP

For Acquisition of Approximately 2,000 Parcels

Number Parcels	Vacant Parcel Value	Structure Value	91-646 Payment	Demolition Costs	Acq.Cost Admin	Total Acquisition Cost
2,000 vacant	100,000,000	0	0	0	$50,000,000	$150,000,000 *

* Note: Total with contingencies would be $187,500,000.

Table 2

HARP Cost With Use of RHP

For Acquisition of Approximately 2,000 parcels

Number Parcels Occupied Pre-K	Vacant Parcel Value	RHP Payment	Less Other Payments Ins/Grants	91-646 Payment (moving)	Demolition Costs	Acquisition Admin Costs	Total Acquisition Cost
2,000 Vacant	100,000,000	360,000,000	180,000,000	5,000,000	0	50,000,000	$335,000,000 *

* Note: Total with contingencies would be $397,000,000.

5. Application of the Uniform Relocation Assistance and Real Property Acquisition Policy Act of 1970, as Amended (URA)

The URA for the acquisition of real property provides various benefits to property owners when their property is acquired for an authorized Federal project. In keeping with the vision of the MsCIP for establishing a disaster-resilient coastline in regards to hurricane and storm surge, any benefit payments such as a Replacement Housing Payment (RHP) under the proposed HARP would be subject to the property owner establishing occupancy in decent, safe and sanitary (DSS) housing outside the designated high-hazard zone. Depending on the flood zone criteria for the area that the owner relocates to, the DSS designation would include the necessity to elevate the first floor of the home in accordance with the new Digital Flood Insurance Rate Map (DFIRM).

6. Replacement Housing Payment (RHP) Under the URA

Eligibility for relocation benefits under the URA is triggered generally by the occurrence of one of the following actions taken by the Federal Government or by a non-Federal sponsor for a Federally assisted project: (1) the initiation of negotiations, (2) the issuance of a notice of intent to acquire, or

(3) the actual acquisition of the property, whichever comes first. Generally, persons otherwise eligible under the URA requirements who move from their property, or move personal property, as a direct result of these displacing activities are considered displaced persons covered by the URA. One benefit under the URA available to eligible displaced persons of residential properties is payment of a RHP. Such a payment would be in addition to the payment of the fair market value for the land itself.

Because many of the residential owners of the HARP Phase 1 parcels displaced by Hurricane Katrina may not occupy the property when the acquisition phase of the project is commenced, the potential for application of a "constructive residential occupancy" theory under the URA and its implementing regulation contained in 49 CFR Part 24 is being evaluated as a means to provide a RHP for residents who otherwise meet eligibility requirements under the URA.

7. Acquisition Implementation and Management Plan

Specific guidelines for deployment of a HARP should be developed as a part of the authorization process and should be utilized to implement and manage the HARP. Preparation of an Acquisition Implementation and Management Plan (AIMP) in coordination with the Project Sponsor would ensure successful implementation and management of the HARP. The AIMP should be utilized and updated throughout the acquisition program as a working document and should include acquisition schedules, real estate costs, budgets, processes, a relocation plan, program eligibility requirements, contacts, notification letters, applicable state and federal laws, defined acquisition areas, parcels identified for acquisition, prioritizing of parcels for acquisition, appraisal and comparable housing data, closing processes and any other relevant issues. To facilitate the acquisition process, it is recommended that a Draft AIMP be initiated as soon as possible and prior to a HARP implementation.

8. Other Federal Disaster Assistance Programs in Coastal Mississippi

There are at least two other significant post-Katrina Federal programs currently operating within the communities of the project area. Both the Federal Emergency Management Agency (FEMA) and the US Housing and Urban Development Administration (HUD) have ongoing programs within the project area that are designed to reduce future damages or to compensate landowners for damages.

9. FEMA Assistance Programs

FEMA has been operating several post-Katrina programs designed to compensate landowners for storm-related damages, reconstruct and repair damaged structures and reduce future flood damages and loss of life due to hurricane surge and other storm-related threats. FEMA administers the Individual Assistance Program (IAP), Public Assistance Program (PAP), Other than Housing Needs Assistance Program, Debris Removal Program, Temporary Housing Program and the Hazard Mitigation Grant Program within the project area. Each of these programs is administered locally by The Mississippi Emergency Management Agency (MEMA). To date over 350,000 individuals and families have been helped by the assistance programs. Most of these grant programs cover losses or needs over and above any flood insurance payments that may be available to the landowner and the grants are provided tax-free.

The individual assistance program provides grant funds to individuals and families for temporary housing, and the repair, replacement or reconstruction of homes damaged by Katrina. Those repairs

must be made in conformance with NFIP requirements according to the local floodplain management ordinances and the funds do not cover losses to second or vacation homes in the project area. This disaster assistance program is implemented under the Individuals and Households Program (IHP) and provides grant assistance for re-establishment of households in the affected areas. Opportunities for applying flood damage mitigation measures to damaged homes are encouraged by FEMA administrators but for those landowners without flood insurance, but receiving disaster assistance, the mitigation measures are optional. Additional long-term recovery funding can be provided through low-interest loans from the Small Business Administration.

As of April 2008, over 200,000 individuals and families have received Housing Assistance payments and over 130,000 have received Other Needs Assistance grants. Total payments to these two components of the FEMA assistance program have reached $1.2 billion to date. In addition, more than $2.8 billion has been obligated by FEMA in their Public Assistance program helping to reconstruct public buildings and facilities, utilities, roads and bridges and recreation facilities.

The Hazards Mitigation Grant Program is also being administered in the project area through the Mississippi Emergency Management Agency (MEMA). This program provides grant funds to address flood damages for structures and property that are subject to repetitive flooding or were damaged by Katrina and had been identified for acquisition in the state All-Hazards Mitigation Plan. Projects must show savings greater than costs. Some of the activities that can be implemented under the HMGP to protect either public or private property from future flood damages are:

1) Acquisition of property or relocation of buildings to convert the property to open space use

2) Retrofitting structures to minimize damages from high winds, flood, or other hazards

3) Elevation of flood prone structures

4) Development and initial implementation of vegetative management programs

5) Minor flood control projects that do not duplicate the activities of other Federal agencies

6) Localized flood control projects, such as ring levees and floodwalls designed specifically to protect critical facilities

7) Post-disaster building code activities that support code officials during the reconstruction process

10. HUD Assistance Programs

The Homeowner Assistance Grant Program (a.k.a. HAP) is a disaster recovery program being implemented through the Mississippi Development Authority for those areas specifically damaged by Katrina hurricane surge inundation. The program is generally available to low to moderate income households (up to 120% of the median household income) with limited funding for higher-income households. The program is being implemented in two phases – Phase 1 for those structures located outside the 100-year flood zone established in the FIRM but were flooded by the Katrina surge and Phase 2 for those structures damaged by hurricane surge and located within the 100-year flood zone mapped in the FIRM.

The program has two components. The first component is a compensation grant of up to $150K (phase 1) to compensate homeowners for losses to single-family, owner-occupied duplexes or mobile homes due to flooding by surge that were not covered by insurance. The percentage of the total grant available is dependent upon the insured value of the home times the percentage of damage determined in a damage assessment. Homeowners may repair, replace or reconstruct

homes as they choose with the funds. No local permits for home repair or construction or evidence of the use of the funds for those purposes is required by HUD or MDA. Homeowners must comply with NFIP requirements for elevating the structure and may apply for the second component of the program – the elevation grant (see description in Section 11) – to defray the costs of elevating the home. In phase 2 of the HAP, the compensation grant amount is limited to $100K.

The second component of the HAP is the elevation grant and is available to homeowners who did not have flood insurance through the NFIP. Section 11 has more discussion of this elevation program through HUD.

Neither the compensation grant program nor the elevation grant program restricts any homeowner from rebuilding a destroyed or substantially damaged structure or elevating a damaged/repaired structure in the new DFIRM-designated V or VE zone. The only requirements are compliance with current NFIP guidelines as described in local floodplain management ordinances and current building codes. Any structure being elevated under either program would be raised to the new BFE established in the DFIRM flood zone mapping. This new BFE may be lower than the surge elevation that came ashore with Katrina in some areas. Residual damages during a recurrence of a Katrina-like storm as a result these elevation and compensation programs could be significant.

As of May 15, 2008, the HAP has received 19,401 applications for Phase 1 and 8,534 for Phase 2 of the program and has distributed grant funds to 20,437 of those applicants totaling more than $1.4 billion.

In addition to the Homeowners Assistance Program discussed above, the MDA is implementing, through the HUD Community Development Block Grant (CDBG) program, the Long Term Workforce Housing Program. The purpose of this program is to provide grants and loans for local jurisdictions, non-profits and for-profit organizations to provide long-term affordable housing in the three coastal counties and Pearl River County. These funds can be used to repair, rehabilitate, or reconstruct housing units for low and moderate income families and must include at least 40 dwelling units for each grant or loan request. The program projects that as many as 5,800 housing units may be created in these four counties with only local building code and NFIP restrictions.

11. Non-Corps Federal Floodproofing Programs

Following the rescue and recovery operations in the project area, both FEMA and the HUD entered the damaged Gulf areas and began to implement assistance (grant and loan) programs. Each of the two agencies has been offering floodproofing (or elevation) grants to eligible landowners so that homes, businesses and public structures could be elevated to reduce future damages.

FEMA has been providing elevation grants ($30K) to eligible landowners so that either new construction or retro-fitted homes could be elevated in accordance with the NFIP and local floodplain management ordinances. The grant would be in addition to any flood insurance payments that an insured property owner may have received. The elevation requirements specify the base flood elevation (BFE) or the Advisory Base Flood Elevation (ABFE), whichever is the best available data at that time. Regardless of the specified BFE elevation used to site the first floor of the structure, there are no restrictions in the FEMA elevation grant program to elevating homes in the newly-mapped V or VE zone. Other than any building code requirements of the municipal or county area or restrictions included in the local floodplain management ordinances, elevating structures in the mapped V or VE zone is allowed under the FEMA assistance program.

Likewise, HUD has an elevation grant program as well that provides $30K to eligible landowners to assist in raising the first floor of either a new home or a retro-fitted home to reduce future flood damages. The $30K grant helps to defray the cost of elevating the home and is payable in two

installments - $15K when the elevation permit is obtained and $15K when an occupancy permit is obtained. Neither HUD nor MDA are providing direct oversight for the elevation design or construction processes, but are relying on local NFIP and building code inspectors to assure compliance with the local ordinances. Also similar to the FEMA elevation grants, the HUD program has no restrictions on elevating homes within the V or VE zones shown on the floodplain mapping.

Both of these programs provide grant funds to landowners that assist in elevating their homes, but in many cases the grant may not provide the total amount necessary to cover the entire costs of elevating the structure according to the full requirements of the NFIP or the local building codes (IRC/IBC). When the distance between the ground surface and the BFE is minor (1-3 feet) and the structure is being constructed, the grant may cover the increased costs of the extended foundation, utility lines and additional steps that support, service and access the higher first floor. Normally, the incremental cost of elevating new construction to meet NFIP requirements is less than retro-fitting an existing structure.

Where an existing structure must be retro-fitted with a new foundation or where a new structure must be raised to a higher level (8-15 feet) above the ground surface, the assistance grant will not likely cover the homeowner's full cost. Retro-fitting normally requires much preparatory work beneath the structure (dependent upon the foundation type; slab, crawl space, basement) followed by raising the first floor of the structure to the new design flood height (BFE) and installing new piling or masonry columns beneath the structure. This total cost normally exceeds the elevation grant by a significant amount. Significantly elevating a new structure (10-15 feet) can be quite expensive considering the costs of installing deep pilings, bracing the pilings, construction of extended utilities and providing access to the higher first floor. Any special needs of the household members under the American Disabilities Act (ADA) that require wheelchair ramps or chair lifts can add significantly to these costs.

12. Integration of Corps and Non-Corps Nonstructural Programs

In their implementation, components of the three programs do not mesh well at this time. Redevelopment within the V and VE zones in both the FEMA and HUD programs directly conflicts with the proposed MsCIP plan to offer only permanent acquisition in those areas. In terms of elevation or floodproofing, both the FEMA and HUD programs have no restrictions to floodproofing within the V or VE zone while the MsCIP avoids any floodproofing actions within the V/VE zones.

In addition to the cost differentials between elevation costs (based upon Corps project cost data) and the grant amounts that may surface during implementation of the two programs, the lack of specific guidelines for elevating residential construction within the mapped V and VE zones in the FEMA and HUD programs should be considered. Generally, the base flood elevation to which all new construction or retro-fitted construction included within the FEMA and HUD assistance programs must raise the first habitable floor, may be lower than the hurricane surge that would be expected (and was experienced during Katrina) from a Category 5 hurricane. Hurricane surge depths in Katrina exceeded 25 feet in the V/VE zones of the project area. The number of totally destroyed homes in the V and VE zones that had been elevated in compliance with the pre-Katrina BFE is a testament to the potential for significant residual damages and loss of life that could occur as a result of implementing the two non-Corps elevation grant programs.

The MsCIP plan in comparison, although using the storm events of 2005 and especially Katrina as its benchmark for protection and reducing flood damages and loss of life, would substantially reduce residual damages and threats to public safety.

In terms of financial assistance, the MsCIP is founded on the premise of government-directed construction activities with associated design, regulatory and contracting controls to assure good quality, legality and accountability. Both the FEMA and HUD programs are essentially grants to landowners with minimal or no controls for design quality or accountability (esp. in the HUD compensation program). The MsCIP program costs are founded on the requirements of the Uniform Relocations Act and actual floodproofing/relocations construction costs while the FEMA and HUD programs have set grant limits regardless of the actual costs of the work required.

As stated in Section 24 below, much coordination work needs to be completed between the agencies to assure that these programs can be integrated in a safe and efficient manner so that residents are offered practical and safe options for protecting their lives and property.

13. Project Sponsor Responsibilities and Capabilities

The Non-Federal Sponsor will have the responsibility to acquire all real estate interest required for the Project and perform all relocations determined by the Government to be necessary for the project. The Government will have oversight of these activities and with compliance of PL 91-646.

14. Conclusions

The nonstructural program components discussed above can provide significant levels of risk reduction to the residents and businesses in the project area and can be the foundation for development of a disaster-resilient community along the Gulf Coast. When compared to other flood damage reduction alternatives for the project area the nonstructural components are cost effective, environmentally friendly, incremental in deployment but cumulative in benefit accrual, affordable in terms of local sponsor OMRR&R costs, supportive of local NFIP ordinances, and can be integrated into other community plans for energy conservation, new housing development, economic development, public transit strategies, and renewal of public facilities through local Capital Improvements Programs.

According to a FEMA report dated 4 Dec 08, there have been 40,195 travel trailers and mobile homes deactivated in Mississippi since Katrina of which 3,020 remain in service. Of these units, 1,783 are currently occupied within the three coastal counties. This would suggest that substantial benefits can still be realized from a near term acquisition program.

15. Outstanding Coordination Issues

Continue to petition both FEMA and HUD to obtain the non-Corps assistance application data that would form the basis of further detailed planning for the structural and nonstructural elements of the proposed protection plan. Also, formulate collaborative strategies for integrating the Corps and non-Corps projects/programs within the project area so that residents will get the most benefit from the programs without excessive duplication of Federal effort, missed opportunities for synergistic solutions or misuse of Federal funds.

DRAFT

February 2009

Mississippi Coastal Improvements Program (MsCIP) Hancock, Harrison, and Jackson Counties, Mississippi

Appendix D Non Structural

FOREWORD

This document is one of a number of technical appendices to the Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan and Integrated Feasibility Report and Environmental Impact Statement.

The Mississippi Coastal Improvements Program (MsCIP) Comprehensive Plan Integrated Feasibility Report and Environmental Impact Statement provides systems-based solutions and recommendations that address: hurricane and storm damage reduction, ecosystem restoration and fish and wildlife preservation, reduction of damaging saltwater intrusion, and reduction of coastal erosion. The recommendations contained in the Main Report/EIS also provide measures that aid in: greater coastal environmental and societal resiliency, regional economic re-development, and measures to reduce long-term risk to the public and property, as a consequence of hurricanes and coastal storms. The recommendations cover a comprehensive package of projects and activities that treat the environment, wildlife, and people, as an integrated system that requires a multi-tiered and phased approach to recovery and risk reduction, irrespective of implementation authority or agency.

The MsCIP Study Area

The purpose of the Comprehensive Plan Report is to present, to the Congress of the United States, the second of two packages of recommendations (i.e., the first being the "interim" recommendations funded in May 2007, and this "final" response, as directed by the Congress), directed at recovery of vital water and related land resources damaged by the hurricanes of 2005, and development of recommendations for long-term risk reduction and community and environmental resiliency, within

the three-county, approximately 70 mile-long coastal zone, including Mississippi Sound and its barrier islands, of the State of Mississippi.

This appendix, the Main Report/EIS, and all other appendices and supporting documentation, were subject to Independent Technical Review (ITR) and an External Peer Review (EPR). Both review processes will have been conducted in accordance with the Corps "Peer Review of Decision Documents" process, has been reviewed by Corps staff outside the originating office, conducted by a Regional and national team of experts in the field, and coordinated by the National Center of Expertise in Hurricane and Storm Damage Protection, North Atlantic Division, U.S. Army Corps of Engineers.

The report presents background on the counties that comprise the Mississippi coastline most severely impacted by the Hurricanes of 2005, their pre-hurricane conditions, a summary of the effects of the 2005 hurricane season, problem areas identified by stakeholders and residents of the study area, a summary of the approach used in analyzing problems and developing recommendations directed at assisting the people of the State of Mississippi in recovery, recommended actions and projects that would assist in the recovery of the physical and human environments, and identification of further studies and immediate actions most needed in a comprehensive plan of improvements for developing a truly resilient future for coastal Mississippi.

This appendix contains detailed technical information used in the analysis of existing and future without-project conditions, in the development of problem-solving measures, and in the analysis, evaluation, comparison, screening, and selection of alternative plans, currently presented as tentatively-selected recommendations contained in the Main Report/EIS.

Each appendix functions as a complete technical document, but is meant to support one particular aspect of the feasibility study process. However, because of the complexity of the plan formulation process used in this planning study, the information contained herein should not be used without parallel consideration and integration of all other appendices, and the Main Report/EIS that summarizes all findings and recommendations.

Nonstructural measures are proven methods and techniques for reducing flood damages and loss of life in floodplain and coastal areas threatened by storms and hurricanes. Tens of thousands of structures throughout the coastal fringes of the United States have been protected using nonstructural measures found to be effective in preventing damages, cost effective when compared to other measures and acceptable to the general public. Nonstructural measures can be used as a stand-alone program to create disaster-resilient communities.

Prior to implementation of the proposed comprehensive nonstructural plans discussed herein, more detailed project development plans would need to be prepared in close collaboration with the counties, municipalities, the state and Federal agencies for the project area. In any nonstructural program that spans multiple jurisdictions there would be imbalances in tax revenues as displaced landowners relocated to nearby communities coupled with disparities in public service capabilities and school enrollments. Agreements between jurisdictions concerning lost/gained tax revenues and adjusted public service areas as well as school enrollment adjustments must be considered before initiating a full-scale nonstructural project. In addition, changes in the current flood insurance rate maps, establishment of new base flood elevations and enlargement of the VE zone by FEMA would necessitate revision of the designated zones where certain measures have been specified in this Appendix. All of these ongoing changes would need to be incorporated into more detailed project implementation reports to better estimate costs and potential socioeconomic impacts prior to implementation.

EXECUTIVE SUMMARY

The Mississippi Coastal Improvement Project area contains over 70,000 parcels of property of which a high percentage were, prior to Katrina, occupied by structures. Many of those parcels are now vacant with only slab foundations and FEMA temporary trailers remaining to show where households and businesses once stood. Redevelopment of the project area has been limited due to legal and financial issues with respect to floodplain regulatory determinations and flood insurance payments. Once these issues are resolved, redevelopment of the vacant parcels may accelerate at a feverish pace. The future-without project scenarios of the comprehensive plan contemplate full redevelopment (residential or residential & commercial mix) of the project area by the year 2012 as described in more detail in the Economics Appendix.

The nonstructural PDT, using data from the USACE Mobile District, FEMA, NOAA, county assessor's offices and local sources has formulated nonstructural measures that, working either independently of structural measures or in concert with them, provide substantial reductions in flood damages. Many uncertainties remain in the nonstructural formulation because of the lack of complete structure-specific data. More in-depth planning in collaboration with the counties and municipalities is needed to address the uncertainties regarding the cost efficiency and effectiveness of the nonstructural measures as well as potential mitigative measures needed to offset unavoidable social and economic impacts.

The primary measures identified for the project area include permanent acquisitions, floodproofing by elevation and other means, relocation of public buildings, flood preparedness and evacuation planning, public education, changes in the current municipal and county NFIP and building codes, a transfer of development rights or purchase of development rights program, changes in land use zoning, development impact fees, and redirection of new development. These measures have been combined into 8 separate plans that can be implemented by either agencies of the Federal government or collaboratively by those agencies and state, county and local governmental units. Only local jurisdictions can implement some of the measures identified in the plans through local police powers.

Seven of the 8 nonstructural plans formulated in the following pages are based upon the Advisory Base Flood Elevation (ABFE), in accordance with currently amended local ordinances, to generate comparison of project costs and benefits. The eighth plan (NSC-6) is a combination of structural and nonstructural measures evaluated through the ABFE, 20 feet, 30 feet and 40 feet levels of inundation for ringwalls and ring-levees at certain communities and the LOD 4 structural project. Total nonstructural plan costs range between $6.1 billion for acquisitions of high-hazard properties alone and $19.1B for a full range of nonstructural measures such as permanent acquisitions, floodproofing, relocations of public buildings, NFIP and building code upgrades, and use of TDR or PDR programs.

Due to the iterative nature of the planning process, LOD 4 was screened out after the Nonstructural Appendix was completed. This measure was screened out due to the extreme maintenance cost of the associated surge gates, which was beyond the financial capability of the local sponsor. Therefore, the discussions associated with LOD 4 in the combined structural and nonstructural plans (NSC-6d through NSC-6g) within this Appendix should be viewed only as a reference. The combined structural and nonstructural alternatives that include ring-levees and ringwalls with nonstructural measures and that are labeled as NSC-6 through NSC-6c are still valid alternatives.

Comparison of the 8 plans using metrics such as total plan cost, cost per parcel protected, AAD prevented, effectiveness, sustainability, public safety and environmental quality reveals that several nonstructural plans provide substantial benefits (including substantial non-monetary benefits or

benefits for which monetary measures have yet to be defined in the plan) to the project area. Due to the lack of detailed information for the project study area, several metrics were not commensurable among the plans at this time. Despite this quantification issue, significant qualitative improvements in public safety, environmental quality, potential long-term growth, community disaster-resilience and future damage reduction point to the overall effectiveness of the nonstructural plans.

A planned feature is the High Hazard Area Risk Reduction Plan (HARP) that provides for purchase of properties located in the high hazard zones of the three coastal counties of Mississippi. Acquisition would be in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, as amended, and would be implemented first in the most high risk areas (approximately 2000 parcels)and initially with owners willing to sell.

In addition to the proposed HARP, the plan includes two pilot projects: one for elevation of 25 residential structures in Waveland, MS and another for relocations of essential municipal structures in Moss Point, MS. Each of these two pilot projects would enable testing of key processes and design techniques aimed at reducing flood damages and preventing future loss of life and essential public emergency services during hurricane events. More detailed plans for the pilot projects would be prepared and submitted for approval at Division level prior to implementation.

CHAPTER 1. INTRODUCTION

Although coastal areas of the nation are attractive to commercial, industrial and residential developers, the consequences (as evidenced by Katrina and past hurricanes) associated with locating damageable property and unwary residents along the Gulf coast can be extreme. Despite years of regulation through the Federal Emergency Management Agency (FEMA) and other coastal zone management techniques, damageable property still remains in high-hazard areas and people still drown during surge and flooding from hurricanes.

In short, we must identify strategies and measures that can be used in tandem to both discourage development in high-risk areas and encourage growth in less hazardous areas of the coast. Some strategies and measures may be more appropriate for Federal action while others will be more attuned to local regulatory action and administration. In either case, these measures must be effective, socially acceptable, environmentally suitable and mindful of the existing neighborhood and community social and economic systems within which they would be implemented.

CHAPTER 2. NONSTRUCTURAL FLOOD DAMAGE REDUCTION

2.0 Gulf Coast Development.

According to a NOAA report published in 2003 ("Population Trends Along the Coastal United States – 1980 to 2008"), coastal population within the Gulf Coast region was projected to increase between 10 and 15 percent by 2008. Despite the damaging effects of Katrina, Rita and Wilma in 2005, areas of the gulf coast continue to grow in population and shoreline development. Some areas affected by Katrina in the project area have begun to rebound in large measure due to the reopening and success of the major employers and tourist attractions along the coast. Over 1,600 building permits for new single-family home construction were recorded within the 11 communities in the project area in 2006 (City-data.com).

In addition to the permanent households and commercial businesses that live and work along the Gulf Coast, millions of seasonal tourists visit these same coastal areas giving rise to the boom in vacation rental units, condominiums, second homes, and motels and hotels that populate the Gulf region. Tourist's primal attraction to the Gulf coast also feeds development of a plethora of amusement and recreation related uses that congregate on various boardwalks and beachfront property adding to the potential for high damages. Added to this burgeoning of development along the coast is the presence of millions of transient tourists who may be largely unaware of the threat that hurricanes and storms present to them.

2.1 Nonstructural Measures

Flood damage reduction measures are divided into two distinct components: structural and nonstructural. Structural measures in coastal areas usually concentrate on resisting the surge and wave action of storms and hurricanes. Off-shore and onshore barriers, seawalls, levees, flood gates, pumping systems and other structural measures can provide high levels of protection to coastal development. In-place development (residential, commercial, industrial, and institutional uses) is largely untouched during implementation of structural measures with the exception of acquisitions within the construction footprint of the project features. Much has been written about the positive benefits and negative impacts of structural measures along the nation's coastlines. Generally speaking, structural components have performed successfully during storms and hurricanes, but failures can and do occur when the design parameters of either structural or nonstructural components of a protection system are exceeded by extreme storm events.

Application of nonstructural measures or those measures directly associated with modifying the location, construction or operation of property, structures, and facilities located in hazard areas is one method of reducing storm/hurricane-related damages and saving lives that are at-risk. Nonstructural measures can be applied to both coastal and riverine hydrologic systems and have been proven to be affective in reducing damages and saving lives. Where nonstructural measures have been successfully instituted by local governments through floodplain management or other land regulation processes, the benefits and impacts of the protection process have been largely unreported. This lack of notoriety is due in part to the unit-by-unit or lot-by-lot system of protection (not very newsworthy), the relatively low cost when compared to other protection methods and the lack of massive mobilization of political or financial resources to accomplish these low-tech solutions.

Actions to either modify or remove development from at-risk areas to reduce damages can be applied in two general ways: first is to take direct actions towards the at-risk building or facility so as to modify its structural characteristics or location such that damages are reduced, and second is the application of incentives and disincentives through regulatory or economic processes that cause landowners to re-evaluate the costs and benefits of living in a hazardous location more carefully. Many existing regulatory and land valuation techniques exist that can influence individuals' choice of a building location. All of these techniques need to be considered. Nonstructural measures can be divided into several general categories including:

- Flood Preparedness
    - Hurricane/Storm identification, tracking and early warning
    - Temporary emergency evacuation and sheltering
- Modification of structures, facilities and/or the property on which they are located (a.k.a. floodproofing)
- Building construction regulations (building codes)
- Land use regulation by zoning that affects the type and location of land uses
- Floodplain management regulation, hazards zoning and insurance systems (NFIP/CRS)
- Property taxation, special development assessments and development fees
- Transfer of Development Rights and Purchase of Development Rights (TDR/PDR)
- Permanent evacuation of the hazard areas (permanent acquisition and relocation)
- Relocation of public structures and critical facilities

Each of these general categories of nonstructural measures can be applied as single measures or can be applied in combination with one another or with structural measures to address storm damages and loss of life. The range of benefits, costs and residual damages associated with application of each measure is broad. The extent and severity of social and economic impacts associated with the various measures can be likewise broad and must be identified for any plan. Depending upon the nonstructural measures selected for application and the relative percentage of each applied to the planning area, the future land use pattern of the area could be vastly different than that which existed prior to Katrina's landfall.

Finally, the ability of nonstructural measures to be implemented in very small increments, each increment producing flood damage reduction benefits (structure-by-structure), and the ability to initiate and close a nonstructural program with relatively minimal costs are important characteristic of this form of flood damage reduction. Also important is the ability to "tier" measures over long periods of project time such that a layering of measures, each one providing a higher degree of protection, is possible and given both Federal and non-Federal funding constraints probable. In order to affectively implement multiple layers of nonstructural protection within such a large project area, several tiers applied incrementally may be required before complete protection would be realized. The use of "tiering" will be discussed in more detail during plan formulation.

The following chapters will discuss the various nonstructural measures, program eligibility, nonstructural criteria, nonstructural formulation concepts and the applicability of these various measures in several alternative plans to the MsCIP project area.

CHAPTER 3. PROJECT AREA CHARACTERISTICS

3.1 General Description

Coastal areas of the United States are home to a substantial portion of the total population of our nation. Data published by NOAA in 2003 ("Population Trends Along the Coastal United States – 1980 to 2008") indicated that at least 153 million Americans live within the 673 coastal counties bordering the nation – a land area accounting for only about 17% of the nation's total land surface. This segment of the nation represents 53 percent of the total national population living and working in a continent-sized linear pattern that is subject to frequent and damaging storm events. One of those growing coastal areas has been the Gulf Coast in Mississippi.

