INTRODUCTION

Objectives

This project is intended to fulfill the needs of the NPS Inventory and Monitoring Program to document 90% of freshwater fishes in Biscayne National Park. This study will also provide useful reference data on the fishes of the southern Miami-Dade County canal system.

Site Description

Biscayne National Park covers an area of 173,000 acres, virtually all of which is shallow subtropical marine habitat (NPS 2004, Figure 1). It also encompasses several offshore islands and a narrow terrestrial fringe along the southern coast of Miami-Dade