The MsCIP project area consists of the Mississippi coast from the western border with Louisiana defined by the Pearl River to the eastern border with Alabama generally defined by Middle Bay. Figure 1 shows the distribution of the 11 municipal areas within the project area and several of the major connecting highways. The area is politically divided into three county governments (Jackson, Harrison and Hancock) and at least 11 municipalities. Three of the eleven municipal areas are grouped into two Metropolitan Statistical Areas (MSA). Prior to the arrival of Katrina in August 2005, the area boasted a population of over 220,000 persons. That population decreased dramatically as a result of Katrina, but is making a come back as local employment increases and the housing market slowly recovers.

Figure 1. Gulf Coast Communities (MRF graphic)

This 75 mile long coast has numerous physical features that make it a prime development location including three main inlets at Bay St Louis, Biloxi and Pascagoula, productive estuaries and wetlands, extensive beaches with flat to moderate topography adjacent to the beach area, and several off-shore barrier islands. The beaches draw millions of tourists each year to this Gulf paradise. The entertainment industry in the form of casinos and tourists attractions has spurred much growth along the beachfront areas. Numerous industries, some directly tied to the Gulf waters, populate the project area and several military and Federal Government-related complexes are dotted across the landscape providing employment and revenues to the local economy.

Several major transportation routes cross through the area including Interstate 10, Route 90 and the CSX railway line each running east-west across the area. The majority of the cultural development is concentrated south of Interstate 10 with agricultural and forested lands mainly north of Interstate 10. Each of the three major embayments associated with tributary rivers has extensive wetland areas associated with them.

3.2 Topography

Among the many characteristics of the project area that directly affect formulation of nonstructural measures, the surface elevation of the landscape with respect to the elevation of the Gulf waters is of paramount importance. Since nonstructural measures generally affect each parcel of property and each structure and facility, the ground elevation at each specific structure location is an important aspect of plan formulation. In the case of the Gulf coast, most structures are constructed on slab foundations therefore the ground surface elevation generally reflects the first floor elevation of the structure as well. For the purposes of data collection and analysis the project area was divided into 54 reaches. Using available GIS information and topographic data layers, the elevation of each tax parcel within the 54 reaches was determined. Table 1 shows the average elevation (NAVD 88) of the identified parcels (geographic center-point of each parcel) within each of the 54 reaches with respect to the Gulf surface elevation. Figure 2 is a graded-color representation of the elevations of the 54 reaches with respect to the Gulf surface. The color differences indicate the relative risks of surge inundation in the reaches. More detailed maps of the project area showing this elevation difference with respect to the Gulf waters are included at the end of this Appendix (See Figures 141 to 145).

Table 1.
Average Land Elevation by Reaches

Reach Number	Elevation	Reach Number	Elevation	Reach Number	Elevation	Reach Number	Elevation	Reach Number	Elevation
1	9.65	12	12.36	23	10.54	34	NP	45	NP
2	11.00	13	16.75	24	10.77	35	7.59	46	15.62
3	13.66	14	17.54	25	12.23	36	10.04	47	15.97
4	5.98	15	16.70	26	10.77	37	17.59	48	15.57
5	5.77	16	13.75	27	11.07	38	15.79	49	15.62
6	8.82	17	NP	28	9.47	39	15.74	50	12.47
7	12.05	18	13.60	29	11.70	40	15.45	51	9.58
8	8.81	19	6.21	30	12.20	41	12.04	52	10.29
9	8.32	20	11.99	31	8.60	42	NP	53	5.17
10	14.54	21	9.94	32	9.18	43	11.73	54	6.81
11	17.54	22	13.45	33	NP	44	NP		

NP – Due to the shape of the reach and parcels none of the identified parcel center-points fell within the reach

3.3 Urban and Community Development

3.3.1 Urban Development Patterns

As mentioned above, the project area is politically divided into11 municipalities contained within three counties. Three of the 11 municipal areas, Pascagoula, Gulfport and Biloxi form two Metropolitan Statistical Areas (MSA's) composed of Pascagoula (37700) and Gulfport/Biloxi (25060).

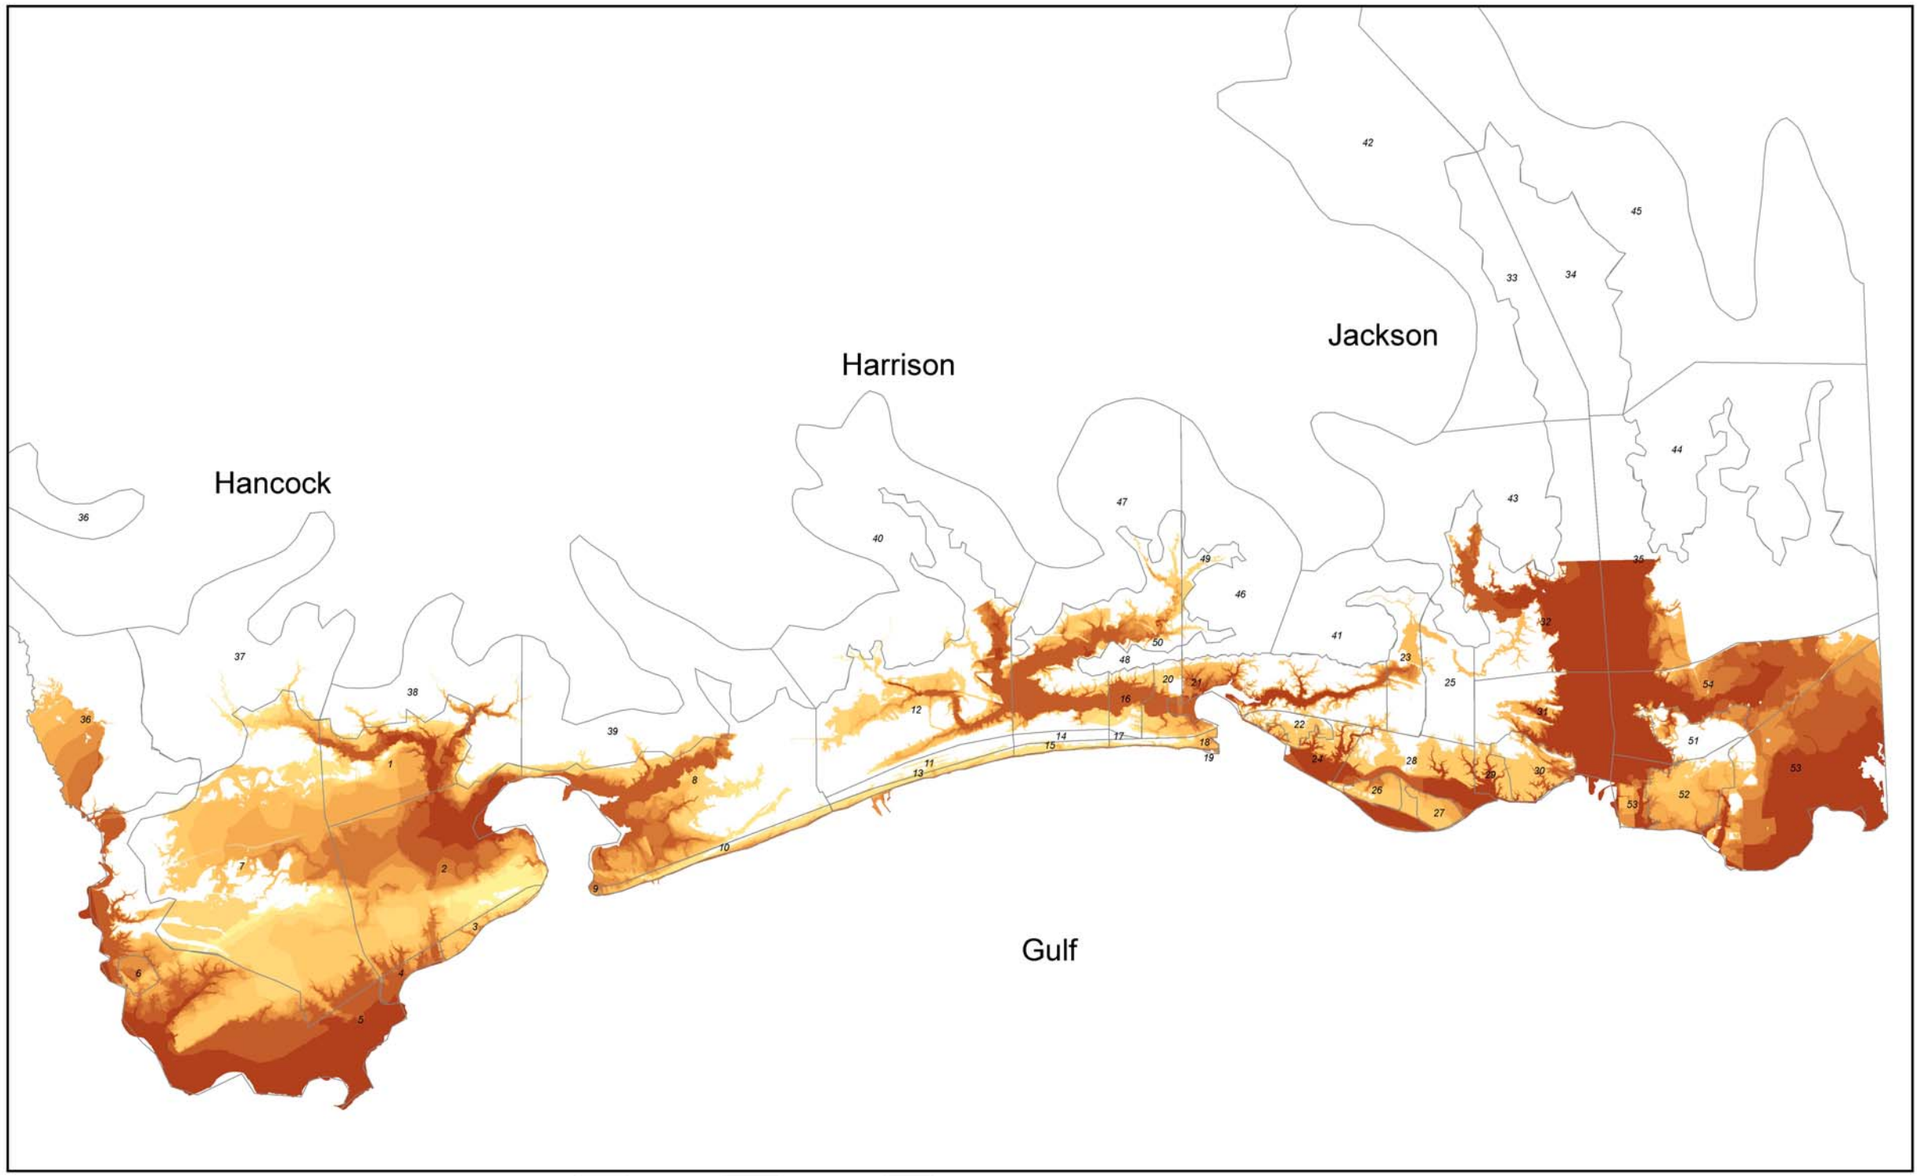

Figure 2. Land Surface Elevations of Economic Reaches w/Respect to the Gulf

MSA's are defined and redefined on a regular basis by OMB, but the basic designation of the MSA is based upon population size. MSA's combine both municipal and surrounding county populations for the purposes of Federal statistics collection. According to the 2000 Census the Pascagoula MSA had a population of 150,564 persons within its economic and social statistical area and the Gulfport/Biloxi MSA had a population of 246,190 persons within that same distinctive boundary.

That statistical designation carries weight when Federal funds are being distributed through social, infrastructure and national security programs. Figure 3 shows the MSA's of Pascagoula and Gulfport/Biloxi (dark green outlined in dark green border) and the 5 county areas included within their statistical boundaries (Picayune within Pearl River County is a separate micro statistical area not included within either the Pascagoula or Gulfport/Biloxi MSA's).

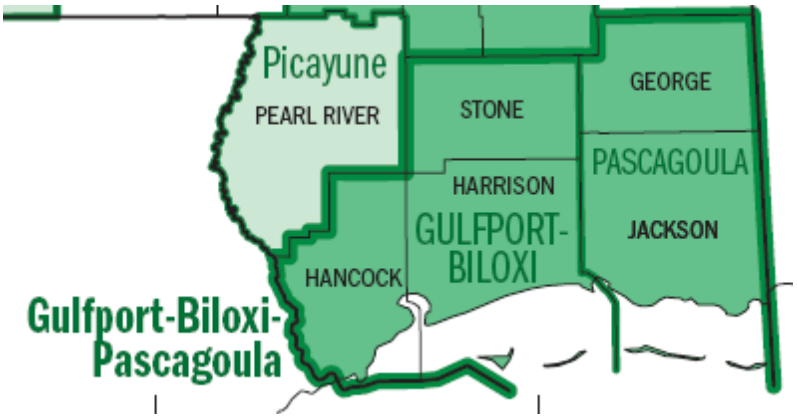

Figure 3. Metropolitan Statistical Areas within the Project Area

These more urbanized communities exhibit relatively large centers of commercial activity and a government core as well as a traditional grid-pattern street layout. All three have older central business districts that have been diminished somewhat by sprawl development that has aligned itself with adjacent transportation corridors (Route 90 and Interstate 10).

The development patterns of the 11 municipal areas are all unique to their location and topography, but most have a defined business/commercial and government center with surrounding various densities of housing and other land uses. Gulfport, Biloxi and Pascagoula have well-defined centers that are conducive to walking and transit services. Primary north-south access corridors from both Gulfport and Biloxi have resulted in a "sprawl" pattern of development emanating from those two centers.

These sprawl corridors have resulted in linear development patterns aligned with the highways. Other communities such as Bay St. Louis, Long Beach, and Ocean Springs have much smaller town centers near the beachfront and conform to a grid-pattern with less apparent sprawl. In some cases, the growing commercial districts of these municipal areas have located away from the beachfront and have aligned with Route 90 and other intersecting highways. Many of the tourist-centered commercial developments (hotels, motels, entertainment areas) migrated to the beachfront highways putting all of them in high-risk locations.

In addition to these older town centers, many of the Interstate 10 intersections bordering the project area have begun to sprout with hotels/motels, service stations, outlet stores and restaurants creating several new centers that attract travelers and offer some competition with the beachfront town centers. Several of the commercial areas near the interchanges have been annexed into the older beachfront municipal areas like Gulfport. Massive residential subdivisions (see below) have sprung up at the interstate intersections creating more flood-safe housing out of the reach of most hurricane

surge events. This recent trend in residential development (north of Interstate10) bodes well for what may have to be a long-term strategy to address future hurricane damages while maintaining the robust economic vitality of the region. Should predictions regarding sea level rise (as described in the future without-project condition scenarios) come to fruition, migration away from the beachfront to higher elevations may be an absolute necessity.

3.3.2 Community Development Patterns

There are several planned development communities (i.e. Diamondhead) in the project area that feature upscale housing and recreation amenities as well as several "golf-course communities" and at least one "fly-in" community within the project area. In contrast to the older grid-pattern urban centers, these newer subdivisions, gated communities and planned unit developments display a more curvilinear pattern with multiple cul-de-sacs and looping streets. These newer community structures are more vehicle-oriented. Additionally, there are several major military or military-related facilities in the project area around which some growth (where allowed) has occurred. These relatively stable employment centers provide a boost to the local economy and an injection of highly-talented people that provide leadership and human resources to local service organizations.

There are several industries and commercial establishments that are more attached to the waterfront than other community land uses. The casino complexes and water-related industries (Ingalls, Chevron, etc.) are required either by law or by function to be at the land-water interface and must remain in that location in order to function. By law the casinos are restricted to an 800 feet wide band along the waterfront, a location which places them in harm's way of hurricane surge, waves and winds. Major industrial employers such as Ingalls Ship Building and the Chevron Company must have facilities at the water's edge in order to either construct vessels or maintain oil platforms. Although these locations are highly hazardous, the continued presence of these major employers in the community is of paramount importance to the social and economic health of the project area.

Both Biloxi and Gulfport have substantial central business districts immediately at beachfront locations. Both of these centers as well as Pascagoula have high densities of commercial, business and residential uses with numerous recognizable neighborhoods. Within the counties there are numerous well-defined neighborhoods (many are named) and a few isolated and unincorporated communities scattered out in the estuaries. The amenities of the Gulf Coast have attracted many hundreds of vacation and second home developments contained in grid-street patterns built upon fills adjacent to the estuaries. Several of these subdivisions have a very low density of housing compared to what would be expected given the grid-street pattern. In contrast to the many upscale vacation housing developments, there are several "fishing-based" communities (i.e. Ansley) nestled into the estuary areas that also are subject to flooding.

3.3.3 Critical Facilities

As with any normal-functioning community, there are a plethora of buildings and facilities that could be classified as "critical facilities" within the project area. Included in this category of facilities are fire stations, police stations, emergency response/management facilities, hospitals, schools, medical clinics, transportation facilities, utilities, and public administrative buildings. All of these facilities, besides being a daily necessity to community life are very critical to the safety and protection of citizens during and after emergencies. Their location with respect to their service areas and inundation limits from storms and hurricanes is of paramount importance in the formulation process.

Both community colleges and state post-secondary educational facilities are located within the project area as well. A large number of churches of many faiths are scattered among the communities and have provided physical and spiritual support to their congregations and others

following Katrina. Much of the rebuilding occurring in the project area is occurring through the work of missions from allied denominations. The usual mixture of social services (welfare, children, clinics, etc.) and public services (utilities, solid waste, communications) account for numerous buildings and facilities throughout the project area – many of which are subject to inundation damages.

3.3.4 Non-Project Communities

In addition to the 11 communities included in the project area, there are numerous villages and unincorporated communities located just north of the I-10 corridor that serve as "bedroom communities" for the thousands of employees that support the tourism industry and commercial businesses along the coast. Few of these communities suffered from inundation damages due to Katrina, but damages to homes and businesses due to wind and rain were significant there as well. Although these communities may not be directly affected by the measures being formulated for the defined project area, they may be affected indirectly by certain measures such as relocations of residents along the coast through a large permanent acquisition program. A more in-depth look at these adjacent communities is included in Section 4.5.9.9.2 and Table 10 of this Appendix.

3.3.5 Historic Districts

A search of the National Park Service database for National Historic Districts identified 18 Historic Districts within the project area (see Table 2). These historic districts are located within the 11 communities discussed above. A Historic District in the United States is defined as a group of buildings, properties or sites that have been designated by one of several entities on different levels as historically or architecturally significant. Buildings, structures, objects and sites within a historic district are normally divided into two categories, contributing and non-contributing. Districts greatly vary in size, some having hundreds of structures while others have just a few significant structures.

Table 2.
Historic Districts on the National Registry

District Name	Community	County
Front Street Historic District	Pascagoula	Jackson
Krebsville Historic District	Pascagoula	Jackson
Orange Avenue Historic District	Pascagoula	Jackson
Indian Springs Historic District	Ocean Springs	Jackson
Lovers lane Historic District	Ocean Springs	Jackson
Marble Springs Historic District	Ocean Springs	Jackson
Old Ocean Springs Historic District	Ocean Springs	Jackson
Shearwater Historic District	Ocean Springs	Jackson
Sullivan-Charnley Historic District	Ocean Springs	Jackson
Biloxi Downtown Historic District	Biloxi	Harrison
Harbor Square Historic District	Gulfport	Harrison
Scenic Drive Historic District	Pass Christian	Harrison
West Beach Historic District	Biloxi	Harrison
West Central Historic District	Biloxi	Harrison
Beach Blvd Historic District	Bay St. Louis	Hancock
Main Street Historic District	Bay St. Louis	Hancock
Sycamore Street Historic District	Bay St. Louis	Hancock
Washington Street Historic District	Bay St. Louis	Hancock

Source: National Park Service Registry data

Some districts cover one or more city blocks while others contain entire neighborhoods or a defined geographic area. The 18 districts identified in Table 2 are listed in the Federal Registry. Other state and local entities may have identified other Historic Districts on the local level that are not included in the NPS database. Those locally significant districts will be identified in coordination with local organizations during more detailed planning of the nonstructural features.

A number of these historic districts are located in the inundation zones most damaged by Katrina and many of the significant structures contained within the districts have been severely damaged by that event. Efforts are currently underway to stabilize (Pilot Stabilization Program) some of the significant historic structures within the project area, some of these structures are included in the designated districts. Should nonstructural measures be formulated that would impact one or more of the Federally-designated historic districts, extensive coordination with the National Park State and the state historic preservation office (SHPO) would be required as part of the NEPA process. Measures that modify buildings or structures within the district to reduce damages (floodproofing) may be considered so long as the architectural or historical character of the structure is not significantly diminished. Options that would relocate large numbers of structures or the entire district to reduce damages would be more problematic.

3.4 Housing Resources

3.4.1 General

Residential units represent a substantial proportion of the total structure categories damaged by hurricane and storm flooding. Because of their relatively light construction (wood frame or masonry over wood frame), residential structures cannot withstand the rigors of hurricane force winds, surge and waves without attention to newer building codes (post-hurricane Andrew). Due to the preponderance of these structure types in the project area and their tendency to be located in high-hazard areas, damages to this category are significant in a major hurricane. More than 60,000 residential units were destroyed by Katrina's fury within the project area (Governor's Commission Report 2005).

As described above, the project area is composed of numerous communities and neighborhoods each having their own personality and character that visually and socially separates them from one another. One of the distinguishing features that separate communities and neighborhoods is the type, quality, quantity, density and age of the housing stock. The project area has a very diverse mixture of older classic-style residences, seasonal vacation cottages, upscale "mini-mansions" and various types of condominiums, townhouses and row-house resources. The more vernacular architectural types are located in the residential neighborhoods of the older urban areas but newer versions of those local architectural styles (i.e. Acadian-Creole) are being constructed in several areas of the project; some even floodproofed by elevation.

3.4.2 Housing Market and Stock Characteristics

Prior to the arrival of Katrina, the housing market in the project area was brisk with many single-family housing construction permits being issued in each of the communities. Table 3 shows the numbers of building permits that had been issued by each community for single-family home construction between 1996 and 2006.

As the table shows, the strong increases in population described in the Socio-Economic Characteristics Appendix during the past decade are reflected in the numbers of housing units being constructed. Of note are the large numbers of single-family residential units for which permits were issued in Ocean Springs, Biloxi and Gulfport during this period. In total, over 10,200 residential

building permits were issued during this 11 year period. Considering that many of these new housing units may have been within the footprint of the regulatory extent of the Base Flood Elevation (National Flood Insurance Program) and constructed so as to reduce flood damages through the local ordinances, the arrival of Katrina (a much greater depth of inundation) probably affected many of these more recent residential structures.

Table 3.
Building Permits Issued for Single-Family Home Construction by Community

Source: City-Data.com NA = Data not available

This consistent rate of residential construction was not abated in 2007. Through June 2007, approximately 1,938 single-family construction permits were issued in the 11 communities and three counties. For communities that appear to be heavily developed already, this level of new residential construction indicates a very healthy and lucrative market for housing construction, mortgage financing and housing contractors in the area. Table 3 does not include building permits issued for multi-family units or condominiums, but field observations of substantial numbers of relatively new multi-family units by the team indicates a strong market in this type of residential construction as well. US Census data indicates that in 2007 (through June) multi-family building permits were issued resulting in construction of over 1,900 new units in the project area.

The 2000 Census data indicates that the average housing stock age across the project area is relatively young. Table 4 shows the relative ages of structures constructed across the project area. Despite the relatively young age of the housing, data indicates that over 6,000 structures still existed in 2000 within the project area that were built between 1900 and 1939. Built long before the use of modern building codes or floodplain management ordinances, these structures remain susceptible to flood and wind damages. Of note is the number of residential structures built during the period between 1970 and the present. Since the communities in the project area (with the exception of D'Iberville) all entered the NFIP in the early 1970's (See Table 7 on Page 44), many homes constructed in this period were subject to the provisions of the initial floodplain management ordinances. Since the year that the initial Flood Insurance Rate Maps (FIRM's) were identified, over 55,000 residential structures have been constructed in the project area.

Table 4.

Source: 2000 US Census (Compiled by City-data.com)

Residential densities range from 1 unit per several acres to 10-20 units per acre in more urban settings. Table 5 shows the densities of housing units (single-family and condominiums) in each of the 11 communities and the relative sizes of the communities in square miles. According to the Governor's Commission on Recovery, Rebuilding and Renewal (2005), more than 134,000 homes were damaged by Katrina and at least 65,000 homes were completely destroyed by the storm. Another 50,000 had flood damages and only 35,000 of those homeowners had flood insurance. The 2000 Census indicates over 152,000 dwelling units were located within the three county areas prior to the arrival of Katrina. Of those dwelling units, 136,000 were listed as full-time occupancy and 4,600 were listed as seasonal or vacation homes. Median housing values ranged from $80,300 to $92,500 prior to Katrina.

Table 5.
Residential Housing Densities (Units per Square Mile)

Community Name	Density per Square Mile	Land Area (square miles)

3.4.3 Housing Styles and Patterns

According to the Pattern Book for Gulf Coast Neighborhoods (2005), a section of the Mississippi Renewal Forum report, there are several distinctive, residential architectural styles found in the project area. Those architectural styles include Acadian-Creole, Victorian, Classical, and Arts and Crafts. Most of these styles were constructed based upon pattern books popular prior to World War II. Within those 4 general architectural categories are building types such as side-hall or “shotguns”, cottages, L-shaped, side gable, pyramid (reflects the roof profile), and townhouses (primarily in dense urban areas). These styles and building types are scattered across the entire project area within the denser urban areas (Biloxi, Pascagoula and Gulfport) as well as the more rural areas of Hancock County. More recent developments across the area reflect modern housing styles such as the one-level “ranch”, split-level, and modifications of several classical styles (Georgian, Tudor, and Greek Revival). Nonstructural measures that directly modify the building construction or add structures in close proximity to the building should be aware of the sensitivity of theses types and styles.

As described above, housing is distributed across the project area in a number of interesting development patterns. Urban housing (townhouses) is associated directly with central business districts like Biloxi and Gulfport and is arranged in distinctive and named neighborhoods emanating from the municipal center. Other concentrations of housing occur along linear streets extending from the beachfront to the CSX railway corridor from Biloxi to Pass Christian in Harrison County and in numerous neighborhoods scattered along the back bays. Much of the older housing in Hancock County is concentrated in Waveland and Bay St. Louis between the CSX railway corridor and the beachfront. Many of these older units were devastated by Katrina. Newer subdivision developments are concentrated along Route 90 with the commercial development. Several outlying, isolated communities such as Ansley and Pearlington are located in western Hancock County and are also subject to flood damages. Housing development patterns in Jackson County range from grid-block urban layouts in Pascagoula and Moss Point to the outlying subdivisions of Belle Fontaine, Gulf Park Estates and the golf course development at St, Andrews.

There are a number of exclusive housing developments scattered throughout the project area. Many of these are associated with golf course developments, airfields, or other recreation facilities (marinas). Housing units within these upscale developments are mostly single-family detached units with some single-family attached condominiums as well. The character of the housing market shifts to a more rural farm style north of Interstate 10 with many large farms and large-lot zoning areas. Some new subdivisions associated with constructed lakes or other amenities are also located north of Interstate 10. Most of these areas were not affected directly by the Katrina surge inundation.

3.4.4 Alternative Living Quarters

Although not directly associated with the housing market, but equally important to formulation of nonstructural measures is the distribution of people living in quarters other than the traditional housing discussed above. Table 6 shows a snapshot of these alternative living arrangements within the project area for communities where census data was available. The 2000 Census lists a number of alternative housing situations for people living in the 11 communities within the project area. Among those alternative housing options are nursing homes, military barracks, correctional facilities, and centers for delinquent or disturbed children and adults, hospital wards for long-term chronic conditions, college dormitories, and non-institutional group quarters.

Table 6.
People Living in Alternative Living Quarters

Alternatives	Nursing Homes	Military Quarters	Correctional Facilities	Mental Health Centers	Hospital Wards	College Dorms	Other Quarters
Communities							
Pascagoula	120	827	257	30	8	0	22
Moss Point	126	NA	16	NA	NA	NA	NA
Gautier	NA	NA	NA	28	NA	NA	24
Ocean Springs	98	NA	4	NA	NA	NA	91
Biloxi	219	2587	NA	20	416	73	108
D'Iberville	NA	NA	NA	NA	NA	NA	NA
Gulfport	243	1137	1059	31	74	93	688
Long Beach	30	NA	NA	NA	161	NA	27
Pass Christian	197	NA	NA	NA	NA	NA	NA
Bay St. Louis	157	NA	133	9	NA	NA	26
Waveland	NA	NA	NA	17	NA	NA	7
Totals	**1190**	**4551**	**1469**	**135**	**659**	**166**	**993**

Source: City-data.com, (US Census 2000). NA = not available

Although the data is incomplete for many areas (many NA's) and types of alternative housing situations (these are not popular community marketing statistics), this data shows that over 9,000 persons, many with disabilities, may be living in specialized centers within the project area at any one time. During a hurricane or storm flood emergency that could affect one or more of these centers, evacuating this segment of the population would be at best problematic. As was evident in the evacuations of hospitals, nursing homes, correctional facilities and other specialized populations during Katrina and Rita in 2005, providing the necessary transportation, security and accommodations for these groups takes pre-planning and good coordination between the evacuated area, transportation providers and the shelters. Having sufficient warning time to evacuate these individuals is critical to reducing loss of life during extreme weather events. Although such evacuations have been successful (with some problems) in the past, other options to permanently relocate these less-fortunate or quartered individuals to less flood-prone areas should be considered in the nonstructural formulation.

3.4.5 Historic Homes and Buildings

A search of the National Register of Historic Buildings database for the 11 communities within the project area identified at least 114 structures, homes, schools, libraries, churches, theaters, hotels, public buildings, taverns, railroad depots, banks, fire stations, commercial and military buildings and sites. Many of these structures were damaged by Katrina and efforts are underway through a MS Pilot Stabilization Program to save the damaged historic structures. Table 37 in this Appendix shows a listing of these historic buildings and sites in the project area. Of those listed, only "Beauvoir" in Biloxi is considered a National Historic Landmark by the NPS. The "site" listings refer to archeological sites for which nonstructural protection measures would not be considered.

In addition to those structures listed in the National Register, there are a number of structures considered by the State of Mississippi and local organizations to be significant to the region's history. Although not considered important enough to be listed nationally (some may be in that process currently), their importance from a state or local perspective warrants consideration in the nonstructural planning process. Coordination with the state and local organizations to determine the locations, flood-risks, and potential protection measures for these important structures will continue during more detailed planning for the nonstructural measures.

Although unconfirmed at this level of planning analysis, it is possible that a significant number of structures listed on either the National Register or on state and local historical lists are located within inundation hazard zones where nonstructural protection options (wet or dry floodproofing) may be limited by wave action and surge depths. The numbers of historic structures being considered in the MS Pilot Stabilization Program indicates that many of these precious resources were damaged by Katrina. Floodproofing historic structures by elevation may be possible but maintaining the historic and architectural significance of a structure while raising the first floor 10 feet would be problematic. For obvious visual reasons dry floodproofing such a structure by constructing a ringwall or veneer wall around the building would be limited to a very low level of protection (4 feet or less). In areas where floodproofing would not be considered (high-hazard wave/surge zones), acquisition and relocation could be used to protect the building in another suitable location, but that option would require extensive coordination with the National Park Service and the SHPO. Replicating the building site so that the historic or architectural character of the building is not significantly diminished would be difficult.

Extensive coordination with the Mississippi SHPO and the National Park Service would be required during more detailed planning and engineering studies for implementation of nonstructural measures that would potentially affect structures or sites listed on the National Register.

3.5 Other Federal Disaster Assistance Programs in Coastal Mississippi

In addition to the nonstructural flood damage reduction program outlined in this Appendix, there are at least two other significant Federal programs currently operating within the communities of the project area. Both the Federal Emergency Management Agency (FEMA) and the US Housing and Urban Development Administration (HUD) have ongoing programs within the project area that are designed to reduce future damages or to compensate landowners for damages as a result of the Katrina event.

3.5.1. FEMA Assistance Programs

FEMA has been operating several post-Katrina programs designed to compensate landowners for storm-related damages, reconstruct and repair damaged structures and reduce future flood damages and loss of life due to hurricane surge and other storm-related threats. FEMA administers the Individual Assistance Program (IAP), Public Assistance Program (PAP), Other than Housing Needs Assistance Program, Debris Removal Program, Temporary Housing Program and the Hazard Mitigation Grant Program within the project area. Each of these programs targets a specific need for either individuals and families or the public sector (public buildings and facilities and infrastructure) and portions of the programs are administered locally by The Mississippi Emergency Management Agency (MEMA). To date over 350,000 individuals and families have been helped by the assistance programs. Most of these grant programs cover losses or needs over and above any flood insurance payments that may be available to the landowner and the grants are provided tax-free.

The individual assistance program provides grant funds to individuals and families for temporary housing, the repair, replacement or reconstruction of homes damaged by Katrina. Those repairs must be made in conformance with NFIP requirements according to the local floodplain management ordinances and the funds do not cover losses to second or vacation homes in the project area. This disaster assistance program is implemented under the Individuals and Households Program (IHP) and provides grant assistance for re-establishment of households in the affected areas. Opportunities for applying flood damage mitigation measures to damage homes are encouraged by FEMA administrators but for those landowners without flood insurance, but receiving

disaster assistance, the mitigation measures are optional. Additional long-term recovery funding can be provided through low-interest loans from the Small Business Administration.

MEMA is also administering the Mississippi Alternative Housing Program that places dislocated families into new “Mississippi Cottage” as alternative housing solutions to travel trailers and mobile homes. The Mississippi cottage is a 308 square foot home that has been designed to withstand hurricane force winds and be constructed for about $35K. Based upon FEMA sources, about 2,400 families and individuals have been moved from temporary trailers into the Mississippi Cottages.

As of April 2008, over 200,000 individuals and families have received Housing Assistance payments and over 130,000 have received Other Needs Assistance grants. Total payments to these two components of the FEMA assistance program have reached $1.2 billion to date. In addition, more than $2.8 billion has been obligated by FEMA in their Public Assistance program helping to reconstruct public buildings and facilities, utilities, roads and bridges and recreation facilities. The Corps’ debris removal funds were included in this total as well with additional funds provided to the US Coast Guard for marine debris removal (data source: http://www.fema.gov/news).

The Hazards Mitigation Grant Program is also being administered in the project area through the Mississippi Emergency Management Agency (MEMA). This program provides grant funds to address flood damages for structures and property that are subject to repetitive flooding or were damaged by Katrina and had been identified for acquisition in the state All-Hazards Mitigation Plan. Projects must show savings greater than costs. A recent $96.5 million hazard mitigation grant to Louisiana was provided to elevate 3,000 structures in accordance with NFIP. Some of the activities that can be implemented under the HMGP to protect either public or private property from future flood damages are:

1) Acquisition of real property for willing sellers and demolition or relocation of buildings to convert the property to open space use

2) Retrofitting structures and facilities to minimize damages from high winds, earthquake, flood, wildfire, or other natural hazards

3) Elevation of flood prone structures

4) Development and initial implementation of vegetative management programs

5) Minor flood control projects that do not duplicate the flood prevention activities of other Federal agencies

6) Localized flood control projects, such as certain ring levees and floodwall systems that are designed specifically to protect critical facilities

7) Post-disaster building code related activities that support building code officials during the reconstruction process

In addition to the HMGP, FEMA offers grants for flood damage reduction through the Pre-Disaster Mitigation Program (PDM) as well. Project components are similar to those described above for the HMGP but can be implemented prior to a disaster event. Again, the PDM is administered through the state and local governments in a designated area and projects must be included in the state all-hazards mitigation plan to be eligible for grant funds.

3.5.2. HUD Assistance Programs

The Homeowner Assistance Grant Program (a.k.a. HAP) is a disaster recovery program being implemented through the Mississippi Development Authority for those areas specifically damaged by Katrina hurricane surge inundation. The program is generally available to low to moderate income households (up to 120% of the median household income) with limited funding for higher-income households. The program is being implemented in two phases – phase 1 for those structures located outside the 100-year flood zone established in the Flood Insurance Rate Maps (FIRM) but were flooded by the Katrina surge and phase 2 for those structures damaged by hurricane surge and located within the 100-year flood zone mapped in the FIRM.

The program has two components. The first component is a compensation grant of up to $150K (phase 1) to compensate homeowners for losses to single-family, owner-occupied duplexes or mobile homes due to flooding by surge that were not covered by insurance. The percentage of the total grant available is dependent upon the insured value of the home times the percentage of damage determined in a damage assessment. Homeowners may repair, replace or reconstruct homes as they choose with the funds. No local permits for home repair or construction or evidence of the use of the funds for those purposes is required by HUD or MDA. Homeowners having flood insurance must comply with NFIP requirements for elevating the structure and may apply for the second component of the program – the elevation grant – to defray the costs of elevating the home. In phase 2 of the HAP, the compensation grant amount is limited to $100K.

The second component of the HAP is the elevation grant and is available to homeowners who did not have flood insurance through the NFIP. The $30K grant helps to defray the cost of elevating the home and is payable in two installments - $15K when the elevation permit is obtained and $15K when an occupancy permit is obtained. This grant is available to homeowners also receiving the $100K compensation grant for residential structure damages under the phase 2 program. Neither HUD nor MDA are providing direct oversight for the elevation design or construction processes, but are relying on local NFIP and building code inspectors to assure compliance with the local ordinances.

Neither the compensation grant program nor the elevation grant program restricts any homeowner from rebuilding a destroyed or substantially damaged structure or elevating a damaged/repaired structure in the new DFIRM-designated V or VE zone. The only requirements are compliance with current NFIP guidelines as described in local floodplain management ordinances and current building codes. Any structure being elevated under either program would be raised to the new BFE established in the DFIRM flood zone mapping. This new BFE elevation may be several feet lower than the surge elevation that came ashore with Katrina. Residual damages during a Katrina-like storm as a result of implementing these elevation and compensation programs could be significant.

As of May 15, 2008, the HAP has received 19,401 applications for Phase 1 and 8,534 for Phase 2 of the program and has distributed grant funds to 20,437 of those applicants totaling more than $1.4 billion.

In addition to the Homeowners Assistance Program discussed above, the MDA is implementing, through the HUD Community Development Block Grant (CDBG) program, the Long Term Workforce Housing Program. The purpose of this program is to provide grants and loans for local jurisdictions, non-profits and for-profit organizations to provide long-term affordable housing in the three coastal counties and Pearl River County. These funds can be used to repair, rehabilitate, or reconstruct housing units for low and moderate income families and must include at least 40 dwelling units for each grant or loan request. The program projects that as many as 5,800 housing units may be created in these four counties.

Among the program requirements are adherence to local building codes and the NFIP for determining first floor elevations of new or rehabilitated structures. Existing structures considered for repair or rehabilitation that suffered damages more than 50% of the structure value by hurricane surge flooding must comply with elevation requirements through the NFIP and local floodplain management ordinances. Applications for Phase 2 of this program are being taken currently.

Sections 4.5.8 and 4.5.9.7 of this appendix address the opportunities for integrating the FEMA and HUD programs with the formulated plans in this report.

CHAPTER 4. IDENTIFICATION AND PRELIMINARY SCREENING OF NONSTRUCTURAL MEASURES

4.1 General

There are a number of measures that can be classified as “nonstructural”. In some cases such as dry floodproofing by the use of ringwalls or ring-levees, a nonstructural measure can approximate a structural solution when expanded to protect a large contiguous complex (college campus, industry, or commercial area). When judiciously applied, nonstructural measures can result in reductions in inundation damages and losses of life to structure occupants. Corps of Engineers documents and regulations as well as the technical papers and bulletins of other Federal and state agencies that address flooding from storms and hurricanes contain lists of possible nonstructural measures. Generally speaking, each of these identified measures can be applied either singly or in combination with other nonstructural or structural measures to attain project goals and planning objectives. Screening of the measures can be accomplished in a preliminary fashion by considering lessons learned from previous nonstructural projects, potential socio-economic impacts, environmental justice issues, and political realities of implementing certain measures at the local government level.

4.2 Damage Categories

Prior to identifying potential nonstructural measures, a quick review of the damage categories to which the measures may be applied is warranted. These categories generally represent the sphere of land uses and property ownership options in the project area. These categories include:

1. Private properties occupied by residences (single-family and multi-family)
2. Private properties occupied by commercial structures and facilities
3. Public properties occupied by public buildings and facilities (Federal, state, municipal and county owned) or other damageable items
4. Private properties occupied by entertainment structures and facilities
5. Private properties that were vacant prior to the Katrina event
6. Private properties that were made vacant by the Katrina event (total structure or facility loss.
7. Public properties that were vacant or made vacant by Katrina.
8. Public properties occupied by industrial development
9. Private properties occupied by industrial development
10. Public utility corridors and installations (substations)
11. Public properties occupied by transportation modes
12. Private property occupied by transportation modes
13. Public parks and open space

Each of these damage categories (listed as either private or public property and attendant structures or facilities) can be addressed by one or more nonstructural measures and several categories of land use include contents damages as well. These land uses and associated structures and facilities are already addressed in county and municipal zoning ordinances, comprehensive plans and floodplain management ordinances. However, there remain a substantial number of at-risk structures and facilities subject to flood damages from hurricanes and storms.

4.3 Loss of Life Issues

Damages to private, corporate and public property along the Mississippi coast were in the billions of dollars, but the most compelling losses were those to human life in the state due to Katrina. Estimates are that more than 250 people perished during the storm in the project area and more than 60 were unaccounted for following the storm and presumed to be missing or dead. The combination of surge, waves and wind overpowered many who either attempted to ride out the hurricane or were trying to escape the storm and waited too long to avoid the surge and waves.

Many who were able to ride out Camille in 1969 believed that they could weather Katrina inside their homes only to discover too late that the surge depths far exceeded previous storms and they perished as their homes were destroyed or as they were fleeing in desperation. Personal interviews from survivors during the planning process revealed numerous people were unable to escape because key evacuation routes were submerged during the storm. Many survivors clung to roofs and trees to escape the surge flooding and waves.

Detailed information on the number of dead within each community or neighborhood, locations of the recovered bodies with respect to their place of residence and the cause of death (drowning, heart attack, impact injuries, etc.) are unavailable at this time due to the sensitivity of that information. Hopefully that information can be disclosed by state agencies during later more detailed planning so that identified high-hazard zones where permanent evacuation may be the most advantageous option and the need for timelier hurricane warnings and safe evacuation routes can be better supported for implementation.

Issues of public safety and loss of life during these extreme weather events have become more significant in the planning process since Katrina. The ability to provide timely storm warnings, safe escape routes and safe shelters is a key component of reducing future loss of life along the coast. In some cases, permanent evacuation of some coastal neighborhoods may be the best way to assure public safety and avoid future losses of life. Alternative plans that integrate various nonstructural measures for the purpose of reducing loss of life will be explored during the plan formulation process.

4.4 Goals and Objectives

The main body of the MsCIP report displays a number of project goals and objectives that address the existing conditions listed in the project study authority. Existing problems to be addressed in the study authority include: 1) hurricane and storm damage reduction, 2) prevention of saltwater intrusion, 3) preservation of fish and wildlife, 4) prevention of erosion, and 5) other related water resource purposes. From these problems, the MsCIP team in coordination with project area stakeholders and cooperating agencies developed goals and objectives that would guide the planning process and could be used to evaluate formulated measures and alternative plans. During the study process, one goal began to emerge that summarized the efforts of the team; formulation of alternative plans that as a result of their implementation, would enable the Mississippi coast to become a disaster-resilient community.

Among the many objectives developed to support that emergent goal (disaster-resilient community) are several that can be directly addressed by nonstructural measures. Those include:

1) Reduction of the potential for future storm created flood damages,

2) Reduction of the potential for future storm related threats to life and safety,

3) Reduce costs for storm related emergency services,

4) Provide environmental justice in recommended solutions,

5) Provide complete solutions (in accordance with the P&G),

6) Provide solutions “acceptable” to communities & resource agencies,

7) Provide environmentally sound solutions,

8) Provide solutions that fit within existing laws, policies, regulations, and the general plans of local governments and communities,

9) Minimize impacts to the environment, and

10) Generate opportunities for ecosystem restoration of wetland habitat.

It is for these stated objectives that potential nonstructural measures and their integrated plans are formulated and against which they will be evaluated for effectiveness, cost effectiveness, completeness, acceptability and environmental suitability.

4.5 Potential Nonstructural Measures

The nonstructural measures described below can be grouped into several general categories including:

- Flood Preparedness and Emergency Evacuation
- Floodplain Management, Floodplain Zoning, Flood Insurance and CRS
- Building Codes
- Land Use Regulation and Zoning
- Development Impact Fees, TDR, TPR, and Redirection
- Land Taxation Policies, Special Assessments and Revenue Sharing
- Floodproofing
- Permanent Acquisitions (Evacuation and Relocation)
- Relocations of Public Buildings (Critical Facilities)

In an effort to simplify the formulation of nonstructural plans and reduce repetition of evermore detailed evaluations of the measures, the following paragraphs include a description of the individual measures, how they might apply to the project area given existing conditions, costs associated with the measure, operations and maintenance costs and whether the measure should be carried forward into the more detailed project formulation process (a preliminary screening of the measures).

4.5.1 Flood Preparedness and Emergency Evacuation

4.5.1.1 General

Flood Preparedness includes a multitude of management activities and features that all contribute to a reduction of flood damages and reduced losses of life due to hurricanes and storms. These management activities can apply to the emergency operations of Federal, state and local agencies as well as to the response actions of individual property owners. During the days and hours that preceded the arrival of the identified and tracked storm known as Katrina, agency emergency operations and landowner responses were already taking place that saved countless lives and reduced property damage. That many more did not perish in the event is a testament to the fact that sound flood preparedness and emergency evacuations were successful.

Generally speaking, storm warnings and emergency evacuations fall under the purview of the National Oceanic and Atmospheric Administration (NOAA) and the Federal Emergency Management Agency that includes offices at state and local levels of planning and deployment. Although the Corps of Engineers is not a direct player in these types of flood damage reduction components, the Corps does support these activities as an important part of reducing flood damages and reducing losses of life. The following measures outline the types of storm/hurricane warnings and emergency evacuation management activities that could be implemented by Federal, state and local managers.

4.5.1.2 Research Findings

Among the many post-disaster studies of hurricane-readiness in the project area, a study conducted by the Harvard School of Public Health (2007) using a random sample of 513 residents by telephone interview revealed interesting attitudes and concerns of the local population regarding flood/hurricane preparedness. Besides the 8 demographic questions included in the survey, each respondent was asked 48 questions regarding their individual or household preparations and specialized needs for evacuation in the event of a future hurricane. Most of the respondents (95 percent) had experienced Katrina and either suffered damages to their residence or were aware of damages in the area.

Many of the respondents indicated a renewed interest in preparedness and had equipped their households with substantial resources and supplies in the event of a future storm. A majority of the respondents indicated as well that they would evacuate the area if told to do so by government officials. If an evacuation were necessary, many indicated that they would leave by personal vehicle and would stay with family or friends up to 200 miles away from the coast. For those who indicated that they would evacuate many concerns were expressed about the safety and capacity of evacuation centers to handle the evacuees. Issues of water and food supplies, safety, sanitary facilities, over-crowding, and medical care were expressed by respondents.

For those who may have chosen to remain in hazardous areas during a hurricane, the primary reasons for staying at their residences included: 1) considered home to be well-built and would be safe staying, 2) concerns about theft and damages to the evacuated home, 3) believed that the roads would be too crowded to safely evacuate, 4) believed that evacuation would be dangerous and 5) needed to take care of someone who would be physically unable to evacuate. All of these issues should be addressed as revisions to certain aspects of the evacuation system to assure that residents who may be in serious peril do not feel compelled to remain during a hurricane and those who choose to evacuate can do so safely and with limited stress.

Studies, such as the one described above, give valuable information regarding the concerns and issues confronting the project area population who would face more hurricanes in the future. Formulating a robust flood preparedness and evacuation system that addresses these concerns is

one of the objectives of the nonstructural PDT. The many components of flood preparedness and potential upgrades of that system are discussed below.

4.5.1.3 Storm/Hurricane Identification, Tracking and Forecasting

Generally, the majority of hurricanes and coastal storms capable of inflicting significant damages to structures in the V-zone develop over days within the Gulf basin. Fortunately, this developmental period allows the National Weather Service and the National Hurricane Center the opportunity to provide ongoing information on the formation of the storms and their probability of making landfall at one or more areas of the Gulf Coast. The opportunity to identify the storm threat, forecast its probable movements and issue advanced warnings for temporary evacuation of high-hazard coastal areas can lead to substantial lessening of loss of life and property damages.

One can only imagine with horror the potential loss of life and property losses that would have occurred had not Katrina been so well tracked and advanced warnings issued for mandatory evacuation of portions of the Gulf coast. Regrettably many who survived Camille in 1969 decided to weather out Katrina rather than evacuate – their names were listed among the dead or missing. This sad fact points out that a flood warning and emergency evacuation program has many facets - any one or combination of which left uncompleted or unheeded can lead to disaster.

The warning and evacuation system is composed of several components: 1) Threat identification and analysis, 2) Forecasting, 3) Dissemination of threat warning, 4) Threat understanding, 5) Evacuation and 6) Sheltering. Today the ability to see the development of hurricanes and major storms within the Gulf is aided by a great number of sophisticated technology and data sources. Weather satellites, Doppler radar imaging, hurricane hunter aircraft, reports from ships at sea, reporting oil rigs, moored buoys, Caribbean weather stations, and many other proven data sources can track an approaching hurricane, tropical storm or major low-pressure system in real time and generate reliable data upon which forecasts of direction, speed, and intensity can be based. Both polar orbiting and geostationary weather satellites provide storm images in visible light and infrared, as well as showing water vapor images of these storms.

Land, ship or aircraft-based Doppler radar provides a detailed picture of rainfall intensity, speed and circulation characteristics within the storm. NEXRAD or “NEXt generation doppler RADar” is much more sophisticated allowing closer examination of rainfall intensity, storm direction and speed as well as measuring wind speeds (motion of dust particles within the storm) in the absence of rainfall. NEXRAD, with a range of more than 140 miles from the radar site, provides much better information on the intensity and speed of hurricanes and other storms in the gulf. There are NEXRAD stations in New Orleans, LA, Biloxi, MS (Kessler AFB), and Mobile, AL. Radar imagining from these three stations overlaps the entire Mississippi coastal area.

In addition to satellite imagery and land and ship based radars, the on-station telemetric data and information generated by the hurricane hunter aircraft provides forecasters a more complete picture of hurricanes and other major storms in the gulf. Flights into major storms begin when storms are still classified as tropical depressions and tropical storms by their pressure and wind speeds. Using Doppler radar and “dropwindsondes” that are dropped from the aircraft during the flight, readings of barometric pressure, wind speed, air and water temperature, storm direction, and speed are delivered at regular interval flights into the storm. These aircraft

The National Weather Service (NWS), a department of the National Oceanic and Atmospheric Administration (NOAA), operates and maintains a series of moored buoys in the Gulf of Mexico that provide a real-time stream of weather and oceanic data. The buoys range in size between 12 meter diameter discus buoys and 3 meter diameter buoys and most are tethered to the ocean floor. Other buoy types include spar buoys with multiple moorings and wandering buoys (NOMAD). Because of their size and sturdier construction, the 12 meter discus buoys are more reliable in hurricane and storm conditions resisting capsizing and wave damage to the structure and instrumentation. Figure 4 shows a 12 meter discus buoy being serviced. Larger buoys such as the 12 meter discus buoy are towed into position by Coast Guard vessels. Spar buoys although more expensive in capital and O&M costs are more stable platforms for satellite telemetry than the discus buoys. Information on air and water temperature, atmospheric pressure, wave heights and wave period, wind direction and speed, and other weather data is up-linked to communication satellites and weather stations along the Gulf.

Figure 4. 12 Meter Discus Buoy (NBDC Photo)

This “hurricane DEW Line” system provides reliable data to the National Weather Service on the speed direction and strength of approaching storms, tropical storms and hurricanes. In addition to the hurricane hunter aircraft that provide atmospheric and ocean condition data from within the storm itself, these buoys relay constant data on weather and ocean conditions at the water surface. The National Buoy Data Center (NBDC) Web Site provides ongoing updates of the buoy data in the Gulf. That web address is: http://www.ndbc.noaa.gov/.

One component of this measure could be buoy system upgrades in the Gulf coordinated with NOAA. Consideration should be given to whether or not additional reporting buoys in the gulf would provide a better picture of the strength, direction and speed of hurricanes, tropical storms and other ocean phenomena that would endanger the coastal area of the state. Having better and more reliable information on the expected height of the storm surge and associated waves would assist emergency personnel in making more informed and quick decisions about which coastal inundation zones are at risk from a particular storm. The inability to correctly select which inundation zones should evacuate quickly erodes the public’s confidence in the warning and evacuation systems.

During Katrina’s relentless approach to the coast, a number of reporting buoys in the middle of the hurricane broke free of their moorings and drifted from their known positions. Although the buoys kept reporting data, without a reliable position, the NWS had no way to locate where those conditions were in relation to the eye of the storm. Consideration should be given to modifying the existing buoys through NOAA programs so that “break-a-ways” during extreme hurricane events due to huge waves or extreme surge depths will not void the valuable data being relayed to the NWS.

Based on information gleaned from NOAA online sources, the installation of the 12 meter discus buoys cost in the range of $2.5M to $3.5M per buoy depending upon water depth and towing

distance. This cost includes buoy construction, installation of instrumentation, towing to the Gulf site and anchoring the buoy. Annual O&M cost for the 12 meter discus buoy is approximately $500,000. Capital and installation costs could be shared between implementing agencies or with a project sponsor and annual O&M cost would be borne by NOAA (cost data supplied from NOAA publications).

Having more precise information on the intensity, location, track and anticipated landfall of severe storms is the basis for any storm warning and emergency evacuation system. Since these measures all contribute to having more precise information on the level of threat that any particular storm or hurricane poises as well as better information to determine where and when the effects of the storm will make landfall, all of these proposed measures should be retained for more detailed formulation.

4.5.1.4 Warning Dissemination

One of the most important factors in being able to successfully and safely evacuate coastal areas is allowing sufficient time between the determinations that a particular storm's track will make landfall at designated locations along the gulf coast and fully disseminating the warning to those in the target area. These predictions are based upon numerous factors of storm speed, direction, intensity, other weather conditions (low pressure and high pressure land systems) in the region. Generally hurricane threat information is distributed to the public as "hurricane watches" and "hurricane warnings" by the NWS. According to NOAA information, a hurricane watch is an announcement by the NWS for specific coastal areas that hurricane conditions are possible within 36 hours. A hurricane warning is a public announcement by the NWS that sustained winds 74 MPH or higher associated with a hurricane are expected at a specified coastal area in 24 hours or less. These watch and warning times are not adjusted according to the strength of the hurricane as the physical radius of the hurricane-force winds from the eye of the storm is usually closely correlated with the strength of the storm (more intense the storm (Safir-Simpson scale) the larger the radius of the storm). In the case of Katrina, the radius of the storm was much larger than previous storms of that intensity (such as Camille).

Information gleaned from various web sites and the three county emergency evacuation plans indicated that at least 36 hours may be required to safely evacuate threatened zones along the coast prior to the larger storm events (categories 4 and 5). Although there is much concern over issuing evacuation orders too soon without sufficient information to accurately determine where landfall will occur, the potential for many people to be trapped on crowded roads when the storm surge arrives or to wait till that last possible moment before evacuating gives some credence to the possibility of issuing a warning in advance of 24 hours when hurricanes reach Categories 4 and 5. A considerable number of people lost their lives while fleeing from Katrina. In addition to the existing dangers of evacuating high-risk project areas, should a nonstructural plan featuring thousands of elevated structures be implemented, having sufficient time available for those households to evacuate safely will be a major component of that plan.

Due to the number of large recreation facilities and operating industrial plants that cannot be moved from high hazard areas, specific warning systems should be developed that notify these people-filled facilities on an ongoing basis about potential threatening storms and expected hazards at their specific locations. Specific evacuation procedures for each of those facilities would be prepared in close coordination with the facility management and local emergency management personnel.

One of the many warning measures that should be investigated further with NOAA and the NWS is the possibility of extending the hurricane warning time from 24 to at least 36 hours in the advance of landfall for the larger more powerful storms with hurricane force winds and surge that extend across larger areas. Especially for any hurricanes in the 3, 4 and 5 categories that affect larger areas of the

coast. Based upon all accounts of Katrina's approach to the coast, its size and the extent of damages and loss of life wrought by the surge, a longer warning time may have saved lives.

Other forms of emergency notification of the population living along the coast in hazardous areas are available. Reverse 911 systems that generate phone calls to homes and businesses in selected sections of the coast that are correlated to the current emergency evacuation plans would be an effective way of issuing storm warnings or evacuation orders. In addition, these same systems could use cell phone technology (voice mail, text messaging, paging, etc.) to contact individuals with that service. In either case such notification systems could be effective in issuing evacuation orders and if repeated on a regular hourly basis in advance of storm landfall may decrease the chances for loss of life. Given the diversity of the population within the project area, hurricane/storm warnings should be issued in several languages as well as sign language on public television stations. Other warning dissemination methods should be explored that would address physically and mentally disadvantaged populations in the region as well.

Despite all of the various forms of media available to the population within the project area (i.e. television, radio, internet, cell phones, broadband, etc.), there is no guarantee that individuals will have access to the media, that the media systems will be functional at these critical times, or that individuals would be aware of impending threats from storms or hurricanes at all times. For this reason, other less sophisticated systems should be in place that would provide unmistakable evidence that there is an impending threat approaching the coast.

As a nonstructural measure, a system of sirens located across the project area could provide an emergency signal whose message would be unmistakable given sufficient education of the population of the purpose and meaning of the sirens' use. Mounted on wind-resistant poles located at intersections and serviced with underground power, the sirens could be used in conjunction with other media and communications systems to alert the population to the coming threats. For the hearing impaired, flashing strobe lights could also be installed in neighborhoods so that all segments of the population could be notified of impending danger.

Warning sirens installed on a pole mount range in costs from $15,000 to $25,000 depending upon the anticipated coverage area and required pole height. Battery backup systems are available for that price range. Costs include the siren, pole and wiring plus installation costs. Annual O&M costs are approximately $500 per siren. Flashing strobe lights range in costs from $250 to $500 installed depending upon the wattage and mounting location. Annual O&M costs for the flashing lights would be contingent upon instances of vandalism and theft and would be limited to purchase of a new strobe light and its installation.

Generally the majority of the population within the project area has access to various media (television and radio) that would be carrying information from the National Weather Service on local news stations regarding the threat levels of oncoming storms and hurricanes. However, there are sectors of the population who do not have ready access to media resources and therefore may not be made aware of these impending threats. In light of this situation, a nonstructural measure could be to distribute weather service radios that continually provide weather related information on an impending hurricane or storm event. Considering the growing diversity of the population in the project area, announcements of impending weather-related emergencies need to be broadcast in multiple languages.

The National Weather Radio (NWR) system is a nationwide network of over 900 radio stations broadcasting continuous weather information directly from a nearby National Weather Service office. NWR broadcasts National Weather Service warnings, watches, forecasts and other hazard information 24 hours a day. There are three NWR stations in the project area including Mobile, AL, Gulfport, MS and New Orleans, LA that provide full coverage of the project area through the weather radio system. The special radio receivers or scanners that pick up the NWR information can be

purchased from the NWS or many other commercial outlets. For the hearing or sight impaired population, these alert systems can be connected to other alarm systems (flashing lights, sirens, etc.) in the home or business. Standard NWR receivers cost approximately $80 and could be purchased in bulk for distribution to identified sectors of the project area population that would be at risk and lacking the resources to purchase the radios. A significant number of those needing these resources could be addressed with a modest project investment at the current unit price. Annual O&M costs would be limited to battery replacements unless rechargeable batteries are chosen (slight increase in purchase cost).

The ability of emergency services agencies to quickly and decisively issue credible warning is a key element in an effective storm/hurricane warning system. Since all of these measures contribute to that system's effectiveness, all of them are carried forward into more detailed formulation.

4.5.1.5 Evacuation Planning & Public Education

Once the threat of an approaching storm has been determined by the NWS, specific steps can be taken by local communities and emergency services personnel to begin evacuating those families and individuals and their movable contents to safe areas. Emergency evacuation zones of the coastal region have been mapped based upon surge depths, wave action and FEMA flood frequency data. Those families and individuals as well as concentrations of special populations (hospitals, assisted living, schools, jails, etc.) in structures subject to inundation are notified by county or city emergency services to evacuate to safe areas designated by the counties. Specific evacuation routes have been identified by the three counties that will assist evacuees in finding the safest and quickest way to flee the approaching storms.

Each of the three counties has developed emergency evacuation plans that indicate when the various zones must be evacuated, the best available evacuation routes (streets, roadways and highways) and where safe temporary evacuation centers are located. Theses plans need to be better coordinated with Federal and state agencies and departments and better disseminated to the public at large. Telephone, short-wave and cell phone communications enable emergency personnel to coordinate these activities with local police and fire units in the cities.

One of the most important features of any emergency evacuation plan is the education of both the emergency personnel responsible who will be implementing the plan and the citizens who must respond to the emergency evacuation orders posted by local authorities. Many people perished during Katrina because of their lack of information or understanding of the deadly threat that the storm surge and waves would pose for anyone staying within the expected surge inundation zones.

Regardless of the amount or quality of pre-emergency planning and preparation accomplished prior to the next weather-related emergency, the one constant random element remains the reactions/responses of the at-risk population when mandatory or voluntary evacuation orders are issued. Reducing the potential loss of life and injuries to the evacuees depends largely upon the population's understanding of the threat and what appropriate responses to that threat will be effective for each household or individual. Knowing where evacuation routes and safe evacuation centers are located can make the difference between safety and tragedy.

In order to better equip the at-risk population, a series of training and information seminars, media presentations, and other public forums assisted with easy-to-read and understand materials could be implemented as a nonstructural measure. Information on these emergency subjects can be placed in libraries, community centers, hotels and motels, managed-care facilities, hospitals, banks, credit unions and post offices. Applicable web addresses, phone numbers, radio station frequencies, and emergency evacuation routes could be stressed in this public information. The costs of these

materials would be minimal since they are already available through Federal and state agencies. Training and information seminars could be hosted by FEMA, MEMA or USACE at minimal costs.

In addition to educating and training the general population, the most effective education for the project area's future would be at the elementary, middle school and high school education levels. Education materials including textbooks, coloring books, workbooks, posters, computer programs and role-playing games could be distributed throughout the school systems to increase the awareness and understanding of all school-aged children (in a non-threatening way) about hurricanes, flooding and emergency responses to these conditions. Generally parents of children made aware of threats at school seem to respond in a more affective and positive way out of concern for their children's safety. Additional resources available through FEMA for children can be found at: http://www.fema.gov/kids.

Obviously this education process cannot be a one-time affair as new citizens move into the coastal area over time and emergency personnel change jobs, retire or move elsewhere for employment opportunities. More importantly is the fact that the project area is visited by millions of tourists each year – people who may be unaware of the potential threat from these storms and who may not have adequate transportation (such as fly-ins) to evacuate safely. Education of the public must occur on a regular basis about the threats that hurricanes and other large storms present and what steps the public can take to protect themselves and their property. Certainly this public awareness needs to be heightened with the approach of each new hurricane season. At a minimum, annual emergency drills and testing of the warning system are the measures that assure quick and affective response to these threats. Education at all levels (elementary through elderly) is important to assure public safety.

An additional concern would be for the many facilities that are inextricably tied to the water's edge either by legal restrictions (casinos and associated facilities) or by their need to operate at the water's edge (Ingalls Shipbuilders, Chevron Oil, MS Power Company, Port of Gulfport, etc.). Special evacuation plans for these major industrial and recreation facilities will need to be developed in close cooperation with the local emergency management offices and the individual facilities themselves. Costs for development of these individual plans would be shared between USACE and a non-Federal sponsor.

The effectiveness of any threat identification and warning system is inextricably tied to the timely and correct response by the general public, agencies and organizations who will be most effected by the threat. An unheeded warning or a warning not taken seriously is a formula for disaster. Since effective and ongoing education of the public to the seriousness and reliability of the warnings that may be issued in the future is the key to a successful evacuation, all of the above measures regarding public education and evacuation planning are being carried forward into more detailed formulation.

4.5.1.6 Evacuation Routes and Signage

4.5.1.6.1 Evacuation Routes

The population of the communities within the project area is increasing daily as households and commercial businesses re-establish in the area. When a hurricane warning is issued by the NWS for certain reaches of the Gulf Coast and particular areas known to be at-risk from surge inundation and waves are notified to evacuate, there would be a massive migration of people in vehicles from the coast. The massive vehicular evacuation experienced in areas of Texas during the approach of Hurricane Rita in 2005 illustrates the importance of having designated routes.

During an emergency evacuation situation, identified evacuation routes are critical to assuring that those families and individuals that are at risk in identified evacuation zones can safely and efficiently leave the danger zone(s) and seek shelter in designated areas. In addition, the evacuation routes provide efficient routes for evacuation of people by buses or other transit vehicles that may not have access to personal vehicles. Generally the routes are streets, arterial roadways and highways designated by the county emergency services agencies in cooperation with the State Department of Highways which in this case is the Mississippi Department of Transportation.

Figure 5 shows the MDOT Hurricane Evacuation Routes (in red) that extend northward from the coast. In selecting the appropriate routes, the distribution of the population within the hazard zones, highway capacity (lanes and roadway width), critical intersections, bottleneck areas (reduced lane-widths) and other parameters are all critical factors. Planned improvements to those critical components of the evacuation routes can dramatically improve the efficiency and safety of the evacuation process.

Of most importance is ongoing education of the public as to the location of the routes and the locations of designated shelters. This process can be woven into the everyday activities of the state DMV regional offices from the testing of new drivers (drivers test manuals) to the annual vehicle registration renewal, (information included in the registration package) and license renewal processes. Public service announcements (television and radio and published media) identifying the evacuation routes by highway number, name and/or by graphics could begin prior to the start of hurricane season (June) and continue on a regular basis through November.

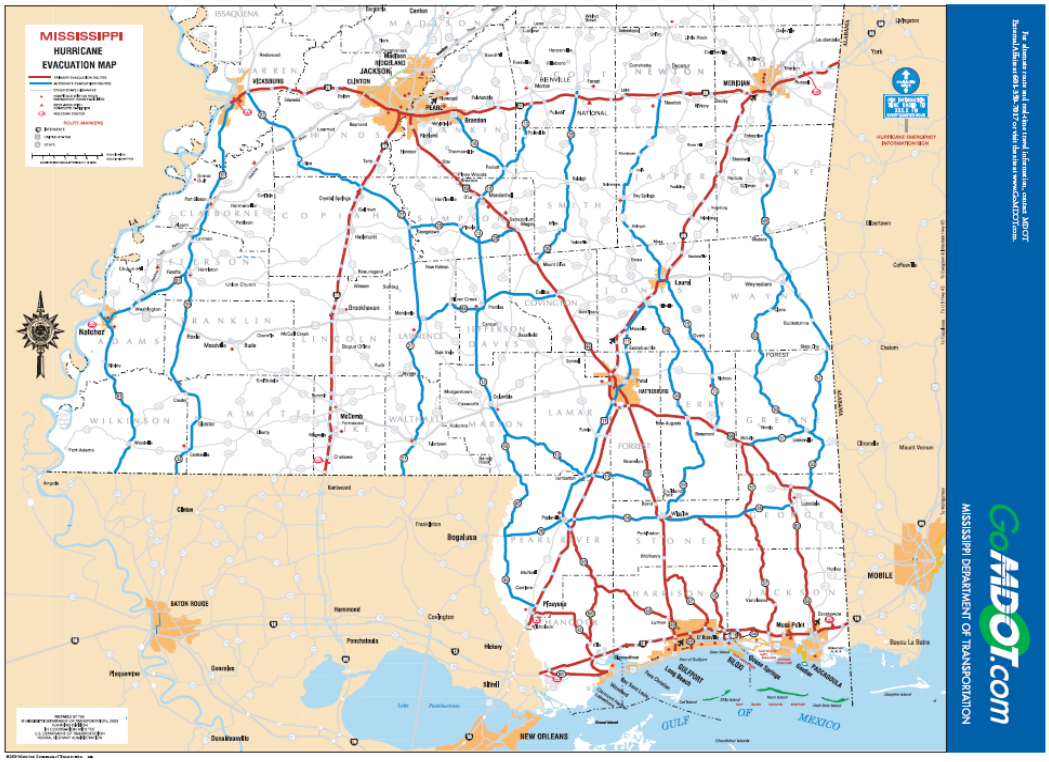

Figure 5. Evacuation Routes MDOT

4.5.1.6.2 Evacuation Route Signage

As important as selecting safe and efficient evacuation routes is the signage of the selected routes such that citizens can quickly identify the appropriate routes and be assured that they are still on an approved route as they travel away from the hazard zone. In addition to full-time residents fleeing an approaching hurricane, a great number of tourists and out-of-region visitors are living in temporary residences (rentals, motels, time-shares, etc.) in hazardous zones as well. Since hurricane season begins in June, the areas beaches and oceanfront properties may be crowded with families and individuals who are ignorant of the threat and the evacuation plans. Their unfamiliarity with the local highways and roadways can make evacuation for everyone a nightmare. Having carefully conceived and wisely installed highway signage that clearly identifies evacuation routes is of paramount importance to successful evacuation. Figure 6 shows a basic hurricane evacuation route sign using the cyclonic logo that is commonly used to designate hurricanes throughout the nation. Placement of theses signs at appropriate intersections and frequently along the evacuation routes could be initiated through a Federally-funded program (Homeland Security) using MDOT as the local sponsor and installer of the signs.

Figure 6. Hurricane Evacuation Route Sign

Costs for the signs range from $250 to $350 installed depending upon the number produced and the installation methods used. Annual O&M costs for the signage are limited to replacement of a percentage of signs due to vandalism or theft.

In addition to the standard metal post signs, other types of signage can be installed that would provide fleeing motorists with information on traffic accidents, available shelters and other important information. Dynamic information signs that flash messages to approaching motorists can be installed along major evacuation routes at strategic locations. Installation options range from smaller pole-mounted roadside signs to multi-lane towers that span 3-4 lanes of traffic. Costs for these installations range from $100,000 (roadside) to $400,000 (multi-lane tower) and annual O&M costs range from $4,000 to $7,000 for the messaging board itself. These signs could be located along the main evacuation routes from the coast to convey up-to-date emergency information to motorists.

4.5.1.6.3 Highway Routing

Reverse-flow traffic routing (also known as “contraflow”) of highways during emergency evacuations is an effective method of moving large numbers of vehicles away from the coast in a relatively short period of time. Successful implementation of this measure requires the full cooperation of the MDOT and adjacent states, and local and state police in planning and administering the reverse-flow routing of traffic during these emergencies. Pre-planning of the target routes away from the coast, modification of intersection signaling, additional turning and travel lanes, dynamic messaging boards and highway signs are all components of this measure. As in the case of other flood preparedness measures, public education is a valuable component of this measure and would require repetitive application to maintain preparedness.

Costs for additional traffic lanes, turning lanes or intersection improvements (see below) are not available without more detailed planning and coordination with MDOT. Annual O&M costs would be commensurate with annual O&M costs experienced by MDOT for lane maintenance.

4.5.1.6.4 Intersections and Modal Crossings

During a major hurricane storm event that would initiate substantial numbers of evacuations from the coast, three primary modes of transportation along the coast would be energized to move damageable assets further inland. In addition to the obvious highway routes already identified above that would attract personal cars, trucks, buses, military vehicles and other vehicles exiting the coast, CSX railway and gulf vessels would also be attempting to move valuable assets away from the coast. Where these various transportation routes intersect (at-grade crossings, bridges, overpasses, etc.) evacuation conflicts can occur. Although major highway intersections can be signaled to reduce conflicts between local and emergency evacuation traffic, at-grade railway crossings occupied by railway stock being relocated in advance of a hurricane event can effectively block thousands of fleeing motorists.

Likewise, fishing fleets and pleasure craft seeking shelter in safe anchorages within tributary rivers and embayments that result in raised drawbridges can also block thousands of fleeing families. These inter-modal conflicts can be resolved along major evacuation routes through an intentional program of expenditure by state and private companies. In addition to these inter-modal crossing conflicts, most of the evacuation routes cross multiple streams and rivers that can be reaching flood-stage as pre-landfall precipitation swells these intersecting drainage-ways. A MDOT-led assessment of all culvert sizing at small stream crossings and maintenance of debris removal in stream/creek channels would help to assure that the major evacuation routes are indeed available during an emergency.

Determining costs for eliminating at-grade crossings, drawbridges and other intersection conflicts require more detailed planning and engineering investigations than are possible given the time and resources available for this appendix. Intensive coordination with MDOT could determine capital and O&M costs for these measures.

4.5.1.6.5 Evacuation Route Resources

As Hurricane Rita so vividly pointed out to the residents of Louisiana and Texas and the rest of America through CNN news, there are a myriad of possible accidents and crises that can take place during a full-scale Gulf coast evacuation. Accidents, vehicle fires, breakdowns, medical emergencies, insufficient fuel supplies and many other on-roadway emergencies can occur during the movement of thousands of households and residents. Contingency plans that address possible needs along each designated evacuation route from the Gulf need to be prepared based upon lessons learned from Hurricane Rita and the needed resources (fuel, emergency responders, repair facilities, etc.) either put in place by state emergency offices or county emergency services or provided for through joint agreements with local resource providers. Annual emergency evacuation tests should include mock activation of these in-route resources to assure their availability in the event of a real emergency.

As in the case of other evacuation activities, determining capital and O&M costs for developing these resources along the evacuation route are not possible at this level of planning detail.

The largely successful evacuation of the Texas and Louisiana coasts preceding the landfall of Hurricane Rita in 2005 is a testament to the need for good evacuation route planning, signage and other measures discussed above. Many of the unexpected incidents that occurred during that evacuation and were highlighted on national media can be avoided and measures for that purpose are included above. Since these measures can contribute to a more orderly and safe evacuation from coastal areas, they are all carried forward into the more detailed formulation process that follows.

4.5.1.7 Evacuation Centers/Shelters

In addition to those evacuation centers that may already be listed by the local emergency management agencies, a series of alternative centers should be identified for use by the coastal population. In consideration for the numbers of people that attempted to evacuate the MS coast immediately prior to landfall by Katrina and later Rita in Texas, having an oversupply of evacuation centers available is important. Should there be a number of schools and other large facilities relocated as a part of the implementation of this comprehensive plan, then these additional "safe" resources need to be added to the list of evacuation centers. Location by GPS coordinates and mapped in GIS format would help all emergency managers and resources (police, National Guard, etc.) manage the evacuations. Additional information on the design and construction of community shelters can be found in the publication: FEMA 361 – Design and Construction Guidance for Community Shelters.

Emergency evacuation of families during Katrina and Rita identified needs for accommodations for specific populations requiring special medical care (elderly, children, chronic illness, and hostels) as well as family pets. Provision for these "special" evacuees should be considered at the identified evacuation centers.

Once identified, emergency-use agreements between local emergency managers and facility owners need to be executed for use of evacuation centers so that administrative processes or finances do not hinder the evacuation process when an emergency is declared. Annual review of those agreements as a part of the annual emergency system test would assure updating of the agreements and any financial considerations.

In addition to the identification of usable evacuation centers and execution of use agreements, provision of basic necessities for a relocated population for up to a week need to be considered. Caches of storable food, water, medical and bedding supplies need to be established at or near the evacuation centers. As with other components of the emergency evacuation system, these resources should be evaluated on an annual basis when the system is tested.

Determining costs for rental of potential evacuation centers and their supply with basic necessities requires a more detailed study of the center capacity needs and coordination with owners of available centers.

Generally speaking, sufficient, safe accommodations of sufficient capacity to handle thousands of evacuees in the face of an impending hurricane landfall are not readily available within the project area. The many hotels and motels within the project area are usually booked during a significant portion of the hurricane season and many of those are currently subject to surge flooding or wind damages. Moving north from the coast, sheltering options (hotels and motels) are limited to small communities located along the identified evacuation routes. Other sheltering options are limited to larger schools and community facilities located away from the coast. Being able to locate these optional facilities, pre-arrange for their use in the event of emergencies and assure that sufficient supplies are on hand in the event of a hurricane landfall are all key components of a safe and efficient evacuation. Since all of these measures contribute to those objectives, they are carried forward into more detailed formulation.

4.5.1.8 Safe Harborages/Anchorages

Of the many commercial enterprises that exist along the Mississippi coast, the commercial fishing and seafood industry is one of the most enduring, most profitable and most threatened by hurricanes and storms in the Gulf. Besides the significant affects that these storms can have on the aquatic life and their habitat that these industries depend upon (fish, oysters, scallops, shrimp, etc.), protecting the fleets of corporate and individually-owned fishing boats and trawlers during these damaging

storms is a challenge. During Katrina, many of these large vessels were swept into the coastal forests and residential neighborhoods and the waterside infrastructure destroyed by the storm surge and waves. With the approach of large hurricanes that carry significant surge heights, damaging waves and high winds, this fleet is faced with certain annihilation if it stays within unprotected waterfront anchorages. The options are to either move laterally across the coast to eastern or western Gulf ports outside of the storms' fury or move further inland using available tributary channels. In many cases, upstream anchorages away from the coast are blocked by bridges and shallow channels and sailing either east or west along the coast to avoid the storms significantly wears on machinery and crews and increases operating costs.

A solution to this temporary relocation problem may be the establishment of safe harbors or anchorages that fleet, charter, and pleasure craft can seek temporary shelter within. In addition to the commercial fishing and private vessels, charter fishing boats, and rescue/emergency response craft could be berthed at these harbors to allow quick response rescue operations following a hurricane event. A number of these "safe-harbors" could be established within the existing embayments by special authorities or through existing Corps of Engineers' authorities such as Section 107 of the Continuing Authorities Program (CAP).

This standing authority provides an opportunity for the Corps to participate in the development of small boat harbors and navigation improvements. The current maximum limit of Federal participation in this program is $7.0 million per project (WRDA 2007). Local sponsors pay a share of the project cost based upon the depth of the harbor. At a minimum, three safe harborages could be located within the project area. In accordance with the regulations governing this program, the estimated project cost for each of the three safe harborages would not exceed $7.7 million. More detailed analysis of the safe harborages' cost and features would be developed in CAP feasibility study documentation.

Safe harbors could be designed as excavated slips or longitudinal channel-side berths with tie-ups designed to accommodate significant rises in water levels (surge inundation). Landside development would be minimal with security fencing, lighting and roadway access. Prime safe harbor sites would be located adjacent to channels or deep water within the embayments that avoid excavation within sensitive estuary habitat. Extensive coordination with natural and marine resources during site selection and excavation design and construction would minimize ecosystem impacts.

A safe harbor could be developed in conjunction with the Pearlington community redevelopment scenario as part of the required borrow material excavation along the Pearl River. Requirements for channel depth and needed dredging would need to be coordinated with the fishing industry as well as natural resources agencies. Coordination with MDOT plans for any future bridge replacements or elimination of drawbridges for evacuation purposes may benefit the safe harbor selection process. See Figure 7 for an example of a safe harborage or safe anchorage. The provision of safe harborages as a method of reducing damages to commercial and pleasure vessels was suggested in the "Potential Projects List" (item HRR1-06) developed during round one of the public workshops on the Comprehensive Plan.

Costs for safe harborages or anchorages would depend upon the expected number of evacuating vessels and their sizes, draft depths being accommodated, intervening channel deepening requirements and needed security facilities. Determination of the capital and O&M costs for these facilities would require extensive coordination with fleet owners and boating associations in the project area. Annual O&M requirements would be limited to dredging the harbor area and any modified channels between the Gulf and the harborage site.

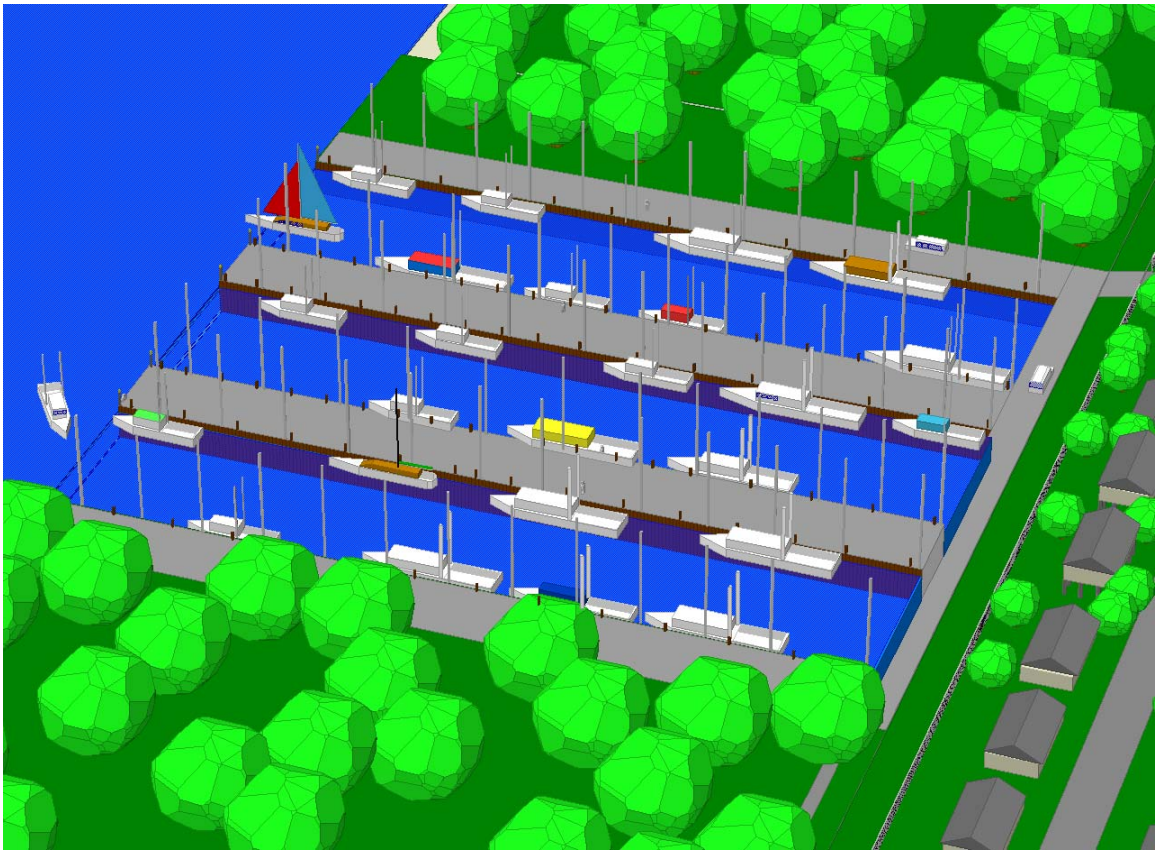

Figure 7. Safe Harborage/Safe Anchorage

The seafood and boating industries are major contributors to the region's economy and are a key component of the tourist trade along the coast. Severe losses such as occurred to the fishing fleets and recreation watercraft during Katrina pointed out the necessity of having sheltering areas for this equipment and facilities. Since safe harborages and anchorages would provide such shelter for this equipment, these measures are all carried forward into more detailed formulation.

4.5.2 Floodplain Management, Floodplain Zoning, Flood Insurance and CRS

Riverine and coastal floodplain management through the auspices of the Federal Emergency Management Agency (FEMA) is one nonstructural measure that has proven to be very effective in reducing damages to structures and losses of life. Generally floodplain management does little to reduce damages to structures grandfathered in their present at-risk location at the time of enactment of the required ordinance, but the awareness that the delineation of the flood hazard zone has upon at-risk residents may lead to retrofits of the structure under existing programs (FEMA HMGP) or other measures that can reduce damages or loss of life.

Floodplain zoning which can be viewed as a distinct overlay zone applied to a standard land use zoning map was established and is regulated by the National Flood Insurance Program (NFIP) under FEMA, an agency within the United States Department of Homeland Security. Under the floodplain zoning program, municipal and county governments can establish flood hazard zones along watercourses or ocean/gulf shorelines according to an analyses of the flood hazard by FEMA. The Flood Insurance Rate Map (FIRM) established for a municipal or county area indicates various levels of flooding, the regulatory floodway or coastal V-zone and elevations of the various flood events. The

availability and cost of Federally-subsidized flood insurance to the landowner are based upon this hydraulic data.

4.5.2.1 Existing NFIP Ordinances, Zoning and Insurance

Each of the three counties within the study area and all of the municipal areas are participating in the regular program of the NFIP. Table 7 shows the progressive entrance of these governmental units into the NFIP. In 1969, Hurricane Camille ravaged the Mississippi coast resulting in over 130 deaths,

Table 7.
City and County Participation in the NFIP

Community or County Name	Initial FHBM Identified	Initial FIRM Identified	Current Effective Map	Regular or Emergency Date

Source: FEMA NFIP data

over 3,800 dwelling units destroyed and damages exceeding $900.0 million. In the preceding year, Congress had enacted the National Flood Insurance Act of 1968. Although in its infancy, the National Flood Insurance Program was beginning to assist counties and communities across the nation that suffered repeatedly from riverine and coastal flooding when Camille hit the coast. Following the catastrophic affects of Camille, the three coastal counties (Hancock, Harrison and Jackson) and all 11 municipal areas affected entered the regular or emergency program of the National Flood Insurance Program by 1978. According to FEMA data, approximately 20,200 flood insurance policies were in affect in the project area prior to the arrival of Katrina.

In the early stages of the NFIP, information on appropriate methods of protecting coastal structures (V Zone) was limited, but engineering standards for raising structures on piling or piers were available and had been proven in many cases to withstand the savage pounding of surge, waves and wind from hurricanes along the Mississippi coast. Hundreds of structures were elevated along the coast to a theoretical 100 yr storm level established by FEMA. As Table 7 shows, most of the 11 municipalities and 3 counties in the study area had initial Flood Insurance Rate Maps (FIRM) in place by 1978. In the intervening 26 years between Camille and Katrina, the study area has been visited by several hurricanes and tropical storms (Cindy 05, Elena 85, Georges 98 and Hanna 05) that tested the flood damage reduction measures instituted through the NFIP.

Fortunately, none of these storms was severe enough to cause extensive damages to coastal structures. Not until the arrival of Katrina in 2005 was the Mississippi coast confronted with another powerful hurricane that would test the flood damage reduction efforts of the local population. Post-

event assessments and visual images of the damages to both seemingly protected and unprotected structures indicated that not all types of protection schemes were successful in the face of a combination of significant surge depths, wave heights and high winds.

Katrina's storm track traveled squarely over the mouth of the Pearl River at the Louisiana/Mississippi border and across the unincorporated community of Pearlington in Hancock County. This track put the coastal communities of Waveland, Bay St, Louis, Pass Christian, Long Beach, Gulfport, Biloxi, Ocean Springs, Gautier, and Pascagoula at the mercy of the northeastern quadrant of the hurricane where sustained hurricane-force winds, a massive storm surge and powerful waves demolished most unprotected structures. Unfortunately, hundreds of structures raised on various types of piers and pilings were likewise demolished as the huge surge (mimicking Camille in 1969) carried battering waves to the first floors and exterior bearing walls of wood-frame structures. Hundreds of these structures raised in compliance with local coastal management ordinances and constructed according to adopted building codes were unable to withstand this onslaught. Figures 10 through 17 on Pages 67 and 68 show the remnants of structures raised to the 100yr flood elevation (BFE). Observations of the Katrina damages showed that all concrete block and brick masonry columns founded on slab foundations failed. Most failures occurred at the junction of the column and the slab. In some cases, reinforcing bars were bent or ties failed at the junction between the column structure and the slab foundation (see Figures 38 and 39 on Page 79). Generally all wooden pilings and post foundations survived the Katrina surge and waves although in almost all cases the structure was washed off the top of the raised foundation by surge and waves.

As a result of the extreme damages and losses of life caused by Katrina, FEMA immediately began to re-evaluate the current BFE and other established flood levels upon which the existing coastal floodplain management ordinances along the Gulf Coast had been founded. Based upon this re-evaluation, FEMA issued a set of "Advisory Base Flood Elevation" (ABFE) maps for the Mississippi and Louisiana coasts. The new ABFE significantly raised the previous BFE elevation along the coast and inlets to acknowledge the potential damages that could be generated by a second storm that mimicked the surge, waves and wind generated by Katrina and to provide guidance for those who would be immediately rebuilding structures and facilities along the coastal areas.

Several project area communities adopted the ABFE's as the basis for their existing floodplain management ordinances and new construction has been held for the most part to those modified base flood elevations. In some cases, the communities just increased the amount of freeboard between the existing BFE elevation and the first floor of a raised structure to compensate for the differences in the new ABFE elevations. A few communities chose to use both techniques according to the flood threats within their area. Table 8 lists those municipalities and counties in the project area that either adopted the ABFE or modified the freeboard requirements for new construction or structure elevation in their existing ordinances. In addition to adoption of the new ABFE, participation in the flood insurance by area residents increased by 165 percent to around 53,600 policies.

Table 8.
Municipalities and Counties Modifying Existing Ordinances to ABFE

Community/County Name	Adopted ABFE	Modified Freeboard Requirements

Source: FEMA Document dated March 2007

FEMA is generating a new set of Digital Flood Insurance Rate Maps (DFIRM's) that will be published for public review and comment by the affected counties and municipal areas. The revised maps will show modified boundaries and heights for the BFE (1% annual chance event) and 500 year (0.2% annual chance event) including revised water surface elevations associated with these zones. It is possible that the revised mapping may include adjustments to the V and VE zone boundaries as well. Once comments are received from the affected county and municipal areas, FEMA will publish the new FIRM's and the local governments will modify their existing floodplain management ordinances to incorporate the new zones and any additional text changes in the ordinances.

In view of these coming changes in the existing floodplain ordinances and recent FEMA design guideline initiatives, there are two potential early-action measures that could be instituted by local jurisdictions to reduce damages to future development along the coast. Each municipality and county should adopt the new DFIRM mapping and ordinance information when published by FEMA. In addition each municipality and county should adopt the *FEMA 550 Recommended Residential Construction for the Gulf Coast* guidelines that describe building methods and flood-resistant materials to be used in elevating or otherwise floodproofing structures in the coastal and inlet inundation zones. These guidelines could be adopted as a part of the undated building codes (see Section 4.5.3 below) or by reference in the floodplain management ordinances. Use of the FEMA 550 guidelines for future coastal construction could substantially reduce damages from future storms. Costs for both of these measures are minimal and are local administrative and legal costs.

4.5.2.2 Community Rating System (CRS)

The Community Rating System (CRS) is a voluntary program for communities that participate in the regular program of the NFIP. The primary objectives of the CRS are to reduce flood losses, facilitate accurate insurance ratings, and promote the public's awareness of flood insurance. The rating system provides a list of incentive activities that would take a community beyond the basic requirements of the NFIP to provide a higher level of protection to at-risk structures. Application of the incentive activities by the community results in discounts on flood insurance premiums for all insurance holders. The rating system ranges from 10 (lowest ranking and a 0% discount on premiums) to 1 (highest ranking a 45% discount on premiums). The incentive activities are grouped into four categories including Public Information, Mapping and Regulation, Flood Damage Reduction and Flood Preparedness. As a community implements incentive activities from one or more of these categories in their community, all participating landowners receive greater insurance premium discounts. Table 9 below shows the communities and counties within the project area that are included in the CRS program and their current ratings. Of the three counties and 11 municipal areas in the project area, one county and 8 municipal areas are participating in the program.

Table 9.
Municipalities and Counties Participating in the CRS

Community Number	Community Name	CRS Entry Date	Current Effective Date	Current Class	% Discount for SFHA	% Discount for Non-SFHA	Status
285251	Bay St. Louis	10/1/95	1/01/00	7	15	5	C
285252	Biloxi	10/1/96	10/1/03	7	15	5	C
280332	Gautier	10/1/94	04/1/00	8	10	5	C
285253	Gulfport	10/1/96	10/1/01	8	10	5	C
285255	Harrison County	10/1/03	10/1/03	8	10	5	C
285257	Long Beach	10/1/00	10/1/00	8	10	5	C
285259	Ocean Springs	10/1/92	10/1/02	8	10	5	C

285262	Waveland	10/1/93	10/1/06	5	25	10	C

Source: FEMA documentation

An effective nonstructural measure would be to encourage the remaining counties (Jackson and Hancock) and the 3 municipal areas (Pascagoula, Moss Point and D'Iberville) to participate in the CRS and realize the discounts in insurance premiums for their participating landowners. Implementation of several of the identified nonstructural measures would significantly increase the participating communities and counties current ratings and further reduce their insurance premiums. Costs for entering the CRS and complying with the requirements are minimal and local.

4.5.2.3 Potential Modifications to the National Flood Insurance Program in Coastal Mississippi

The NFIP is a complex Federal program of floodplain zoning regulations, construction and retrofitting guidelines and flood insurance requirements that is largely administered by local jurisdictions. In general the availability of government subsidized insurance for structures located in the nation's floodplains is contingent upon a county's or municipality's willingness to establish a local floodplain management program based upon the identified flood risks and to accept establishment and enforcement of floodplain zoning ordinances. Over the years since the program first began (1970), there have been numerous modifications of the NFIP based upon changes in insurance coverage, percentage of government subsidy, experiences in enforcement of the program nation-wide and major flood damage events such as Katrina. In view of these changes, other modifications to the NFIP could be possible in the project area that would, over time, result in changes to the development pattern and therefore reduce the potential for flood damages in the project area. These modifications would be affected through Congressional legislative and Federal agency administrative actions. Some of the possible modifications to the program that can be considered as nonstructural measures are discussed below:

4.5.2.3.1 Suspension of the Flood Insurance Program

Many structures along the nation's coast are only located in a hazardous location because of the opportunity to have the costs of flood damages offset by claim reimbursements from FEMA through the NFIP. Although FEMA has established limitations on the amounts of insurance coverage (more about that feature below) and significant structure damages require certain building modifications to reduce future damages, many structures only remain on a hazardous site because of the presence of insurance. In many cases, without that insurance coverage, landowners would eventually abandon their high-risk sites for more flood-safe locations. Usually, federally subsidized home mortgages and business loans require flood insurance on the structure when it is located within a defined hazard zone. In view of this, removing the flood insurance program either in part or totally for

the entire coastal area in MS would have a direct impact on individual landowner's decisions to locate or remain in these hazardous areas. The insurance program for all zones could be dropped or just in the high-hazard zones (VE and BFE zones) or the zones could be dropped in a multi-year phase-out program starting with the VE zone.

Although somewhat "Draconian" in nature, this measure would place the full burden for repairs and recovery solely on the landowner whose home or business was damaged and on public institutions in the case of damaged public buildings. Certainly, removing the flood insurance coverage for homes and businesses in these areas would impact the lending institutions which have based their financial investment in the at-risk structure on the existence of flood insurance coverage that offsets the financial losses to the property and maintains the value in case of future ownership transfers. Depending upon the reaction of the lending institutions to the loss of flood insurance, the movement away from the coast could be rather sudden as at-risk mortgages were voided or remaining mortgage balances were required of the owners.

Should the reaction of the lending institutions not be quite so sudden, in time, gradually and based upon the number and severity of future storm events, landowners who were faced with a severely damaged home or even with frequent minor damages to their home would look for other flood-safe locations. Without a specific timeline for removal of these structures from the flood risk area, there is not an accurate method of determining when the flood damage benefits of this measure may occur. Since the gradual movement away from the coastal area would be event determined and since most large hurricane events are very infrequent, flood damage reduction benefits generated through this insurance driven migration from the coast could take decades to realize.

Although from a theoretical standpoint, abandoning the NFIP for this project area would in time result in a movement away from the hazard areas and a realization of flood damage reduction benefits, the administrative and political actions required to affect such a change in the NFIP would be loathsome to local officials and political interests. The billions of dollars of investment in coastal development within the project area supported by this insurance system would be left at the mercy of Gulf storms and the financial losses could be disastrous to the local economy. Therefore, suspension of the NFIP for the project area will not be carried into the formulation process as a realistic measure.

4.5.2.3.2 Reduced or Suspended Federal Subsidy

Another NFIP-based measure would be to significantly reduce or drop the federal subsidy on flood insurance policies for structures grandfathered into the NFIP when it was enacted within each community or county. Reductions in the Federal subsidy for flood insurance have occurred in the past. Without the federal subsidy or a substantially reduced subsidy, landowners would be faced with paying the full or nearly full actuarial rate for the insurance based upon the risk level for their home or business. This increased "land rent" cost would influence many to move away from the high-hazard areas. For wealthier landowners whose structure is located in a relatively low-risk zone (i.e. 500 yr zone), this reduction or loss of the subsidy would be a moderate impact on their disposal income, but for those less fortunate with a home or business in a higher risk zone (VE or BFE zones), this loss of subsidy may result in "forced" relocation to a less expensive piece of land.

This difference in measure impact calls up issues of equity and environmental justice in its application (may disproportionately affect low-income, fixed-income and minority populations) and may not be justified for that reason. Therefore reducing or suspending the Federal subsidy as a flood damage reduction measure is not being carried forward into the formulation process as a realistic measure.

4.5.2.3.3 Skewed Premium Rate Structure

Current flood insurance rates are based upon actuarial rates founded on the risk of damages from a series of flood events. When the insurance rate is established, landowners are required to pay a set-rate monthly or annual payment to cover the risk. Unless there is some change in the insurance program or flood risk, the monthly or annual payment remains consistent throughout the term of the insurance policy. Under this flat-rate policy it is possible that an insurance provider could suffer a significant loss on a damaged property early in its coverage period that would not be covered by paid insurance premiums.

To provide more protection for the insurance provider and challenge the landowner's decision to build a structure in a high-risk zone, the insurance payment schedule could be modified to require much higher up-front payments based upon the risk. For example, if a normal policy would require an annual payment of $2,500 ($208 per month) over a term of 10 years ($25,000 total), the revised policy (as a nonstructural measure) might require $10,000 in the first year, $7000 in the second year and the balance ($8,000) over the last 8 years. Under this method, the insurance provider would recover a larger amount of the total payment sooner to cover possible early-term losses and landowners would be faced with a financial disincentive to develop in a high-risk zone. The skewed rate structure could be based upon the increased level of risk with development in the VE zone or BFE zones having greater payments up front and structures in lower risk zones (500 year) having less premiums up front.

Again like the option of increasing the landowner costs for flood insurance by reducing the subsidy, skewing the payment schedule to collect a larger percentage of the total premium up-front may have a disproportionate impact on the low-income, fixed income and minority sectors of the coastal population and brings up issues if equity in its application. Wealthier landowners could absorb the larger initial payments while low income owners would be unable to afford such payments. Adjustments to the skewed rate schedule could be made to account for disproportionate impacts on low-income and minority populations, but surge inundation and wave impacts do not take into account one's bank statement. For these reasons, measures that would adjust the flood insurance premiums payment rate will not be carried forward into the formulation process.

4.5.2.3.4 Mandatory Flood Insurance

Although not an effective method of reducing flood damages or reducing losses of life, flood insurance is an effective way of reducing the financial impacts of flood damages to landowners and public entities. Many structures exist within the project area that do not have flood insurance and were damaged by Katrina. Not only does that uninsured condition place landowners in a difficult financial position regarding repair and re-occupancy of the structure but impacts the community by loss of property value (reduces property tax revenues over time) and potentially loss of business taxes.

In most cases, new home construction and occupancy is financed by a mortgage from one of a number of various financial institutions (banks, credit union, etc.). Under Federal law, new homeowners of structures determined to be within a flood hazard zone are required to secure flood insurance to protect the investment of the financing institution. Failure by the financial institution to assure the purchase of flood insurance for the new structure exposes that company to severe financial penalties. For this reason most new home and business construction found to be in a flood hazard zone is covered by flood insurance. However, in certain circumstances where a mortgage is not required to construct the building, this flood insurance step may be circumvented by the landowner.

In addition to the financial necessity of acquiring flood insurance, all county and municipal areas that participate in the NFIP will require a floodplain permit for any structure placed or constructed in an identified flood hazard zone. That permitting requirement will normally trigger the requirement for purchasing flood insurance by the building owner. However, in some areas of the coast, the oversight and enforcement of the existing floodplain management program is not at a level that assures full insurance coverage and many structures are placed or constructed without a permit and without insurance.

In some areas either dated flood hazard mapping or the lack of sufficient mapping results in new structures being placed or constructed in heretofore unidentified flood hazard zones. These structures, located in ignorance of the hazard, remain unprotected by insurance or appropriate building methods commonly used in flood hazard zones. This problem could be reduced by updating the flood insurance rate mapping in previously unmapped areas, but funds for that FEMA-supported process are limited.

In order to assure that all new and existing construction is adequately protected from the financial losses associated with storm and hurricane inundation and waves, all structures located within defined flood risk zones could be required to purchase and maintain flood insurance on the building and its contents. This mandatory feature would need to be instituted by the state, the counties or municipal jurisdictions for the project area as a more restrictive requirement over and above what is required by FEMA on a national scale. Such action by the local jurisdictions would provide financial benefits to the at-risk property owners as an upgrade to the local floodplain management ordinances through the CRS (see above). This mandatory requirement (no exceptions and regardless of the structure financing arrangements) for flood insurance in all zones with associated severe penalties (financial or administrative) for non-compliance would at least reduce the financial losses associated with large storms and hurricanes.

Mandating flood insurance for all structures located within an identified flood zone would reduce financial losses to landowners and other charitable organizations that frequently shoulder the financial losses due to flooding. However, merely having flood insurance coverage does not in and of itself reduce flood damages or the chances of loss of life. Many insured structures and their occupants were lost during Katrina. Since the objectives of the project are to reduce flood damages, not just to recover the financial losses due to flooding, mandating flood insurance coverage on all structures is not carried into the detailed formulation process.

4.5.2.3.5 Reduction in Maximum Insurance Coverage for Eligible Structures

Currently, the maximum flood insurance coverage per structure through the NFIP is $250,000 for residential structures (plus an additional $100,000 in personal property (contents) damages) and $500,000 for commercial business structures (plus an additional $500,000 for commercial building contents). Special options are available for condominium structures whereby blocks of unit coverage at $250,000 each can be purchased with the additional $100,000 contents damages coverage for each unit as well.

These upper limits on insurance coverage promote construction of large and expensive residential structures as well as condominium units and relatively large retail and office structures in high hazard zones. A modest condominium development of 50 units located in a high hazard flooding zone could place upwards of $12.5 million dollars worth of potential structure damages and $5.0 million dollars worth of personal property damages in jeopardy of loss. The recorded insurance losses from Katrina and similar storms along the Gulf Coast are a testimony to these liberal limits placed on individual structures and contents.

An affective nonstructural measure could be a significant reduction in the insurance coverage allowed for all structure types and personal property (building contents). Were insurance coverage limits to be reduced to a more moderate level ($80,000 per residential structure with $32,000 contents coverage - same ratio of contents to structure coverage as provided presently), there would be far less expensive residential structures and condominiums located in high hazard flooding zones. Similar reductions in insurance coverage for commercial structures (for example…$100,000 per structure with $50,000 contents coverage) would significantly reduce high value commercial/business development in high hazard zones. Although flood damages would still be possible, the financial losses to the flood insurance program would be lessened significantly in time and the lower limits may steer some types of development away from the waterfront entirely.

An alternative to reducing the overall coverage limits for all hazard zones would be reducing the insurance coverage commensurate with the level of flooding threat. For example, reductions in insurance coverage could be greatest in the VE zone with lesser reductions in the BFE and 500 yr zones. This method would better recognize the varying levels of risk associated with flooding along the coast and allow substantial growth to occur in the less risky areas.

Reductions in insurance coverage could be phased in over a 5 year period allowing landowners the opportunity to adjust their structures, contents, and locations to account for the percentage of structure and content value that would actually be covered by insurance in hazard areas. Concurrent changes in mortgaging terms by financial institutions to account for the reductions in insurance coverage would further encourage development to abandon the high hazard flood zones.

Reducing the insurable limits on floodplain development so that high value development is not encouraged in high-hazard areas and thus subject to loss would be a good method for reducing the financial losses due to storms and hurricanes. Reducing the limits of insurance coverage on residential and commercial structures would not directly result in a reduction in actual flood damages due to these storms but only compensation of the landowners for their losses. This measure also does not directly result in reduced risk of loss of life and in some ways may contribute to those losses in the future. Since the project objectives emphasize reductions in actual flood damages and loss of life rather than compensation for losses, reducing the insurable limits of flood insurance as a nonstructural measure is not carried forward into the formulation process.

4.5.3.2.6 Cumulative Damages or Cumulative Improvements as a NFIP Compliance Trigger

Currently under the NFIP regulations, any structure suffering storm/hurricane damages whose dollar value is greater than 50 percent of the assessed value of the structure triggers the requirement that the structure come into compliance with the NFIP regulations and the local floodplain management ordinance. That requirement could include elevation of the first habitable floor of the structure to the base flood elevation (BFE) identified in the current FIRM. Generally that damage calculation is completed and measured on an event-by-event basis and is not cumulative over several events.

Information from MEMA indicates that the State of Mississippi requires that counties and municipalities in the NFIP gather information on the value of structure improvements in the project area. When the dollar value of those improvements exceeds 50 percent of the assessed structure value, the structure is required to meet the requirements of the NFIP and local floodplain management ordinances. In addition to this state requirement, based upon information also from MEMA, the City of Pascagoula requires under their local floodplain management ordinance that storm-related damages used to trigger compliance with the NFIP and local floodplain ordinances be accounted for cumulatively over a ten-year period. Should the dollar value of the damages accumulated over that ten-year period exceed 50 percent of the assessed dollar value of the structure, that structure must be brought into compliance with the NFIP and local ordinances regarding the elevation of the structure's first floor with respect to the BFE.

Given the potential for a series of storm/hurricane events to result in significant but not substantial damages (as defined by FEMA to be greater than 50 percent of the assessed value of the structure) to a structure, thus indicating a structure in a location where repetitive damages may be possible, using the accumulation of damages over a period of time (say ten years or the lifetime of the structure) may result in more structures being brought into compliance or more structure owners deciding to move out of areas that receive more frequent flooding.

In light of these existing requirements, a modification of the local ordinances of each of the three effected counties and 10 effected municipalities (Pascagoula already using the cumulative damages process) would be to adopt the process of cumulative damages (over a period of time chosen by the local community or county) as a trigger for requiring compliance with the NFIP and local floodplain management ordinance. According to MEMA, the state requires collecting cumulative costs of improvements for each structure, local jurisdiction information that is made available by owners through the building permit process. The fee amount for the building permit is based upon the value of the improvements and there are financial penalties for undervaluing the cost of improvements. Using the dollar value of cumulative damages as a NFIP compliance trigger in combination with improvement values would help to assure that more structures come into compliance with the NFIP and that future damages are reduced.

4.5.2.4 Training and Education of Floodplain Ordinance and Code Administrators and Officers

Each of the three counties and 11 municipalities in the project area is participating in the regular National Flood Insurance Program. Under the regular insurance program, each of these governmental units has an adopted floodplain management ordinance and floodplain zoning maps of their jurisdiction. Once adopted by the general population of the city or county, the ordinance and all of its requirements (floodplain development permits, zoning variances, mapping, etc.) must be enforced and administered by a designated individual (Floodplain Administrator, Building Administrator, Zoning Officer, etc.) or office of that jurisdiction. In some cases communities contract out these services to specialized firms in zoning and ordinance administration, but generally this work is accomplished by the hired staff of the jurisdiction (i.e. planning and zoning department, public works, community development, etc.). In some cases, staff assigned to these positions are newly hired or do not have all of the up-to-date training available from FEMA and other sources.

Interpretation and administration of the zoning ordinances and use of the flood insurance rate maps requires specific skills and training to be proficient in their application and to avoid unnecessary legal actions. In addition to the basic tenants of the floodplain management program, changes in the NFIP occur on a regular basis requiring someone at the local level to be responsible for making necessary changes in the local ordinances and mapping to maintain compliance with the newest FEMA requirements.

FEMA provides ongoing training for local floodplain management officials as well as real estate brokers, insurance agents and those seeking certification in floodplain management and administration. Training classes are offered at selected sites throughout the USA as well as in FEMA regional offices. Some training is offered on the Internet or through home study by FEMA supplied materials.

A nonstructural measure that could be implemented at a relatively low cost would be jointly sponsored USACE/FEMA training classes for local floodplain management staff, mayors, county supervisors, city councils, Chamber of Commerce, hotel/motel associations, real estate brokers, surveyors, architects, engineers, and financial institutions. This training could be held on an annual basis or as new regulation or mapping changes emerged that affected the project area.

Costs for this measure would be confined to USACE and FEMA employee labor and travel costs to attend and administer the training classes. Annual O&M costs would be repeat training costs for new floodplain managers entering the system.

Considering the relatively low cost of providing this training and the potential benefits to the coastal residents that a better educated cadre of floodplain managers and zoning administrators would generate, these measures are all carried forward into more detailed formulation.

4.5.3 Building Codes

Like land use zoning, the adoption and enforcement of building codes is a police power of local governments enabled by state legislation. Building codes normally are limited to structure design and construction methods and materials selection to meet building use requirements and both environmental and weather conditions at the building site. Structure foundations, structural integrity, site grading to promote positive drainage, and utilities are all part of a comprehensive building code. Provisions for addressing flood-prone locations in the design and construction of structure foundations are an important feature of a well-prepared code and make its use in coastal areas imperative.

Application of building code requirements to the design and construction of structures has been proven to significantly reduce damages due to inundation, wave action and winds. Generally, building codes are enacted and enforced through municipal and county ordinances. In some cases code application and enforcement occurs through city and county planning offices, community development departments or public works departments. Local adoption of building codes is encouraged by insurance companies, fire marshals, building contractors, mortgage financing institutions and real estate brokers. In flood hazard areas including V-zones, FEMA encourages all communities to enact and enforce these codes as a preventative measure in reducing insurance losses under the NFIP.

Over the years of code enactment and enforcement, a number of different code standards have been promoted. At the turn of the century, the insurance industry developed what many consider to be modern building codes in response to major urban fires in the United States. The National Board of Fire Underwriters published its National Building Code in 1905 as a model code; that is, a standard code that could be adopted by any locality. Localities could add additional construction restrictions but the basic model was the minimum standard for building construction.

During the first half of the twentieth century, three major regional model code organizations evolved. Building Officials and Code Administrators International, Inc. (BOCA) founded in 1915, International Conference of Building Officials (ICBO) founded in 1926, and Southern Building Code Congress International, Inc. (SBCCI) founded in 1940. The International Code Council (ICC) was established in 1994 as a nonprofit organization dedicated to developing a single set of comprehensive and coordinated national model construction codes. That ensuing “International Building Code” is now generally accepted as the national standard for building construction and its requirements for building construction in flood hazard zones (including V-Zones) is widely acclaimed as a major step in construction technology.

As a nonstructural measure that would be effective in reducing future flood damages, each of the 11 municipalities and three counties should adopt the latest version (2006) of the International Building Code (IBC) and Residential Building Code (RBC) as their standard building codes and especially enforce those sections (or Appendices) of the codes that pertain to construction of residential and commercial buildings in flood hazard areas. Adoption and enforcement of the IBC would assure to a certain extent (with qualified inspections during construction) that structures built or additions to

buildings in flood hazard zones are able to withstand the forces of water, waves and wind generated by storms and hurricanes and that water-resistant materials are being used in the construction.

Based upon a search of the city and county government Internet sites within the project area, several of the municipalities and counties have already adopted the 2003 version of the International Building Code as their standard building code. The code administration offices of each county and municipality should be encouraged to adopt the updated 2006 IBC (residential and commercial versions) which includes special considerations for flood-resistant construction. Based upon the ICC publication "Code Changes Resource Collection – 2006 IBC" dated June 2006, there have been numerous code changes between the 2003 and 2006 versions of the IBC. Many of these changes are specifically aimed at reducing damages to structures that would be located in flood hazard zones. Additional changes have been incorporated into the 2006 version of the IBC and RBC that address wind damages as well.

In addition to the adoption of the updated IBC in the project area, special education classes should be established in local Vocational/Technical Centers, universities and colleges that offer training in the use of the updated IBC to code administrators, contractors, architects, building inspectors, and landowners contemplating significant repairs to their structures that would require a building permit.

As a nonstructural measure, the recent publication of the FEMA guidelines for construction in Gulf Coast flood hazard areas should be adopted by the counties and municipalities as a part of their floodplain management zoning code and/or their building codes., The FEMA 550 *Recommended Residential Construction for the Gulf Coast* provides valuable design and construction guidelines for various types of residential buildings including building and site evaluations, construction processes, foundation designs, flood resistant materials, engineering data and information sources. In 5 chapters and several appendices this publication provides sound technical information for elevating structures in flood hazard zones.

The FEMA 550 guidelines give technical information on elevating residential structures in the V zones although the recommendations in this nonstructural plan are to strictly to avoid that practice because of the dangers posed by storm surge, waves and hurricane-force winds that would be prevalent in the V zone. In view of the potential for storms and hurricanes larger than the design event used to formulate the nonstructural plan in this appendix, elevating residential structures in the V zone could lead families to occupy their homes during an event that would exceed the design specifications of the construction resulting in total failure of the building foundation or walls and loss of life.

Costs for upgrading building codes is confined to purchasing the new codes from the ICC or other sources and administrative and legal costs for incorporating the codes into the existing municipal and county ordinances. Annual O&M costs for this measure are administrative (enforcement and variances) and local. Since local jurisdictions can charge fees for building permits, their costs to update and maintain the IBC and perform inspections of construction can be recovered.

The revision of existing building codes is a relatively inexpensive method of assuring that new construction, building additions or rehabilitation will be constructed in such a manner as to significantly reduce flood and wind damages to structures in the project area. Since the revision of building codes contributes to reducing hurricane and storm damages they are carried forward into more detailed formulation.

4.5.4 Land Use Regulation and Zoning

Land use regulation, more commonly referred to as zoning, is a measure frequently used by local entities (counties and municipalities) to arrange and regulate various land uses within their jurisdiction. Enactment and enforcement of land use zoning helps to avoid conflicts between uses (i.e. industrial and residential), reduce traffic congestion, maintain property values and promotes other social, economic and environmental objectives.

Zoning of private property, like building codes and other land use regulation is one of the police powers granted to local jurisdictions by the states. This method of land use control has been upheld in the judicial system (State, Federal and US Supreme Court) and has helped to shape the physical, economic and social pattern of many cities and counties in the USA. Local zoning is usually required by state enabling legislation to be preceded by a comprehensive plan for the community or county area that includes an official map or plan of the community's land uses and projected development pattern. Also, significant rezoning of property normally requires a preceding, and approved change in the approved official map in the comprehensive plan.

Title 17 of the Mississippi Code authorizes the dividing of property within any municipality or county into specific zones to accomplish the goals and objectives set forth in the comprehensive plan (or official plan) and to fulfill other purposes as described in the Code. In particular, Section 17-1-7 states *"Except as otherwise provided in Article VII of the Chickasaw Trail Economic Development Compact described in Section 57-36-1, for the purposes set forth in Section 17-1-3, the governing authority of each municipality and county may divide the municipality or county into zones of such number, shape and area as may be deemed best suited to carry out the purposes of Sections 17-1-1 through 17-1-27, inclusive. Within the zones created, the governing authority of each municipality and county may, subject to the restrictions with respect to agricultural lands and farm buildings or structures as set out in Section 17-1-3, regulate and restrict the erection, construction, reconstruction, alteration, repair or use of buildings, structures or land. All regulations shall be uniform for each class or kind of buildings throughout each zone, but regulations in one zone may differ from those in other zones."*

Zones or districts are labeled by the predominant land use type allowed within that zone such as residential, commercial or business, industrial, institutional or public, parks and recreation, transportation, vacant, and open space. Each general use zone can be further divided into density sub-zones (R-1, R-2, C-1, B-1, etc.) denoting units per acre or floor area ratios of each use type. Special overlay zones can be added to the normal zoning pattern to address sensitive environments, architectural aesthetics, economic development, environmental hazards, agricultural or historic issues or developmental programs. Zoning ordinances normally describe the types of uses allowed in each zone or district and prescribe certain other limitations or development requirements for each zone. Zoning ordinances can be used to limit development in certain high-hazard areas or areas with sensitive environmental resources.

Under the umbrella of this state enabling legislation, each of the three counties and 11 municipalities being studied in this report may (and have) established land use zoning ordinances for their jurisdictions to fulfill the goals and objectives of their comprehensive plans. As an example, Figure 8 shows the land use zoning map for the City of Biloxi, MS. The color coding identifies the various land uses (residential, commercial (business), industrial, central business district, waterfront and others) and the interfaces between the uses. In the example below, shades of yellow denote residential uses; red and orange indicate commercial uses and dark blue denotes the Biloxi central business district (CBD) at the Gulf shoreline. The designations of B-1, B-2, RM-10, etc. for each color indicate land use densities such as dwelling units per acre or as an expression of floor area ratio for commercial uses on the parcel.

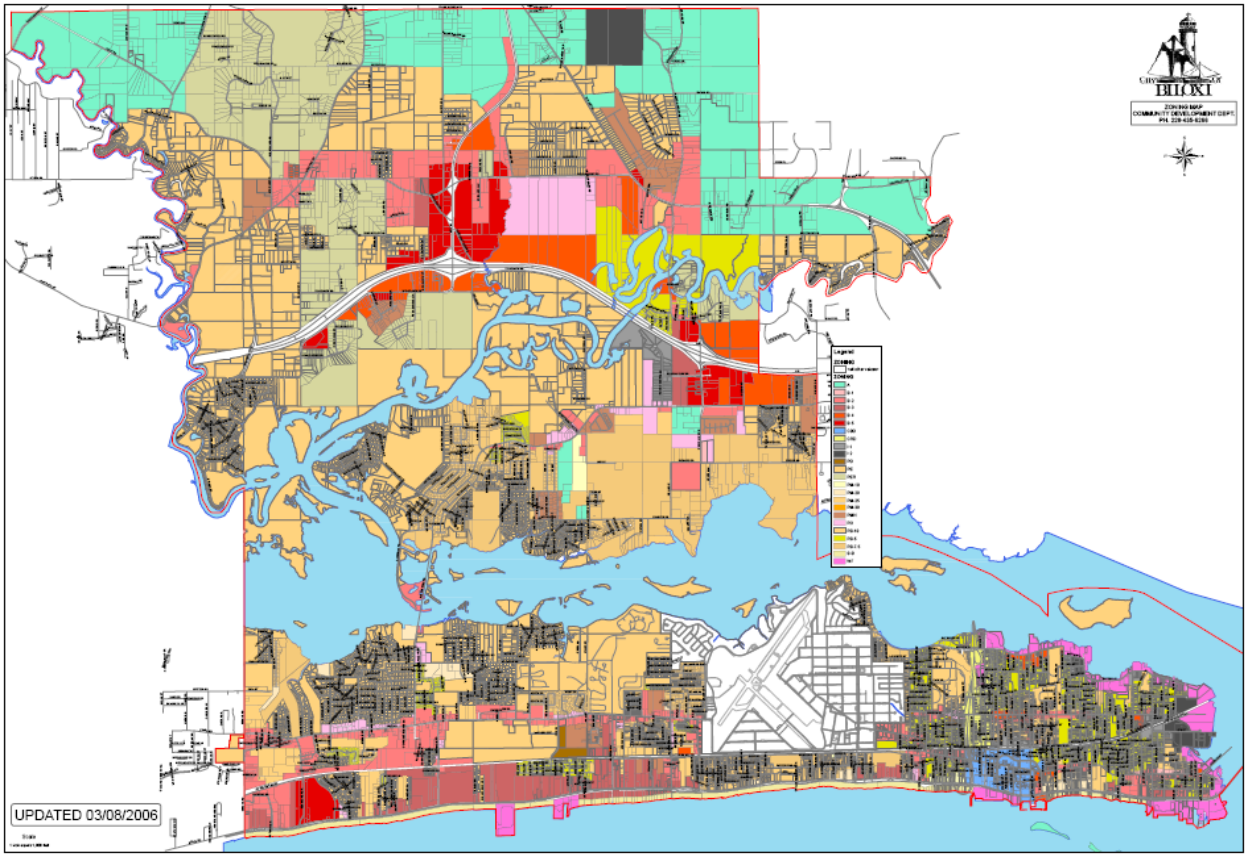

Figure 8. Biloxi Zoning Map

The courts have overturned numerous zoning ordinance determinations by communities and have stricken numerous zoning ordinances where zoning restrictions on private property have literally removed all reasonable use or economic value of the property to its owner. Courts have ruled that such Draconian zoning ordinances constitute a "taking" of private property and require reimbursement of the property value to the owner or retraction of the ordinance itself. Zoning private property that is subject to natural hazards (flooding) such that its value is significantly reduced borders on a taking that may require acquisition of the property at fair market value. See Section 4.5.2 - Floodplain Management, Floodplain Zoning, Flood Insurance and CRS on the application of zoning measures in the floodplain.

Generally speaking, land use zoning or rezoning as a measure for reducing flood damages is largely ineffective in many cases because of the amount of existing at-risk development that has been "grandfathered" into the zoning ordinance at the time of its enactment. These "non-conforming uses" cannot be totally removed through the zoning ordinance process unless they are destroyed (declared unsuitable for occupancy or a hazard) and then reconstruction is possible so long as the new structure and its use conform to the zoning district requirements. Again, overly restrictive covenants on the property would constitute a taking and require compensation of its value to the landowner. Only in the application of floodplain zoning and then only in the case of the regulatory floodway can such absolute redevelopment restrictions be upheld in the courts.

In areas where no development has taken place (vacant land) or where development has been largely removed (total loss areas), zoning or rezoning of the property could accomplish several project objectives. Property devoid of structures only retains its basic land value as dictated by market forces. That land value is influenced to some extent by the natural hazards that may

endanger any development that would be constructed on the property. In the case of the study area, there are vast numbers of privately-owned tracts where the structure has been totally destroyed leaving only a concrete slab or wood pilings from the previous foundation. In these cases, rezoning the property for other land uses more adaptable to and compatible with the natural hazards may indeed accomplish several program objectives.

Zoning of high-risk properties bordering the coast and some of the inlet areas could be used to reduce the incidence of damages to certain types of development or all development. As discussed earlier, overly restrictive zoning that removes all economic opportunity of the property to its owner would be found to be a taking under the 5th Amendment and require just compensation. Attempts to rezone property previously zoned as residential or commercial uses for which the land may bear an economic return for its development or sale to park, open space or environmental uses zoning would raise that red flag of a taking.

Although a single zoning action that would prohibit all development within a specified area along the coast would significantly reduce flood damages in the project area, without full compensation of the fair market value for the property such zoning could be stricken in court. Significantly reducing the density of development from four dwelling units per acre to one dwelling unit per acre may be possible, but a court ruling may still consider that action to be a taking and the current ownership pattern may void any opportunities for actual implementation of such a rezoning change. In effect such restrictive zoning is no different than a complete mandatory buyout of the high-hazard zones.

Another option for rezoning the high-risk coastal and inlet areas may be to recognize the ability of higher density type development (development which commands a higher economic return for the property) to financially meet or exceed the restrictive building codes and extra requirements imposed by FEMA guidelines for development in these high-risk zones. While single-family homes, private-owner motels and chain restaurants generally do not have the financial resources to meet the restrictive construction guidelines or cannot be architecturally adapted to the guidelines, a mixture of high-density commercial and residential units may be able to meet those guidelines and still return a significant economic return to the owners.

Zoning the coastal areas for mixed-use commercial and residential at per-acre densities that would force building construction to be predominantly vertical combined with FEMA guidelines for first floor elevation could result in a number of multi-story buildings perched above parking garages along the beachfront. A mixture of residential condominiums, casinos, retail shopping and other associated uses perched on multi-decked parking garages would allow intensive reuse of what is now largely vacant land except for residential single-family foundation slabs and FEMA trailers.

In addition to reuse of these uneconomic properties, this form of redevelopment would generate significant tax revenues, employment opportunities, windfall profits for existing beachfront landowners and produce a significant structural wind break for development landward of this corridor. The nonstructural team observed these “wind-shadow” effects (as well as surge/wave-shadows) along the coast where more substantial building construction along the beach protected numerous residential and commercial structures located just landward of that building line – in effect a building “line-of-defense”.

More importantly than the potential benefits to intensive use of the beachfront properties through rezoning is the fact that such zoning would not be viewed as a taking requiring compensation. This rezoning would be considered as a financial windfall for existing landowners whose property would become exceedingly valuable to new developers. Similar in some respects to the TDR concept, coastal land otherwise of little value would have far higher value in this new market situation thanks to rezoning. Properties found to have potential for ecosystem restoration as wetlands could be purchased and developed as buffer areas landward of the high-density beachfront and integrated with golf-courses or other passive uses (trails, etc.).

In addition to zoning, another frequently used land regulation mechanism is Subdivision Regulations. These regulations prescribe requirements for the subdivision of land into individual lots for construction of either or both residential and commercial uses. The regulations address design and construction of all land improvements within a subdivision including platting of subdivided land, site grading, drainage, streets, utilities, site hazards, right-of-ways, easements, and lot setbacks. Developers wishing to subdivide land into individual lots for residential and/or commercial use must submit development plans (prepared in accordance with the subdivision regulations) to the Municipality or County where the site resides for approval. Usually both a preliminary plat and final plat that address all of the concerns listed in the regulations must be submitted for approval before any construction may begin.

Subdivision regulations can be modified such that the inundation threats for each lot can be delineated on the developer's submitted plat map and the regulations themselves can place certain restrictions or requirements on the developer to assure that the future landowners within the subdivision are either protected from defined inundation depths or made fully aware on their property map of the potential inundation threat on their lot. Since construction of any subdivision (where such regulations exist) depends upon approval of the submitted plat map by the local government, these restrictions and requirements with respect to inundation threats can be very effective for any new growth in the project area.

Costs for changes to zoning ordinances or subdivision regulations are local, administrative and minimal in nature compared to other alternative measures. Normally, municipal or county planning or engineering staff personnel, or planning commission or zoning board members administer zoning actions (variances, meetings, reviews, etc.) and subdivision application reviews.

Considering the level of control that these land use regulations can assert on the development and use of land within each jurisdiction in the project area, land use regulation (zoning and subdivision regulations) have been carried forward into more detailed formulation of nonstructural plans.

4.5.5 Development Impact Fees, TDR, PDR, and Redirection

4.5.5.1 Development Impact Fees

Communities nationwide use monetary development impact fees to address external costs resulting from land development projects that impact associated community services and amenities. Normally these impact fees address additional loadings on school systems, libraries, infrastructure (utilities, roads, collection services), fire, police and emergency services and other public services that support new development (especially residential and commercial development that use those services most).

Generally development impact fees have been upheld in the courts provided that they are levied fairly by an governmental entity legally able to collect such fees, that they are collected for addressing a legitimate public purpose, and that the method of collection most closely resembles the objective for the fee so as to not approximate a taking. In this case, support of a redeveloped and robust emergency services system that would be applied to many types of hazards (especially hurricanes and floods) would be a legitimate purpose for the fees. As such an emergency facility would be directly related to structures and families living on the flood-prone lots from which fees were collected, the legal nexus would be sound.

These monetary impact fees could be applied to new land development or subdivision development on a per lot basis to address municipal or county costs associated with flood emergencies and the aftermath cleanup in damaged areas. The level of fees assigned per lot would be directly related to the level of flood risk at the individual subdivided lot – greater the flood risk, the higher the fees (i.e.,

V/VE zone - $10,000/lot, A/AE Zone - $8,000/lot, B zone $4,000/lot). Developers of the subdivided sites could reduce the fees by receiving local planning commission approval on specific, bonded measures that reduced the flood hazard on the lots.

Costs for instituting development impact fees are local and administrative in nature.

4.5.5.2 Transfer of Development Rights (TDR) and Purchase of Development Rights (PDR)

Transfer of Development Rights (TDR) and Purchase of Development Rights (PDR) are land use control mechanisms predicated on the concept that landowners' rights to develop their property can be separated from other land rights (mineral, air, surface, etc.) and traded or purchased within a market-like system. Generally speaking any land use controls (zoning, etc.) that significantly decrease the market value of property or remove an opportunity to receive some economic value or use from the property have been considered a taking under the Constitution and require compensation to the landowner. TDR has been found in the nation's courts to be a legal device for transferring that portion of a landowner's rights to the property for compensation in a market-like process that avoids the "takings" issue. As the programs are strictly voluntary in nature, the takings issue is set aside. The ability of local governments to establish and operate either a TDR or PDR program is normally enabled by enactment of state legislation.

In TDR, the landowner's right to develop certain property (sending lot) that may be environmentally sensitive, historic, scenic, prime agricultural land or flood-prone, can be offered as a market item to be purchased (monetary transaction) by other landowners whose land (receiving lot) is not restricted by the same environmental, hazard or historic parameters. Normally the receiving property is provided a density bonus whereby more units of housing or commercial floor space development can be permitted on the same land area with the purchased development rights. TDR programs are popular within the United States and have been used successfully (i.e. Maryland) to reduce losses of sensitive environmental landscapes, historic buildings, and agricultural land or restrict development on hazardous property while allowing land development and the tax revenues associated with growth to increase.

A TDR program can be established by a local unit of government, such as a county within which both the sending and receiving property are located. Based upon documented parameters, sending properties are identified and values associated with the development rights are established. A number of properties in the sending area can be formed into a "sending district". Landowners of potential receiving properties (which are designated as "receiving districts") are given the opportunity to purchase (monetary transaction with the sending landowner) those rights. The owner of the sending property retains ownership of the land but is not able to develop the property under the terms of the transaction. Normally, property taxes on the sending lots are reduced substantially to reflect the loss of potential development. The sale of the development rights is documented on the property deed and encumbers the deed in future land transfers.

Establishment of a TDR program in the project area would require the enactment of state enabling legislation. Examples of that legislation are available from other states and the costs for instituting and operating the program are local and administrative. All other costs are contained within the land development rights transfer market. The establishment of a TDR program was one of the 180 suggestions offered by the public and cooperating agencies.

Purchase of Development Rights (PDR) accomplishes the same objectives as TDR but requires a unit of government (county or municipality) to purchase all or some (development easements) of the development rights of the subject property. Generally the value of the development rights reflects the appraised value of a structure type (residential or commercial) that would be permitted under

existing land use zoning. The value and limited use of the land and its reduced property tax burden remains to the landowner. This development rights purchase program is unlike the TDR program in that the development rights are not resold or traded through a market mechanism, but held in a public trust and used for public uses (recreation, etc.) or left in their present land use (historic preservation, ecosystem, scenic easement). A successful PDR program is operating in Lexington, Kentucky where development rights of horse and agricultural farms surrounding the metropolitan area are being acquired to preserve the scenic quality of the landscape and forestall subdivision development outside of the municipal water and sewer service area. The value of the development rights is being established through a comparison of tax assessments displaying both with and without future development values of the tracts.

As is the case with TDR, a PDR program would require enactment of state enabling legislation. Costs for instituting the program would be local and administrative or could be operated through a non-profit organization. Costs to operate a PDR program would require sizable sums of capital with which to purchase the development rights of vacant lands in the project area. Funds could be secured from the state or through local taxes or assessments to fund the land purchases.

Both TDR and PDR could be used in the project area to acquire development rights of parcels subject to frequent inundation or that are environmentally sensitive. Properties subject to inundation by surge and waves or that are prime ecosystem habitat could be designated as the sending district and property located above the 500 year event or the Maximum Probable Intensity Hurricane surge-plain could be designated as receiving districts. Monetized property development rights could be designated in the sending district and sold by the administrating agency to eligible property owners in the receiving district – a transaction that restricts development in otherwise hazardous or environmentally sensitive areas with compensation provided through a private market process. More dense development in the receiving district would offset property tax losses in the sending district. Tax-sharing agreements between the sending and receiving districts could offset losses in the TDR sending areas.

Since both of these programs are voluntary in nature and are essentially market-driven processes, they are not easily scheduled as other more proscribed measures (acquisitions or floodproofing). Given this characteristic, both TDR and PDR may be more applicable to high-hazard properties that were vacant prior to the Katrina event where development pressures are not as high. These properties are less likely to be redeveloped in a short period of time giving the process time to acquire the development rights. Using either TDR or PDR to restrict development of these properties would accomplish many of the planning objectives without direct Federal expenditures.

Both of these measures should be carried forward into a more detailed nonstructural plan formulation process. Requirements for state enactment of the required enabling legislation would have to precede implementation of the measure by local governments.

4.5.5.3 Land Development Redirection

Land development redirection considers that rational Federal, state, county, municipal, corporate and private landowners when confronted with ongoing natural or man-made threats that result in damages to fixed assets will over time migrate to locations that avoid such continuing losses. In situations like Katrina, where physical damages are catastrophic and there are losses of life, some migration out of necessity would occur at least temporarily. Reconstruction back within hazardous areas does occur so long as the risks of future events can be mitigated or the risks are ignored by landowners due to cultural, social or financial influences. As discussed in Section 4.5.2 above, certain loss off-setting programs such as flood insurance can delay that long-term permanent migration so long as the insurance carrier chooses to continue reimbursements for damages. As is

now evident by the many court battles between landowners and insurance carriers along the coast, that continuing reimbursement for damages may be ending soon.

For public facilities (schools, fire stations, police stations, hospitals, emergency services, public works facilities, etc.) that are: 1) more expensive than residential or commercial uses to repair following damaging events, 2) that need to maintain continual services (some emergency services) to thousands of citizens, and 3) have to be repaired with either disaster mitigation money or local taxes, maintaining such facilities in hazardous areas becomes a burden on the financial and political resources of the community. Both county and municipal governments can, over time, successfully relocate certain public facilities out of hazardous areas through judicious use of funding authority in their Capital Improvement Programs.

Capital Improvement Programs (CIP) are enabled by state legislation and allow local governments to construct new facilities or rehabilitate existing facilities to serve public purposes or in some cases purchase very expensive equipment (vehicles, pumps, electronics, etc.) that would be beyond normal purchase limits under local annual operation and maintenance fund accounts. Local governments establish capital improvement programs based upon approved public facilities plans either through a comprehensive planning process or some other process provided for in the state enabling legislation. Under this CIP, a county or municipality could issue bonds, borrow funds or use tax receipts to fund relocation of public facilities that are located within hazardous flood zones and have been repeatedly flooded or are reaching the end of their useful design life. Generally, substantial redevelopment/relocation of public facilities by local governments is a long-term process due to the high costs involved and the political processes necessary to resolve service area disputes and other social issues.

Although careful exercise of land development policies, regulations and programs (such as the CIP) can result in eventual changes in land use that decrease development in high hazard zones and increase growth in less threatening areas, more direct action can be taken that accomplishes the same objectives in a much shorter time period. Specific actions that redirect growth and redevelopment into less hazardous landscapes can be supported with capital investments in land acquisition and infrastructure development and either Federal or State supported mortgaging assistance.

In a relatively stable housing market such as existed prior to the landfall of Katrina in the project area, new housing starts away from the coastal floodplain were sufficient to handle consumer demands for larger and more amenity-filled homes. Relatively new developments such as Diamondhead and other PUD's away from the coastal floodplain were based upon an exclusive housing market demand and lack of sufficient and affordable vacant land within walking distance of the beachfront.

Prior to Katrina, residential development along the coastal floodplain was required by ordinance to adhere to FEMA regulations and the latest version of the municipal or county FIRM. Following Katrina, the establishment of the Advisory Base Flood Elevation by FEMA, disagreements on insurance settlements, lack of flood insurance and insufficient personal capital have resulted in little redevelopment of destroyed housing along the coast. Katrina and the loss of tens of thousands of homes resulted in a severe housing shortage to accommodate displaced landowners and any new arrivals. The past demand turned overnight into a housing need that did not have sufficient available flood-safe residential lots, infrastructure, construction capital, or mortgaging funds. Fortunately many of the displaced population left the area entirely reducing some of the burden on the already damaged housing market.

In order to address the shortages of available residential lots and selected commercial redevelopment that would support construction of new residences, a government-assisted program (county, state or Federal) of new redevelopment sites could assist in redirecting growth away from

the coast and to flood-safe sites. This method of redirecting growth has been used successfully in other flood damaged areas where the housing market is unable for whatever reason to recover and provide needed replacement units. Adding flood-safe units to the housing market not only opens up additional resources for displaced homeowners to return to the project area but provides relocation housing for those whose property may be purchased as a result of applying either structural or nonstructural measures as part of a Corps project. Increasing the availability of reasonably priced development lots also eases the cost pressure on limited market opportunities.

Numerous redevelopment sites can be selected, planned, designed and constructed at a designated flood-safe elevation that would entice people living in FEMA trailers on property where only a concrete slab remains to move upland and away from future flood damages. Necessary site improvements (land clearing, grading and drainage) and infrastructure (utilities, roads, etc.) would be provided with mortgage assistance available through government-sponsored relocations and housing programs. These types of relocation and redevelopment projects have been successfully implemented in other regions as part of nonstructural and structural projects.

In-fill developments within existing communities that are less flood-prone could help to reduce the social and economic impacts of relocations. Several opportunities for in-fill developments were identified during the community assistance design charrettes conducted in 2005 and 2006 under the Mississippi Renewal Program. These in-fill projects would absorb a number of relocations with floodproofed structures within urban areas featuring existing infrastructure and services. Collaboration with local planning commissions and development authorities for in-fill projects would help to assure successful integration of relocatees into the existing community fabric. Care must be taken to assure that in-fill relocations do not overtax schools or other public services within receiving communities. Section 4.5.9 - Permanent Acquisitions contains a more in-depth look at infill developments as a redevelopment concept.

In some communities such as Waveland, Pass Christian and Bay St. Louis where a mandatory acquisition plan applied to high hazard properties along the coast would result in large scale relocations of the population to less-flood-prone areas, another redevelopment plan may be in order. In these special cases, relocating whole neighborhoods or communities as an intact social entity should be considered. In the absence of planned community relocation, these municipal areas would merely be dissolved in time due to a lack of human resources and a crippled economic base.

Planned community relocations would provide the opportunity to accommodate all existing flood-prone land uses into a flood-safe location in a coordinated way that would maintain many of the basic social and economic associations now thriving in the present community. Developing planned communities could also reduce the impacts of a dispersed population impacting public facilities (schools) and services (police, fire, garbage, etc.) in the destination communities.

The challenges in planning large-scale relocation communities in a developed region center on aggregating sufficient land on which to design a coherent community layout. A review of available aerial photography for the project area shows limited development opportunities of any appreciable scale south of Interstate 10 except for a few isolated parcels. Moving north of Interstate 10, there are opportunities that can be explored for relocation communities. These sites would be investigated in greater detail for their possible use as Housing and Community Redevelopment Sites as an adjunct to the permanent acquisition measures.

Obviously redirection of land development can be more successful in coastal areas that are less urban in character, where sufficient flood-free land is available for the redirected community development to occur and where recent events such as a major hurricane have resulted in significant damages to coastal structures and communities. In areas of the Gulf coast that were not directly affected by Katrina or other recent hurricanes, this strategy would be more difficult to implement given the lack of incentives or necessity to move away from these high-hazard areas. The

inertial forces associated with a non-threatening, highly aesthetic coastal location are formidable. Formulation of protection strategies for these non-impacted, urban areas may concentrate on measures that emphasize protection in place rather than redirection of development.

Costs for redirection of growth in the project area would be substantial. Site acquisition, site improvement and infrastructure costs could range between $25,000 and $45,000 per subdivided lot. Depending upon the number of lots developed and the amenities provided redevelopment communities (500 units) could cost between $10.0 and $20.0 million each. Implementation of this process would take several decades depending upon funding constraints and the willingness of the project participants. In view of the potential for "tiering" of the nonstructural measures, land development redirection would fall into the later tiers of implementation.

Development impact fees, TDR and PDR and Land Development Redirection are all techniques that act as incentives or disincentives to redevelopment in hazardous coastal areas. Because they are proven methods for reducing damages to potential future growth they are carried forward into more detailed plan formulation.

4.5.6 Land Taxation Policies, Special Assessments and Revenue Sharing

4.5.6.1 Land Taxation Policies

The taxation of private property through the *ad valorem* tax process, besides being a method of raising revenues with which to operate county and municipal services, can be used as an economic system of incentives and disincentives for directing land use development. Normally, private property taxes are established based upon categories or classes of land use (residential, commercial, agricultural, industrial, and vacant) and their location within or outside of municipal areas. Property taxes are a reflection of the assessed value (a percentage of fair market value determined by the tax assessor) of the land and improvements and locational aspects of the property. Normally property is taxed at a percentage of its true assessed value. Properties are divided into taxing districts that reflect values and which taxing authorities (schools, services, etc.) apply to that location. Different millage rates are applied to each district.

Property taxes are calculated using millage rates determined by the tax assessor's office. The millage rate is determined by dividing the amount of total revenues needed to operate and maintain county and or municipal services (that portion supported by taxes) by the total assessed value of all property within the county (excluding exemptions) or a particular district. The millage rate or "mill" represents one dollar of tax per $1,000 of value of assessed value on the property. Adjustments to the rates are made based upon the property classifications and units of government (county or city) where the property is located.

Since revenues derived from property taxes are a reflection of the costs of maintaining services that support that property, additional costs for maintaining certain classes or locations of property could be defrayed by increasing the assessments or millage rates applied to those "high-maintenance" properties. In other words as the tax district budget increases due to responses to flood events, the millage rate is adjusted to capture those costs from property taxes. Properties located in flood-prone areas that require a higher percentage of public services for support could be taxed at higher rates to reflect that increased service demand. This economic disincentive on development would in time discourage growth in that area. Likewise, for certain aspects of property maintenance provided by a municipal or county that are cheaper because of their location (flood-safe), taxes on those properties could be lowered as an incentive to encourage building in those safer (less-costly) areas.

Costs to modify tax millage rates are local and administrative/legal in nature. The costs to modify the rates are not as compelling as the public reaction would be to making the changes.

4.5.6.2 Special Assessments

In addition to modifying existing millage rates for property taxes in high hazard areas, special assessments on flood-prone property could be used as a disincentive to further development. In theory, taxes from individual land uses should be set such that the costs of delivering public services to that use are offset by the annual taxes accruing to each parcel. In practice property taxes rarely collect sufficient revenues to fully capture all of those costs, but in situations where a property or properties are subjected to recurring damages (such as flooding) including damages to infrastructure that services that property, those costs far exceed the property tax revenues. In these cases, special assessments can be levied against those properties to capture additional revenues for the higher costs of services delivery, infrastructure repairs or to capture windfall benefits accruing to property due to some public improvement that services that property. A special assessment tied to the higher costs of services delivery in a hazardous taxing district would raise the tax burden on properties in that hazard area and in time redirect growth away from those higher cost properties. The special assessments would be added to the existing millage rate of that tax district to support higher costs of service delivery or repairs to infrastructure. Basically used as an additional revenue producer for the public services provider, special assessments can also act as a disincentive for future growth in hazardous areas.

Like modifying tax millage rates, the costs of enacting special property assessments are local and administrative/legal in nature. The public reaction to the assessments (perceived by many as a tax burden) would be much more problematic.

4.5.6.3 Revenue Sharing

An ongoing malady confronting many municipal governments is the rush of downtown businesses and residential growth to more rural county locations. This shift of property tax revenues from municipal to county areas further exacerbates the plight of deteriorating downtowns. This process has been occurring for many years as new transportation opportunities and development sprawl extend growth into non-municipal areas. The affects on the nation's cities are evident everywhere as the thresholds of commercial and public services for losing and gaining communities are approached. Many unique strategies to mitigate the economic and social effects of these migrations have been implemented across the nation. Those strategies include establishment of metro-governments and revenue sharing.

In the case of the project area, use of TDR, PDR, rezoning, taxation polices, changes in the NFIP, planned acquisitions and relocations, all affective nonstructural methods of reducing damages, would in time gut the economic hearts of the existing cities on the coast. Municipal areas like Pascagoula, Biloxi, Gulfport, Pass Christian, Bay St. Louis and Waveland could experience massive reductions in private property ownership and the taxes produced by that property as development is acquired and/or redirected north towards the I-10 corridor and beyond. In an effort to offset these losses, two strategies are possible.

First is the establishment of metro-governmental structures whereby the county and municipal governments are joined into a more regional structure that can address the equitable delivery of public and social services and more evenly distribute tax revenues collected throughout the new jurisdictional boundary. Metro-governments are used across the nation to address the economic effects of sprawl and migration of business and residential taxes from municipal to county governments. Another strategy that can be instituted to defer the heavy losses of revenues associated with business and residential migration is revenue sharing. Municipal/county agreements could be negotiated whereby all or portions of tax revenues generated by relocated facilities could be shared between the receiving counties and losing municipal governments. Sharing of the tax revenues would enable municipal areas to maintain a minimum level of services to remaining

households and businesses that have not been removed. At a later date when the relocation of the majority of the taxable base has been accomplished, the revenue sharing ceases and the municipal area as a separate jurisdiction is abandoned.

Although revisions to local property taxation rates and special property assessments can be formidable methods of discouraging continued land occupancy in high-hazard areas, they tend to be regressive in nature. Given the wide disparities between the income levels of occupants along the coast, increasing property taxes as a financial disincentive to maintain occupancy in a high-hazard area would fall heavily on low-income and fixed-income households. Low-income residents consistently expend disproportionate shares of their limited income to pay property taxes and other land occupancy costs than do their wealthier counterparts. Using the property tax rates to accomplish changes in the land uses and occupancy of high-hazard areas may result in environmental justice issues with a disproportionate share of the costs falling upon the low-income and fixed-income segments of the general population.

In addition, property tax rates are normally capped at certain levels set by state codes, local ordinances or through popular referendums and substantially extending those limits to accomplish a project objective may entail major revisions to already politically sensitive legislation or ordinances. For these reasons, modifications to the property tax rates and the application of special property assessments to discourage development in high-hazard zones will not be carried forward into more detailed formulation. However, should permanent acquisition and relocations of residential, commercial and institutional structures be part of a final nonstructural or combined plan, measures for sharing tax revenues between the counties and municipal jurisdictions are being carried forward in the formulation process to offset tax revenue losses.

4.5.7 Floodproofing

4.5.7.1 General

Floodproofing is a very broad term that describes an array of building construction techniques that can be used to reduce flood damages to structures. This method of protection can be applied to new building construction or can be applied to existing buildings commonly referred to as retrofitting. Structures of different construction types (wood frame, masonry over frame or solid masonry), sizes, uses (residential, commercial, and institutional) and foundation types (slab, crawl space, or basement) can be floodproofed in one of several ways described below.

Unlike permanent acquisition and evacuation (discussed below), floodproofing measures result in the continuation of the structure's functions on-site in some modified condition so that normal functions of that structure or facility can continue (with post-flood cleanup) shortly after the conclusion of a storm event. Although this rebound capability is a plus for families and communities attempting to recover from a major storm event, the risks associated with the determination of appropriate levels of protection and both design and construction parameters are many. Full consideration of risks and uncertainty in establishing the appropriate level of protection and building design parameters is important in the formulation of the floodproofing measures.

Also important to floodproofing is a reliable and timely flood warning and emergency evacuation program so that residents of floodproofed structures can safely evacuate their protected structures. Generally speaking, occupants of floodproofed structures and facilities should not inhabit the building during a flood event. The uncertainties surrounding the prediction of surge depths, wave heights, and other deadly components of approaching hurricanes and storms are too great to risk weathering such events in an at-risk location. Regrettably when the threat of building failure is greatest, rescue is nearly impossible and any rescue attempt would place responders in extreme peril.

Floodproofing has been used extensively across the nation within government-sponsored mitigation programs, as a component of local floodplain management plans or as a private structure owner initiative for communities in both coastal and riverine situations. Thousands of homes, commercial and institutional buildings along the nation's coasts have been retrofitted or newly constructed so that the first habitable or sales floor (commercial) is elevated above a specified flood level.

4.5.7.2 Floodproofing Types

Floodproofing is generally divided into two types: 1) dry floodproofing where no water enters any portion of the structure, and 2) wet floodproofing – where water (floodwaters or clean water) is allowed to enter some portion of the structure temporarily without damages to the structural components of the building or the contents.

Methods of dry floodproofing include constructing watertight enclosures surrounding the building including veneer walls, applied sealants to existing walls and either ringwalls or ring levees that prevent water from reaching the interior of a structure and its contents. Placing fill materials on the building site as a means of elevating the first floor can also be effective although the NFIP requirements for the use of fill materials on individual lots in V zones is very restrictive (erosion concerns). Several structures in the project area that had apparently been raised on engineered fills withstood the storm event with moderate water damages to the first floor. Ringwalls and ring-levees can also be effective methods of dry floodproofing but calculating the appropriate level of protection is full of risks and uncertainties.

Wet floodproofing can include allowing floodwaters or clean municipal water to enter portions of the structure that are so designed that immersion does not damage flood–resistant building materials or contents. The most common method of wet floodproofing is raising or elevating the first habitable floor of an existing building (a.k.a. retrofitting) or constructing a new building on a foundation that elevates the first floor above the specified flood level. Figure 9 shows an elevated residential structure that weathered the surge and winds of Katrina with minor damages.

Figure 9. Elevated Residence in Project Area

Under the National Flood Insurance Program, that specified flood level is normally referred to as the Base Flood Elevation (BFE) which normally has an annual recurrence probability of 1 percent (known commonly as the 100 year frequency flood event). Structures can be elevated to higher levels providing greater levels of protection and further reducing risks, but the BFE is the minimum level specified by FEMA to be in compliance with the NFIP.

In accordance with the NFIP and regulations promulgated by FEMA, many structures in the project area had been wet floodproofed by elevating the structure on wood pilings, piers, masonry columns and other foundation types thereby elevating the structure's first habitable or sales floor to or above the BFE. Areas beneath the raised first floor whether enclosed or not remained subject to flooding. The majority of structures was residential uses and was wood frame or masonry over wood frame construction. Prior to the arrival of Katrina, these structures were able to withstand other high-water events (surge and waves) generated by less powerful hurricanes and tropical storms with minimal damages. Their survival depended upon the elevation of the first floor and vulnerable residential-type stud-wall construction above the storm surge and waves.

Generally, when structures are elevated to a level where the storm surge and pounding wave action cannot impact the building's first-floor substructure or the first floor walls, their survivability increases dramatically. In an elevated condition, only wind forces become a threat to the structure. Application of hurricane-tested building code construction methods and materials use can reduce wind damages to raised structures.

4.5.7.3 Katrina Damages to Existing Floodproofed Structures

The massive surge and waves associated with hurricane Katrina either swept (lateral forces) or lifted (buoyancy forces) many elevated structures off their foundations or the pier foundation itself failed resulting in loss of the structure during the storm. Although hundreds of residential and commercial structures had been elevated according to acceptable FEMA standards proscribed in the NFIP guidelines, the combination of surge levels far exceeding the BFE and waves transported on the surge into the first floor walls and substructure of those elevated structures resulted in their destruction. Several elevated structures that survived Katrina showed signs of wind damage and inundation damages, but they were largely intact. Figures 10 through 13 show the damages to elevated structures resulting from Katrina.

Figures 10, 11, 12 and 13. Damages to Elevated Structures

Observations of the structural damages due to Katrina indicated that many of the unit masonry construction columns and piers failed resulting in total loss of the elevated structures. Improper design and construction methods may have contributed to some of the failures, but in many cases even what appeared to be well-designed and constructed foundations failed due to the extreme forces brought about by Katrina. In these cases, the proscribed level of protection (BFE) was insufficient to prevent the battering forces of waves and debris from crushing the sidewalls of standard residential construction. In several cases concrete block columns and poured concrete, steel-reinforced cylindrical columns both failed resulting in total building loss. Based upon field observations, driven wood piling and deeply set wood poles seemed to survive the combined forces of surge and waves. In most cases the elevated structures themselves had been destroyed, but the wood post foundation, main supporting beams and cross-bracing survived the storm event. Figures 14 through 17 show these remnant foundations and the extent of damages inflicted by surge and waves.

Figures 14, 15, 16, and 17. Remnant Foundations

4.5.7.4 Floodproofing by Elevation (Raising-in-Place)

4.5.7.4.1 General

Elevating the first habitable or sales floor of a structure above specified flood levels is an effective way to reduce damages to a structure and its contents. This method of floodproofing can be applied to both new construction and existing structures (retrofitting) using several techniques including an extended foundation system or an engineered fill. Extended foundations can be accomplished by the use of pilings, piers, columns, or solid walls. The particular type of foundation used is dependent upon the building construction type (wood frame, masonry), building weight, and height of raise, the location of the building with respect to wave action and surge, and cost effectiveness.

In accordance with NFIP guidelines, solid wall foundations are not permitted in V-zones due to the destructive wave forces that can be brought to bear on wall surfaces resulting in foundation failure. However, solid wall foundations could be used in areas where flood damages would only be caused by inundation of the structure (no waves).

In addition to extending the foundation to elevate the structure, floodproofing requires extension of utilities serving the structure (electric power, water, sewerage, gas, telephone, and telecommunications) and modification of access from the ground surface up to the elevated first

floor. In special cases (handicapped or elderly) some options for assisted access (chairlifts) can be included in the elevation design. Although these associated construction components constitute a smaller proportion of the total floodproofing construction process and cost, they are sensitive to the height of raise and determine the livability of the structure. NFIP regulations for coastal areas allow a maximum 300 square feet on enclosed space beneath an elevated structure for securing access to movable storage and as a utility chase.

Closely allied with retrofitting existing structures by elevation is the concept of "rebuilds" on site. In many cases, existing structures that have been found to be eligible for elevation with regard to the allowable water depths at the site cannot be raised because of structural integrity issues due to storm damages or building deterioration. In these cases, rebuilding a new elevated structure on site may be cheaper than either acquisition or rehabilitation of the existing structure. Successful "rebuilds" accomplish the basic objective of reducing flood damages to structures as well as increasing the value and conditions of the housing stock in the project area. All "rebuilds" are designed and constructed to building code specifications and elevated according to local floodplain management ordinances.

This additional option for landowners makes the floodproofing measure very attractive. Opportunities for "rebuilds" are probably numerous throughout the project area, but without detailed data on the conditions of individual structures, an estimate of their number is problematic at this level of detail. More detailed documentation of eligible structures within the project area would be able to capture the number of these potential rebuilds. Costs for rebuilds have been included in the floodproofing section of this appendix since they are identical to elevating new structures on eligible vacant lots.

4.5.7.4.2 Level of Protection

Floodproofing through elevation of the structure is very sensitive to the selected level of protection and storm hazards of the building site. In coastal V-zones and riverine floodways, floodproofing by elevation is generally to be avoided due to the immense physical forces that moving water can exert on building foundations and both building floor and wall systems. In addition to these dynamic water forces, the presence of water-driven debris adds to the extreme battering that standard residential wood-frame construction can be exposed to during a hurricane. Normal wood frame and masonry on frame building construction cannot withstand the dynamic forces imposed by wave and run-out impacts and surge. Even solid masonry construction built to accepted building codes can sustain significant damages and even experience failure under these extreme conditions.

The determination of the appropriate level of protection is a significant parameter for floodproofing by elevation. The NFIP standard requirement for floodproofing is elevation of the first habitable or sales floor (commercial) to or above the Base Flood Elevation (BFE). Additional elevation of the structure above the BFE, where practical, reduces the probability of damages thus reducing premiums on an owner's flood insurance. Although additional elevation of the structure's first floor above the BFE can substantially reduce insurance premiums and improve community ratings under the Community Rating System (CRS), this additional increment of protection is rarely undertaken by landowners. All of the local floodplain or coastal zone management ordinances in the project area indicate the BFE as the minimum level of protection for structures within the flood zone.

Immediately following Katrina, FEMA published the Advisory Base Flood Elevation (ABFE) mapping for the project area. This mapping displayed a revised BFE for the project area that incorporated the affects of Katrina in the new water surface elevations for the purposes of setting the first floors of new construction along the coast. A number of communities and counties in the project area adopted the ABFE into their existing floodplain management ordinances as interim measures. It was anticipated that revised flood mapping (DFIRM) would be issued by FEMA in the near term.

4.5.7.4.3 Building/Structure Elevation within the Identified High Hazard Zones

Due to the immense forces of high velocity water associated with waves, wave run-out and surge inundation, the nonstructural PDT decided that no floodproofing by elevation would be recommended in the project area for the V/VE zones delineated by FEMA. Observations of Katrina damages within the mapped V/VE zones supports the contention that forces in that zone are too extreme to risk residential building construction – few structures survived intact. More importantly, elevated structures in this area could result in their owners attempting to "ride-out" future storms and risk their lives in the process. At the point where the elevated structure may fail, the conditions of surge, waves and wind velocities would significantly reduce the chances for survival by the occupants. In addition, the lives of emergency personnel attempting to rescue those remaining in elevated structures under hurricane conditions would be placed in extreme jeopardy as well.

In addition to the mapped V/VE zone, the PDT identified an additional zone along the coast referred to in post-Katrina FEMA reports as the "catastrophic damage zone" wherein the majority of insured structures suffered damages greater than 50 percent of the structure value. This linear zone included the V/VE zone but extended further inland from the beachfront. Observations of damages within this zone by the nonstructural PDT confirmed that the majority of the structures within this zone were either totally destroyed (only the slab foundation remained) or the remaining structure had been severely, structurally damaged and would probably be demolished rather than repaired. Due to the extent of the damages caused by surge inundation and wave action in this zone the nonstructural PDT decided that floodproofing by elevation should not be recommended in this area.

Since the FEMA designated "catastrophic damage zone" was directly related to the actual Katrina event itself, the nonstructural PDT decided to duplicate that zone (most prominent in Waveland, Bay St, Louis, Pass Christian, Long Beach, Gulfport and Biloxi) along the entire coast within the project area. Based upon measured distances back from the beachfront in those areas, an 800 foot zone extending inland from the normal tide waterline was applied to the coast in Jackson County as well. The nonstructural PDT decided that floodproofing within this 800 feet wide buffer zone would not be safe due to the extreme forces that could attack elevated structures in this zone. These high hazard zones (combined and designated with the acronym HHZ) are shown in Figures 58 through 62 .

Elevation of structures (residential, commercial and institutional) within the FEMA-designated A and B zones (100 yr and 500 yr respectively) could be supported under the current guidelines for coastal construction. Floodproofing through elevation for structures in the FEMA-designated A and B zones is a nonstructural measure that should be carried into the final planning formulation.

4.5.7.4.4 Building Elevation Limitations and Parameters

Limitations on the height that structures can be elevated are based in part upon several factors including cost to elevate the structure (compared with its acquisition cost), high-velocity wind loading on raised structures, structural stability of elevated buildings, occupant accessibility, visual impacts and architectural suitability. Since the costs of protection measures and alternatives being considered in plan formulation would be compared to identify the most cost-effective solutions, the cost of floodproofing a structure would be compared with the cost to either acquire the structure or rebuild a new elevated structure on the same site. Once the cost to elevate the structure exceeds the cost to either acquire or rebuild a new structure on site, the elevation of the existing structure comes into question just based upon economics.

Powerful natural forces during storms and hurricanes place tremendous stresses on all structural components of the building and its supporting foundation. The elevated structure is positioned between the devastating forces of saltwater from the ocean and the equally damaging forces of high-

velocity winds and wind-driven debris. Numerous structures that survived inundation by surge and waves from Katrina were ripped to pieces by hurricane-force winds and wind-driven debris.

Elevation of a structure above the ground places the building in the pathway of hurricane force winds that are undisturbed by ground-clutter. Trees and other surrounding structures (all ground-clutter) can affectively reduce wind velocities at ground level. Constant winds in excess of 120 mph can destroy most unprotected residential construction. Other than structures that have been built to more recent building codes (post-hurricane Andrew) that account for hurricane force winds, most residential structures are not built to handle high-velocity winds. Older structures that can be elevated probably would require some retrofitting of the structure roof and wall systems and windows to survive in the high-velocity wind environment.

The constant battering of wave run-out and surge-transported waves on the supporting columns/pilings and floor substructure of the building during storm/hurricane events raise concerns of sustainability and safety. Among the many forces at work are scouring around the bases of columns/pilings at the ground surface and impact forces of waves on the columns/pilings themselves. Wave run-out that occurs as storm surge brings breaking waves around the base of the structure can easily undermine columns and pilings as well as slabs exposed to this high-velocity water. Waves borne upon the surge can impact extended columns and pilings resulting in material failures or racking of the supporting structure. Assuring that the buried depths of the columns/pilings is sufficient to reduce failure and installing protected-edge concrete slabs surrounding the columns or pilings can reduce the affects of scour. Impact forces on the supporting substructure must be considered in the cross-section design and reinforcing components of the system. Racking can be addressed with cross-bracing between columns/pilings and perimeter stabilization components.

Tradeoffs between the issues of safety and costs of raising buildings to extreme heights and the ability to maintain vestiges of coastal communities in their current location must also be considered. Accounting for the removal of many existing structures and prohibition of rebuilding many structures in high-hazard wave zones (V zone, etc.) discussed below, overly restricting the height of elevation can result in extensive evacuation of buildings and facilities from communities.

In addition, occupant accessibility (especially for physically challenged occupants) to the elevated home is a critical component of the elevation process. Exterior stairways in excess of 12 steps require intermediate landings per the building code and too many steps make the elevation option too laborious for older occupants. For those structures sited on narrow urban lots, situating access stairways with landings may not be feasible. Structures can be relocated on-site to enable easier access options, but these additional operations also increase the cost to elevate.

For those landowners with physical handicaps, an elevated structure poses significant access problems. Although there are several options for addressing handicapped access to an elevated structure, the costs of installing some of these options can be very expensive and require frequent OMRR&R by the landowner. Basic ADA specifications for access ramps for wheelchair users require a maximum slope of 1:12 or 8.33% for the ramp and intermediate landings every 30 inches of rise. Ramps must be at least 36 inches wide and landings must be at least 60 inches long. Using these component requirements, a wheelchair access ramp would have to be approximately 210 feet long to reach a first floor elevated 15 feet. On narrow urban lots, the use of access ramps for handicapped occupants would have limited application.

Although coastal communities around the nation have a somewhat “different” look visually because of the need for elevation of first floors, there are some limits to the visual quality boundaries of an elevated home or business. The overall dimensions of the structure (height versus width and length) can become unbalanced leading to a visually unpleasant building whose value could quickly plummet on the market. In some cases, community association guidelines or local building codes could prohibit extreme elevation of structures. Elevated residential buildings raised in full increments

of one-story (8-10 feet) keep the visual balance of the structure (depending upon the architectural style) up to three-stories. The relationship of the lot size to the building size and the size/bulk of adjacent structures can also influence the visual quality of the raised structure. Visual quality is a significant criteria in determining the market value of structures, and landowners will take the resulting market value of their home or business into account when deciding to participate or not.

There are a variety of architectural styles present in the project area. Those styles include Acadian-Creole, Victorian, Classical and Arts and Crafts. The Acadian-Creole style is indigenous to the local area, but a few of the styles have been imported from other regions, countries and time periods. The more indigenous architectural styles, styles that were developed in recognition of the potential for flooding may be more conducive to elevation while the more classical styles developed in less flood-prone areas would not be as favorable from an architectural viewpoint to elevation. Structural styles that are traditionally multi-story could probably be raised successfully in one-story increments while architectural styles (ranch style) that are traditionally thought of as one floor would not be as favorable to elevation. Consideration for building massing in zoned areas and building proportions of height to footprint in some styles may dictate special requirements in elevation design. In a voluntary program of elevating structures in place, the architectural style of the home or building may be a determining factor in the landowner's choice of program participation.

Many agencies and local governments have proposed raising structures no more than one story (8-10 feet) while others have advocated 12 feet as a maximum height standard. Normally, the one story rule of thumb was applied so that vehicles could be stored beneath a raised structure, one-story increments look appealing visually and to avoid building materials waste. Issues of cost, accessibility, structural stability and visual impacts have been the focus of debates on maximum heights for elevation.

Guidelines established by FEMA in the recent "*FEMA 550 Recommended Residential Construction for the Gulf Coast"* recommend a maximum height of 15 feet for elevating residential structures along the Gulf Coast. This height recognizes the relationship between forces of moving water and hurricane velocity winds that can affect a raised structure. Proven engineering methods for the design and construction of stable, supporting foundations for structures elevated to 15 feet are included in the FEMA 550 guidelines. Since the guidelines are supported by sound engineering principles and field testing results in extreme conditions, the nonstructural PDT decided to accept the 15 feet maximum height limitation for floodproofing in the project area. The FEMA 550 guidelines can be accessed online at: [http://www.fema.gov/library/viewRecord.do?id=1853]

4.5.7.4.5 Mobile Homes

Mobile homes (a.k.a. trailers) present a unique problem in floodproofing by elevation. Generally speaking, mobile home construction is insufficient to withstand the hurricane force wind speeds that would be encountered by an elevated unit. Although the unit may be raised above the surge inundation limit and largely safe from flooding or waves, the raised unit would be subjected to extreme wind loading such that severe structural damage could occur. Comparatively speaking, standard stick-built and manufactured homes built to the International Building Code (IBC) with provisions for hurricane force wind loading would sustain minor damage in an elevated condition. Expending Federal funds to elevate mobile homes that may be totally destroyed by high winds during a future storm event is an unwise course of action and other options are available.

For this reason, the nonstructural PDT recommends that mobile homes not be elevated in the floodproofing program, but that owners of existing mobile homes that were inundated by Katrina and that could be elevated on site (water depths equal to or less than 13 feet) be given the option of an elevated rebuild using a manufactured home constructed to IBC standards. The manufactured home would be of a similar size to the existing mobile home featuring similar amenities and would be

elevated on a driven wood piling foundation (the cheaper form of floodproofing). Since the floodproofing program is voluntary, owners could choose not to participate in the rebuild option or be purchased in which case they would be offered relocation benefits similar to other structure owners. The preferred option would be to maintain a tax-producing land use within the community that keeps the family connected to employment and schools while upgrading the overall housing stock and reducing future hurricane damages.

4.5.7.4.6 Foundation types

There are a wide variety of foundation types and materials used to elevate structures in the project area. The choice of foundation type is based in part on regulatory requirements, construction and OMRR&R costs, visual quality, building size and weight, architectural suitability, and availability of materials. In many cases, the foundations appear to have been constructed as retrofits of existing homes requiring lifting of the structure to construct the supporting foundation. More recent residential construction observed in the area indicates elevated foundations constructed during the building process and those appear to be more integrated in the design of the building. Figures 18 through 21 show some of the foundation types observed in the project area.

Poured Concrete Piers

Stacked Concrete Block

Concrete Block Enclosure

Wood Post and Piling

Figures,18, 19, 20 and 21. Predominant Raised Foundation Types

There are two main foundation types for elevating structures: open and closed. Open types depend upon numerous upright columns or pilings that support critical bearing points beneath the structure. Typically an array of wood or metal beams and joists attached to the vertical members provide support to the first floor. The open foundation allows water to pass through largely unimpeded resulting in less stresses on the foundation members but everything below the first floor is subject to inundation forces. Where moving water may be present, the open foundation is more favorable. Open foundations also maintain good air circulation beneath the structure allowing for more affective drying following a flood event and less potential for mold and mildew growth where sunlight does not penetrate. As stated earlier, NFIP regulations provide for a maximum of 300 square feet of enclosed space beneath the elevated structure for movable storage, access to the first floor and utility chase. Generally in northern climates where cold air circulation beneath the structure can increase heating demands and require insulation beneath the raised first floor, open foundations are not favored. In milder southern climates, the open foundation does not significantly increase heating requirements, so it is more acceptable.

Many examples of open foundations are present in the project area (see Figures 22 through 25). Closed foundation types depend upon solid masonry walls (poured concrete, concrete panels, unit masonry) or some other enclosing, perimeter wall system that supports the exterior walls of the elevated structure. Structure walls are fastened onto wood sill plates anchored into the masonry wall structure. Perimeter bond-beams can be used to tie the top of a unit masonry wall system together

Figures 22, 23, 24, and 25. Open Foundation Types

to avoid racking of the walls during water or wind stress. Interior posts/columns with a system of beams and joints provide support of the first floor. Enclosed foundations do provide a measure of perceived security beneath the elevated structure and movable storage items are not in plain view of passer-bys. Also, closed foundations reduce airflow beneath the structure which can be a good feature in colder climates, but the enclosed foundation does present several problems. First, the closed foundation does represent a large obstacle to flowing water – an obstacle that can create significant impact forces on the wall surfaces from flowing water or wind. These forces can be offset to a certain extent by allowing the enclosed area to be flooded thus equalizing the pressures on the masonry walls. However, in a coastal zone where wave run-out and waves can begin impacting the foundation walls long before surge inundation fills the enclosed area, these extreme forces can result in wall failure and structure loss. The NFIP does not allow the use of solid perimeter wall foundations for elevating structures in wave impact coastal zones (V-Zone). Figure 26 shows a structure raised on a solid wall foundation. This type of foundation can be used in areas where inundation only would occur and then only when sufficient, automatic equalization of water pressures can occur. In addition to the problems of unequal wall pressures, enclosed, damp foundations (common during wet weather or following a flood event) can lead to the growth of molds and mildews that can be life-threatening and hard to control without good air circulation and sunlight penetration.

Figure 26. Structure Raised on Solid Wall Foundation

4.5.7.4.7 Foundation materials

A variety of materials can be used in open foundation systems. The selection of appropriate materials is based upon criteria such as cost, availability, durability, corrosion resistance, strength, reliability and maintenance. An assortment of foundation materials ranging from wood and steel to unit masonry (concrete block) and poured concrete are present in the project area. Some of the materials weathered Katrina's wrath quite well, others did not perform as expected by the owners. A selection of the foundation types is shown in Figures 27 through 30. By field observation, treated wood pilings (square and round) that had been driven or drilled to a sufficient depth appeared to survive the fury of inundation and waves and wind forces. In many cases the supported structure had been totally lost but the wooden substructure remained intact.

Some of the success of the wood pilings may have been due to inadequate strap connections to the supported structure. Had the strapping been accomplished according to the building codes for hurricane force winds, many more of the piling systems may have failed when the structure was destroyed, but that cannot be confirmed by observations in the project area. Based upon post-Katrina observations and data provided in FEMA technical documents, wood piling driven or drilled to sufficient depth to avoid failure due to scour and adequately braced can be used to elevate structures to the maximum 15 feet height. The nonstructural PDT decided to use driven wood pilings as the basic floodproofing foundation for developing costs for floodproofing. This decision was based upon materials availability, relatively low costs for materials and labor to install and their apparent durability under stress.

Figures 27, 28, 29, and 30. Foundation Materials

In some cases elevated foundations were constructed of steel posts with fabricated steel beams and joists. Several of this type survived the storm event, but in most cases the supported structure was destroyed. Again inadequate strapping between the supporting foundation and structure may have spared the foundation when the structure was destroyed. Other than the high cost of steel posts and fabricated components and their availability in large quantities to support the structures' first floor, steel-based foundations systems would be a feasible alternative.

In a number of cases, reinforced unit masonry (concrete block) columns failed along the coast. Some masonry columns were not reinforced adequately and those failed quickly due to wave

impacts. In some instances, reinforced masonry columns failed with the reinforcing steel bars snapped off or bent at ground level where the column met a concrete footing. Figures 31 through 34 show these failed systems. The nonstructural PDT decided not to use standard unit masonry columns (reinforced or not) as supporting foundations for elevated structures due to the number of failures observed in the field. A modified version of the unit masonry column type is described below and will be used to support existing structures that can be raised.

Figures 31, 32, 33, and 34. Failed Supporting Foundations

During investigations of various elevation techniques and materials for the project, the nonstructural PDT became aware of a unique structure lifting system ("segmented piles") that also provided a reliable open-foundation system for raised structures. The system is based upon concrete unit masonry that is stacked around steel rods and driven by a pneumatic jacking system. The segmented piles are positioned at critical load points under the structure (mostly slab foundations) to assure stability of the structure and to avoid differential settlement of the walls and roof systems in the building. Initially the rods and blocks are driven into the soil using the weight of the structure above and the pneumatic jacking system until refusal. Once that solid footing is achieved, the jacking system then begins to elevate the structure as additional blocks and steel rods are added beneath the structure. Figures 35 through 37 show the installation of the segmented piling system and the final result.

According to the contractors working with the system, this system can provide a safe and durable foundation just using the segmented piles up to four feet of first floor elevation. After four feet of elevation, the contractor reverts the structure elevation to a more standard lifting process using cribbing and steel beam supports. The segmented pilings are then removed to the ground surface

and a concrete, grid-shaped footing with steel reinforcing is poured connecting all of the segmented piling footers and reinforced concrete columns are erected beneath the structure with steel beam supports that assure stability and durability of the structure. Elevation up to the limit of 15 feet can be obtained with this system, but due to the increased cost of erecting the reinforced concrete columns after four feet of elevation, this system would only be used in the program up to the four feet of elevation, after which structures would be placed on driven wood piling.

Figures 35, 36, and 37. Segmented Piles Construction Method

Also prevalent were poured concrete columns (square and cylindrical) with either wood or steel beams supporting joists and tied into the structure floor system. In most cases these materials survived the stresses of water and wind, but at least in one instance this foundation material failed. Figures 38 and 39 show a building location where poured, reinforced concrete columns failed at the base where they were connected to concrete footings. Although the concrete itself performed well, the reinforcing design and connection to the footing may have contributed to the failure. In addition, the supported structure had been destroyed leading perhaps to failure of well-connected foundation members. As all of the columns that failed were oriented in a similar direction, the loss of the structure and columns may have been a combination of wind and wave action on the supported structure. Several new rebuilds along the coast are being supported by poured concrete columns (see Figures 40 and 41).

In addition to the use of wood, poured concrete and steel as vertical support components, these materials can be used as supporting substructure beneath the building. Treated wood beams, fabricated steel beams and cast concrete beams can all be used to support the structure first floor.

Selection of the appropriate material for these supporting elements is based upon cost and design requirements. Using building materials that can withstand the rigors of the saltwater environment, wind-driven rain and stresses is mandatory for elevating structures. All metallic connections and fasteners between extended columns/pilings, supporting beams, lateral bracing and stairways must be able to resist the corrosive forces of saltwater and maintain structural integrity during extreme conditions.

Figures 38 and 39. Reinforced Concrete Columns Failure

Figures 40 and 41. New Concrete Column Construction

4.5.7.4.8 Safety Issues

As in all vertical construction, safety is a paramount concern. Besides the normal safety apparatus and equipment that construction crews may use or wear during the elevation of a structure, there is a constant threat of a catastrophic failure of the temporary supporting members leading to loss of the building and serious injuries or death of crew members. Only qualified, experienced and bonded contractors/builders should be elevating structures. In addition to construction of the supporting foundation, new building construction on elevated foundations places the construction crew as much as 15 feet above the ground surface while working on the new structure. The risks for injury or death due to falls or impacts from falling materials or tools are multiplied during this type of construction. All appropriate OSHA safety standards should be followed during this construction process including the wearing of personal safety gear (helmets and safety shoes) and construction procedures that limit the risks of injuries or death during the elevation of the structure and ensuing construction beneath the raised structure.

4.5.7.5 Floodproofing Design – Residential Construction

4.5.7.5.1 Design Assumptions

In view of the comprehensive nature of this protection plan for the project area and the general lack of information on the characteristics of individual structures, a number of assumptions were made in determining what an appropriate elevation design would be and the approximate costs of elevating residential construction structures based upon that standard elevation design. Those assumptions included:

1. Average footprint size of the first floor of the representative residential structure was 1,600 square feet,
2. Floodproofing of commercial uses within residential-type structures would be elevation in like fashion,
3. Floodproofing of public buildings would be estimated as ringwall construction (see Public Buildings Relocations – Section 4.6) rather than elevation,
4. The maximum elevation of the first floor of any structure is 15 feet above ground level,
5. All structures within the floodproofing area were built upon slab foundations that would have to be adequately braced when lifted onto a new foundation,
6. Foundation type for all existing structures elevated between 0 and 4 feet would be segmented piles,
7. Foundation type for all existing structures elevated between 4 feet and 15 feet would be formed concrete columns.
8. All foundations for elevation where no structure now exists on the property will be driven or drilled wood piling,
9. For the purposes of estimating costs, two categories of raise were considered: 0 to 6 feet of raise and 6 to 15 feet of raise. All eligible structures were categorized into these two groups,
10. Each residential structure has two entrance doors that would require access stairways,
11. A 300 square foot enclosed space would be included under the elevated first floor for storage purposes and utility chase for structures raised at least 7 feet,
12. Repairs or rehabilitation of an existing structure in the elevated position would be minimal and financed by the structure owner or through insurance payments,
13. The structure is DSS in its current condition with adequate sewer, water, HVAC and is structurally sound to elevate,
14. Existing floor joists are of sufficient size and quality to adequately support the structure on the new raised foundation,
15. Floodproofing elevation would require new beams to support the existing sub-floor structural system,
16. All rehabilitation of the structure above the first floor to meet building code standards for hurricane construction will be financed by the landowner or the project sponsor.

17. A separate cost for ADA requirements (access ramp or chairlift) was not included in the basic design package, but costs for step access and the contingency amount should cover these additional requirements.

4.5.7.5.2 Floodproofing/Elevation Design – Residential Construction

For the purposes of this nonstructural plan, floodproofing by elevation is only being implemented in areas devoid of significant wave action. Those areas affected by significant wave action are referred to in this Appendix as “high-hazard zones” and are destined for permanent land acquisition or limitation of development rights under the nonstructural plans. Although the FEMA 550 guidelines do provide information on floodproofing by elevation in the V-zone, the minimum level of protection being presented in the nonstructural plan (an approximation of the anticipated DFIRM BFE elevation plus 2 feet) would not adequately protect an elevated structure in the event of a recurring Katrina-type storm. The impacts of waves on normal residential wood-frame wall construction could result in total failure and loss of the structure and its contents. In addition to the tremendous forces exerted by surge and waves, floating and semi-floating debris from other destroyed structures creates a “battering-ram” effect on standing structures that also quickly leads to structure failure. The visual evidence of damages to standing structures and vegetation (especially trees) from this undulating debris pile was noted throughout the project area. The combination of surge, waves and floating debris resulted in total loss of many elevated structures in Katrina. The following preliminary elevation design and cost estimating information is predicated on raising structures only in areas of surge inundation without significant waves or anticipated debris.

Given the large number of structures in the project area, their diversity of size, type, foundation, use and age, and the limited information available on each structure, the preliminary elevation design and estimated costs were based upon a simplified prototype structure (residential in construction type) and two levels of elevation. A 1,600 square foot structure was selected as the most typical residential structure in the project area. Based upon review of aerial photographs, ground observations and data research, this prototype structure footprint-size was selected as being the most representative of the population of all residential structures.

In view of the preliminary nature of the comprehensive plan and the necessity of further, more detailed technical documentation of floodproofing designs and costs prior to implementation, the heights of elevation were divided into two categories 0-6 feet and 5-15 feet. For existing structures the segmented piling technique was used for cost estimating purposes between zero and four feet of elevation. All foundations for existing structures being elevated greater than four feet were considered to be formed concrete columns. Structures with attached slabs would be elevated with hydraulic jacks and supported by steel beams and timber cribbing. The new foundation would be constructed beneath the raised structure.

Following completion of the new foundation, the structure would be lowered onto the supporting beams and all utilities would be re-connected. In the case where a structure was being raised equal to or greater than 8 feet above the ground surface, a 300 square foot storage space/pipe chase on a concrete slab would be provided in accordance with the FEMA 550 guidelines and local ordinances. New decks and steps for access to the elevated first floor would be installed with pressure-treated wood. Grading around the foundation and lot would smooth any remaining construction scars.

In the case of a property that was considered eligible for elevation (inundation depth less than 13 feet and out of a high-hazard zone), but had no current structure, all elevated foundations would be driven or drilled wood piling. Piling would be 12” in diameter and tapered for driving. Driving depth is estimated to be 40 feet in accordance with the FEMA 550 guidelines. Cross-bracing would be standard practice for all timber piling foundations. In accordance with FEMA 550 guidelines, a 300

square foot storage area/pipe chase was included in the designs and cost estimate for all structures elevated 8 feet or greater.

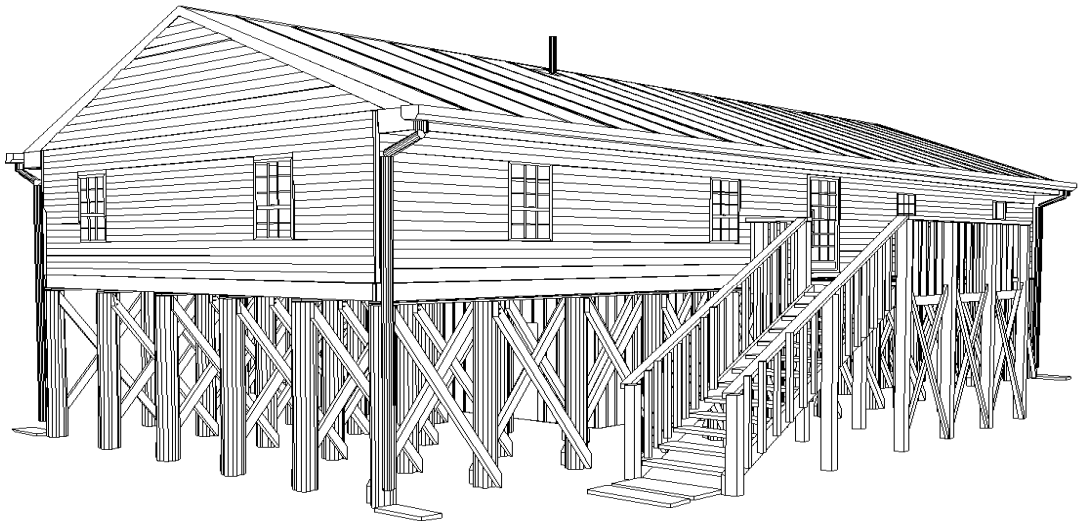
Although any rehabilitation of the structure above the first floor to meet building code requirements for hurricane protection is to be financed by the landowner or project sponsor, hurricane resistant connections (metal strapping and hardware) between the new raised foundation and the first floor substructure (joists or slab) are part of this preliminary design and are included in the preliminary cost.

Using the stated design assumptions, basic elevation designs for the three primary foundation types (segmented piles, poured concrete columns and wood piling) were prepared. These preliminary elevation designs are shown in Figures 42 and 43, 44 and 45 and 46 and 47. Construction materials will be specified according to accepted engineering and architectural practices for coastal construction and in accordance with the provisions included within the FEMA 550 guidelines for floodproofing structures on the Gulf Coast.

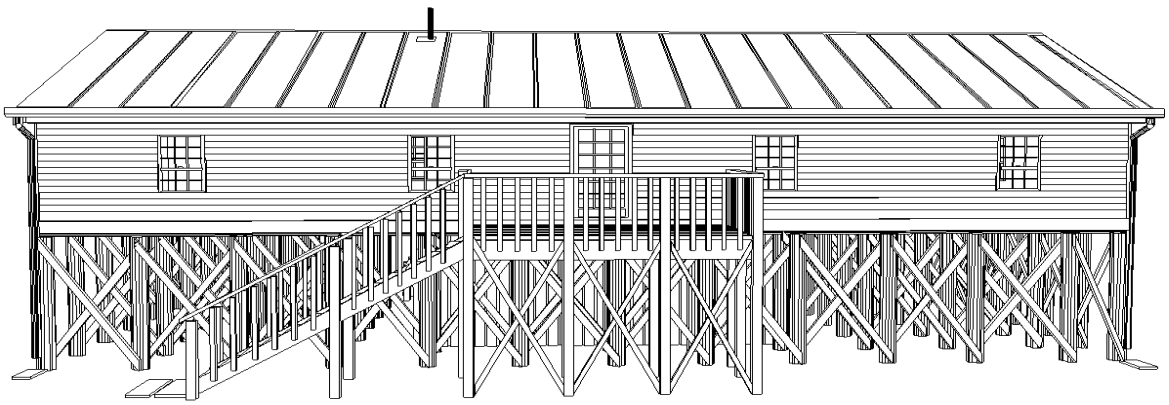
All materials used in the floodproofing work would meet ASTM specifications for construction in coastal areas accounting for the corrosive salt-water environment. Non-corrosive, ferrous connectors, fasteners, steel beams and hardware were used throughout the design and all wooden members used would be pressure-treated materials. All concrete and mortar mixes used in the design would meet ASTM requirements and all utility work (electrical, gas plumbing, HVAC, telephone, and cable) will be installed according to local building codes (minimum IBC 2003).

Prior to implementation of any segment of the identified floodproofing work, more detailed guide plans and specifications would be prepared for each eligible, participating structure with a detailed cost estimate suitable for contract negotiation purposes.

4.5.7.5.3 Floodproofing Cost Estimating – Residential Construction

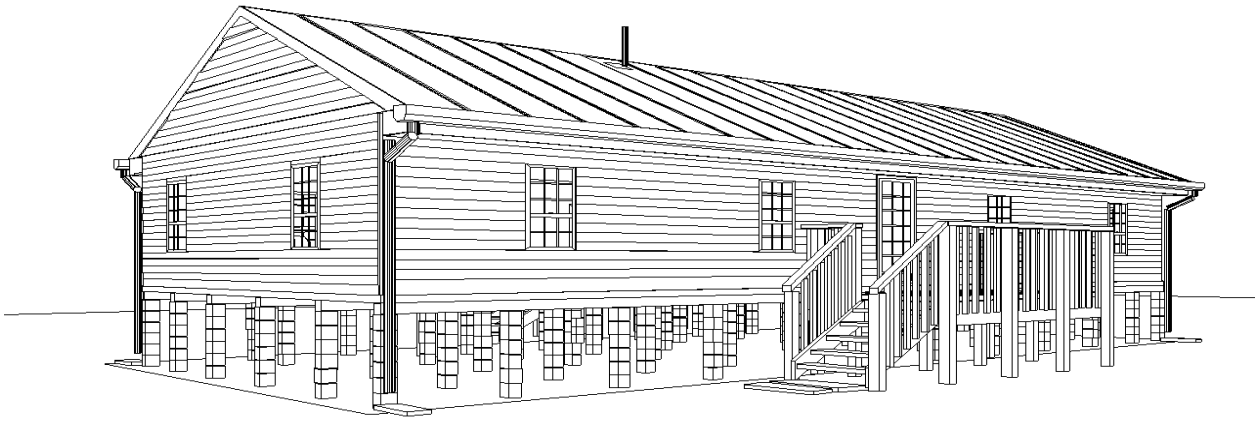


Costs for each of the three primary foundations were based upon the preliminary designs and the assumptions listed above. Since floodproofing contracts are normally negotiated and executed between the structure owner and the contractor (as opposed to a contract between the Government and the contractor), Davis-Bacon wage rates are not required and therefore labor rates in the cost estimate reflect those rates that would be common to the region. Material costs were based upon regional averages for building materials and specialty items. Generally, a 25% contingency was added to all costs unless determined otherwise by the cost engineer. Costs for floodproofing individual prototype structures (structure retrofit and new construction) are shown in the Cost Estimate Appendix.



4.5.7.6 Floodproofing Design – Commercial and Public Buildings

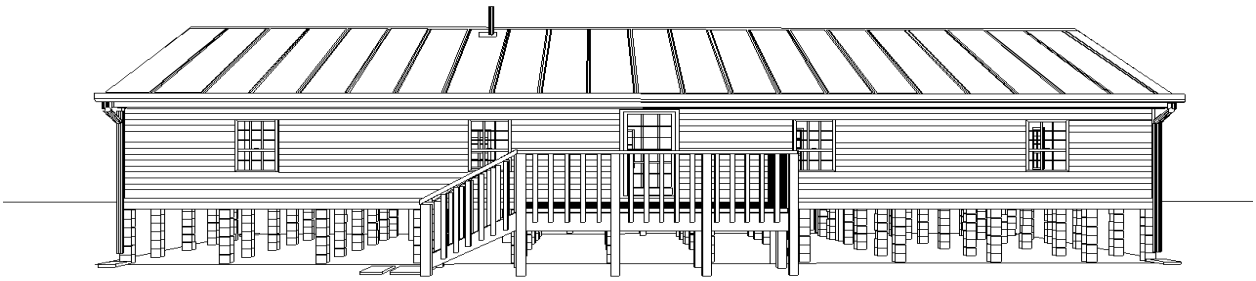
4.5.7.6.1 General



In comparison to floodproofing residential construction through elevation, floodproofing commercial and public buildings is much more complicated due to the need for ground floor access, a much larger footprint size and heavier construction materials (i.e. masonry) in the walls and floors. Commercial and public uses that occupy structures featuring residential-type construction can be elevated according to the techniques, design and costs discussed above. However, commercial sales floors elevated above ground level are not popular with shoppers unless the 2nd floor access is part of a larger raised platform (i.e. elevated mall). For similar reasons, access to most public buildings (significant ADA issues) is preferred at ground level. For this reason floodproofing by elevation for these types/uses of buildings is generally unacceptable to the structure owners and few participate in a voluntary program.

Another major difference is the positioning of the commercial or public building on the lot. Normally residential structures are positioned on the lot with adequate front, side and backyard setbacks (except for the urban residences such as townhouses, etc.) within which construction of various forms of floodproofing can take place. In many cases, commercial retail structures and public buildings are located in more urban settings with minimal setbacks (or no setbacks) from streets, alleys or adjacent buildings. Adequate space for access steps or ramps to an elevated second story is not available on these limited lot sizes.

Figures 42 and 43 – Floodproofing Design – New Structure Wood Piling



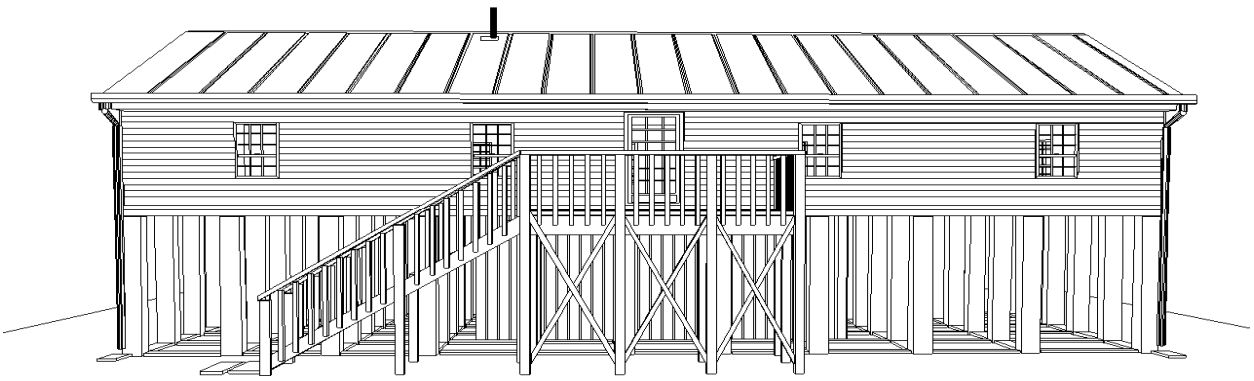


Figure 44 and 45 – Floodproofing Design Segmented Block – Structure Retrofit

Figures 46 and 47 – Floodproofing Design Concrete Column – Structure Retrofit

With these restrictions in mind, other forms of floodproofing such as dry floodproofing must be considered for the commercial and public buildings. Dry floodproofing can take many forms as discussed in Section 4.5.7.2 above. Two of the most popular forms are veneer walls and ringwalls or ring-levees. Veneer walls are constructed as a waterproof layer of dense materials attached directly to the existing structure wall to prevent water-penetration (see more detailed description below). Ringwalls and ring-levees are structural components within nonstructural measures whereby a single structure or complex of allied structures are enclosed with a ringwall or ring-levee structure (see a more detailed description below). In each case, this dry floodproofing technique prevents surge inundation from entering the structure or facility. The primary difference between elevation as a floodproofing technique and this form of protection is the need for closures in the veneer wall or ringwall at structure openings (doors) and the potential need for an interior drainage and pumping system in the ringwall or ring-levee system to remove rainwater due the storm event.

4.5.7.6.2 Design Assumptions

As was the case with residential units, very little specific information has been gathered on the uses, sizes and construction types of the commercial and public buildings within the project area. Generally speaking, they are composed of a mixture of masonry, wood frame and fabricate metal structures. Most of the older public buildings within the urban areas are of masonry construction and are multi-story. Numerous commercial retail and office buildings in Biloxi, Pascagoula and Gulfport are multi-story masonry buildings as well. Newer commercial retail structures located in the sprawl areas and along the major highways (Routes 90 and 29) are generally wood frame construction with masonry surfaces or fabricated metal buildings with various surface finishes. All of the commercial and public buildings appear to be founded on concrete slabs. In view of these observations, the flowing design assumptions were formulated to guide the floodproofing design and cost estimating for these types of structures.

1. The average commercial structure within the project area has a footprint of approximately 8,000 square feet and sits on a concrete slab.

2. Commercial structures can be protected up to 4 feet of water depth by a veneer wall. Costs for that form of protection would be based upon similar installations of veneer walls at commercial structures in LRH.

3. Any flood depths greater than 4 feet at commercial structures would require the use of a ringwall or ring-levee. The costs of that protection method would be capped at the average cost of commercial acquisitions (approximately $2.5 million).

4. Floodproofing of public buildings (schools, fire stations, police stations, city halls, etc.) would be by ringwalls only. Building sizes would be estimated based upon aerial photographs, number of students (square footage) and ground observations. Costs for this form of protection would be estimated based upon indexed values for similar installations at public buildings in LRH. Costs for closures and interior drainage are included in the per linear foot cost.

5. Floodproofing for both commercial structures and public buildings that are of a residential construction type (wood frame on a slab) would be by elevation or ringwall only (wood frame construction cannot support veneer walls).

4.5.7.7 Veneer Walls

One of several methods of dry floodproofing consists of applying a waterproof veneer material immediately against the existing structure wall. In order for landowners to realize the benefits of premium reductions on flood insurance policies, any veneer wall installation must provide at least I foot of protection above the established BFE. The applicability of this method of dry floodproofing depends largely on the structural stability and lateral strength of the receiving wall of the building.

Most residential construction, even masonry brick on concrete block does not have sufficient strength to withstand water pressures above 2 or 3 feet deep. In some cases, heavy industrial or commercial wall construction can withstand greater lateral pressures, but protection above 4 foot depths of water becomes problematic. Un-equalized pressures on un-reinforced masonry walls will soon lead to leaks and possibly catastrophic failures. The waterproof material can range from various sheet polymers, rubber and plastics to concrete. In some cases, constructed veneer walls of high-density, waterproof concrete can be applied directly to the structural walls to provide protection to interior contents. Appropriately sized footers and wall ties provide stability and reliability to the veneer wall structure. Visually pleasing surface treatments can be applied in-situ to poured veneer walls or other surfaces such as brick or stone can be applied to the waterproof concrete structure. Figure 48 shows an example of a veneer wall installation (brick facing) around a restaurant.

In addition to the stability of the structure's walls and waterproofing capability of the material, treatment of closures at existing entrances (doorways, garage doors, windows) into the structure is critical to a successful watertight solution. In veneer wall applications, watertight entrances are affected through casketed, sliding or rolling doors or metal plate inserts in the veneer wall. Although proven designs for these closures are available, none of them are automatic requiring placement by personnel who are on-site immediately prior to or during the flooding event. Annual maintenance of the closure systems is critical to maintaining protection for the structure.

Figure 48. Veneer Wall Installation

Costs for constructing veneer walls on structures varies based upon the perimeter length of the structure, foundation conditions, wall height and number of closures. The NS PDT members have been involved in the design and construction of several veneer walls in nonstructural projects and preliminary costs for this measure can be estimated from those applications. Annual O&M costs for veneer walls relates to inspections of the wall and closures and replacement of gaskets at closures.

Veneer wall costs were based upon information from previous construction of these facilities on LRH nonstructural projects as shown in the above photograph. An average commercial footprint size was determined from aerial photographs and used to estimate approximate costs for commercial floodproofing by this method of protection.

4.5.7.8 Ringwalls/Ring Levees

Another method of dry floodproofing involves the construction of either ringwalls or ring-levees around an individual structure or group of associated structures. Planning and design considerations for ringwalls and ring-levees are similar to any floodwall/levee structure surrounding a community or urban area including risk-based determination of level of protection (wall or levee height), closures at entrances, interior drainage and pumping, geotechnical concerns, foundation design, penetrating utilities, sources of embankment materials and operation and maintenance requirements. Ringwalls can be either of an I-wall design or T-wall design depending upon the soil conditions, footprint restrictions and the height of protection. Normally these ring structures are only applicable to larger commercial, institutional or industrial facilities due to the cost of construction and annual OMRR&R.

Ringwalls can be used to protect schools, medical facilities, and essential emergency facilities. Use of this method of floodproofing is limited on a large scale for residential structures due to restrictions of lot size upon which to align the structure footprint and its cost relative to other options for protection. Generally speaking, these forms of protection are problematic in urban areas where lot sizes are smaller and building setbacks are narrow. Requirements for ongoing OMRR&R and the costs associated with those requirements for these more complex structures also require substantial revenues from the site owner(s).

There would be situations where a ringwall or ring-levee may provide an appropriate level of protection in-place for a critical facility or major employer in the community. On a somewhat larger scale (short of a structural measure), ringwalls and ring-levees may be appropriate for protecting entire neighborhoods of a community or a business or educational complex. In these cases, multiple gate openings in the wall or levee structure require onsite operation just prior to and during a flood emergency and interior drainage and pumping capability can become significant design considerations. Multiple closures and pumping systems require an on-site presence in situations where many surrounding residents may have already evacuated due to the flooding threat. This situation puts operations personnel in great peril should the protection be overtopped.

There are a large number of structures, groups of structures and facilities within the project area that provide critical services to the surrounding neighborhood or community at large. Floodproofing those facilities in-place reduces flood damages and maintains the essential services intact in lieu of relocations to another flood-free site. Opportunities may arise whereby ringwalls or ring-levees protecting neighborhoods could offer protection for valuable infill redevelopment sites allowing at-risk structures located outside the new line of protection to relocate into protected vacant sites. This floodproofing/infill scenario accomplishes the flood damage reduction objectives while minimizing impacts to the socio-economic and environmental justice components of the project area. For these reasons, dry floodproofing through the use of ringwalls and ring-levees will be carried forward into more detailed formulation of nonstructural plans. Figure 49 shows an example of a ringwall protecting a high school and Figure 50 shows an example of a ringwall protecting a commercial structure.

Figure 49. Ringwall Protection for a High School

Figure 50. Ringwall Protection for a Commercial Structure

Capital construction costs for ringwalls and ring-levees can be high depending upon the structure's or complex's perimeter length, soil conditions, height of the wall/levee, material sources, hauling distances, number of closures, interior drainage and pumping requirements, alignment limitations, and wall type (I-wall or T-wall). Among all of the nonstructural measures, ringwalls and ring-levees have the highest potential O&M costs due to the complexity of the structural features and the risks involved in failure of individual components of the protection system. In addition, these protection features require on-site personnel to affect access closures and assure that interior drainage systems (pumping systems) are working prior to the event.

The NS PDT members have been involved in ringwall design and construction for schools and businesses from which preliminary costs have been developed for the plan. Based upon indexed costs for a ringwall (heights ranging between 4 and 8 feet) with closures and interior drainage, linear costs of $3,100.00 per linear foot (included E&D and S&A) of ringwall were used to estimate providing this protection for public buildings.

4.5.7.9. Waveland, MS Pilot Floodproofing Project

In an effort to demonstrate the feasibility and effectiveness of wet floodproofing as a means of reducing flood damages in the project area, a pilot project in Waveland, MS has been formulated as a part of the overall nonstructural program. This pilot project would provide an opportunity to evaluate the technical aspects of the FEMA 550 guidelines as a basis for elevating structures in the program, allow for the public and local officials to see first-hand the application of floodproofing measures by elevating residential structures and affirm Corps cost data and contracting procedures that would support expanded applications of this flood damage reduction method in the MsCIP project area. Given the large number of parcels which would be eligible for floodproofing by elevation and other methods, innovative contracting methods would need to be tested to assure that good quality construction that was both acceptable to the structure owner and that limited the liability of the Corps could be applied in an efficient manner across the project area.

Using available GIS data that displays the ABFE flood levels in the Waveland area and the extent of the high-hazard zones described in this appendix, the NS PDT identified, in cooperation with the Mobile team, a geographic area within Waveland where wet floodproofing would be an effective method of reducing flood damages. This selected pilot area is outside of the identified high-hazard zones where wave action and surge would endanger an elevated residential structure and its occupants. In this initial study phase the ABFE-2 feet was used as the design flood elevation for elevating approximately 25 residential structures. Prior to implementation (if the pilot project is approved), the newest approved local ordinance (City of Waveland local floodplain management ordinance) base flood elevation (or higher) would be used to set the raised elevation of the first habitable floors of the structures. The location of the proposed pilot project is shown in Figure 51.

The 25 residential structures are mainly single-family, wood frame structures on structural slab foundations (two observed crawl-spaces). Many of the residences have a brick veneer exterior. Heights of elevation range between 4 and 6 feet at the ABFE-2 feet inundation level. Using the elevation methods described above, it is anticipated that a combination of the segmented block foundation (0-4 feet high) and the concrete column foundation (> 4 feet elevation) would be used in the pilot project. Project construction would take place over a four year period depending upon the flow of funds. Costs for this method of elevation are dependent upon the footprint size of the structure and the height of elevation. It is estimated that the total, fully-funded cost of the pilot project would be approximately $4.6 M. Upon approval of the pilot project concept a more detailed implementation report would be completed showing detailed cost data, floodproofing procedures, contracting procedures and schedules for completion of the pilot project.

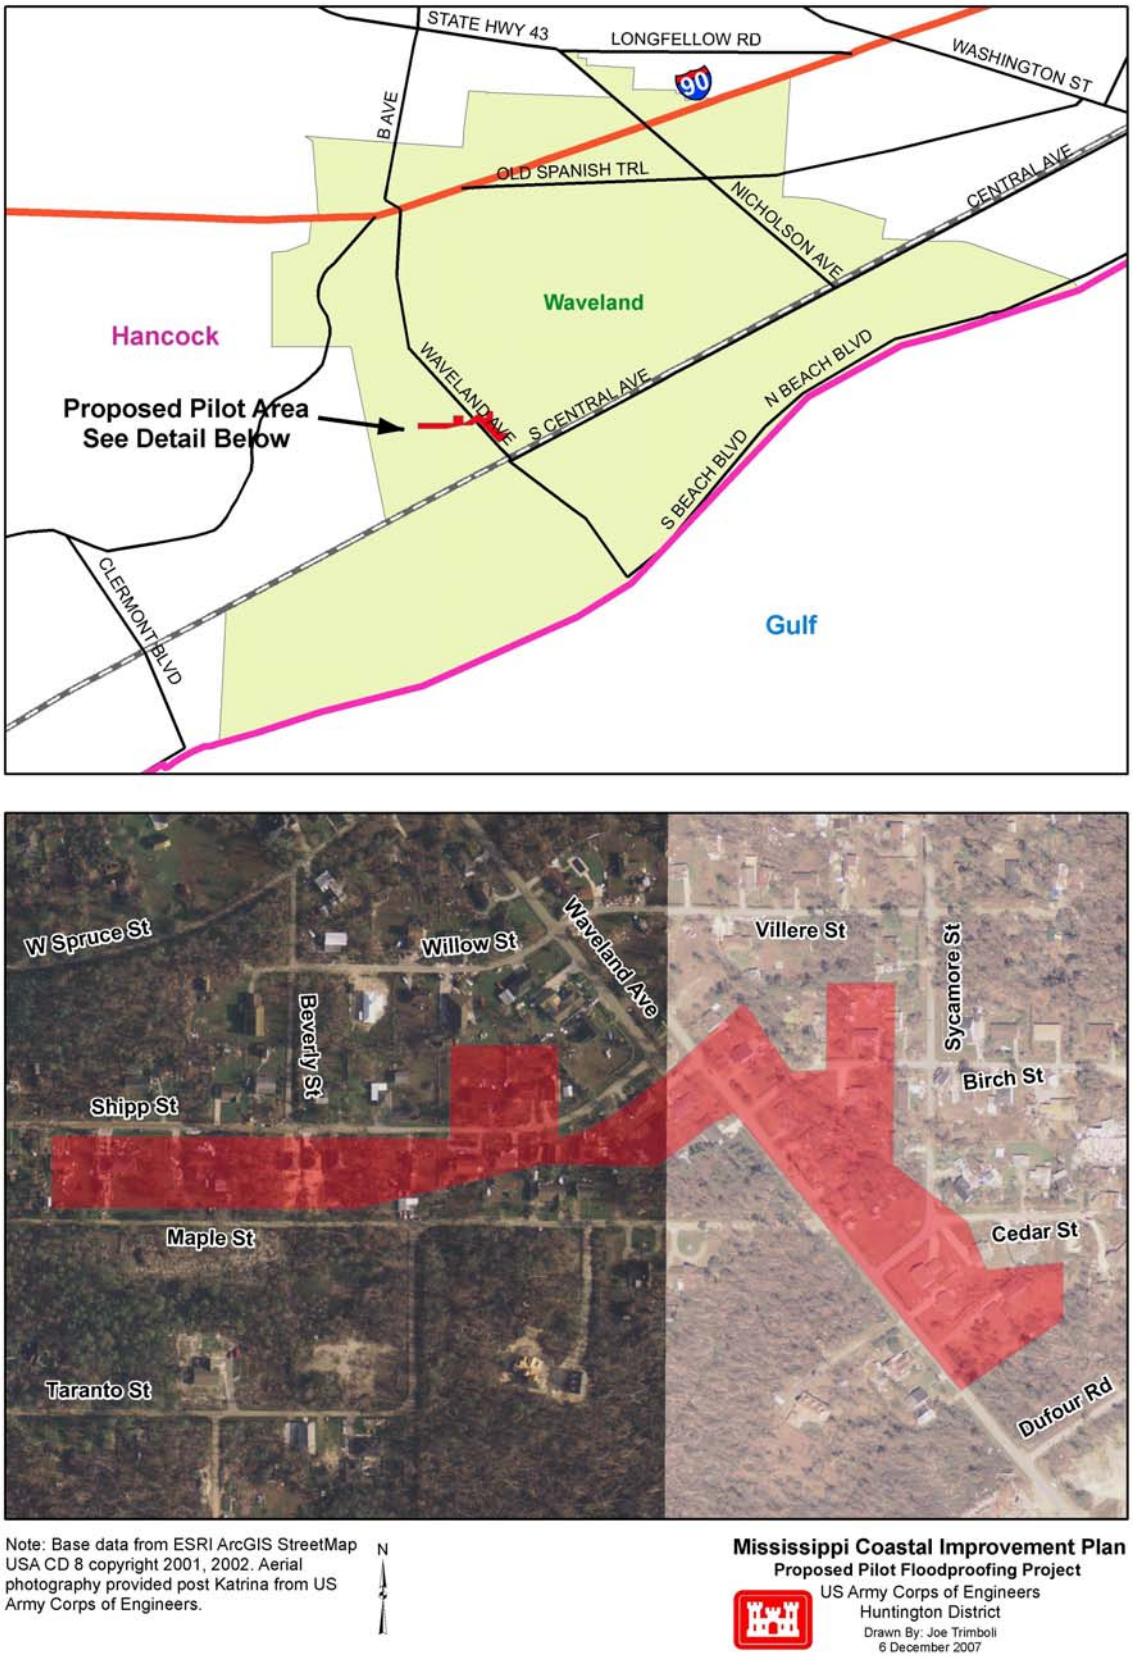

Figure 51. Location of Proposed Waveland, MS Pilot Floodproofing Project

4.5.8. Non-Corps Federal Floodproofing Programs

4.5.8.1. General Program Descriptions.

Following the rescue and recovery operations in the project area, both FEMA and the US Department of Housing and Urban Development (HUD) entered the damaged Gulf areas and began to implement several assistance (grant and loan) programs described in Section 3.5 above. Each of the two agencies has been offering floodproofing (or elevation) grants to eligible landowners so that homes, businesses and public structures (in the public assistance program) could be elevated to reduce future damages. In addition, HUD has been implementing a landowner compensation program that provides up to $150K to eligible landowners within the Katrina surge footprint.
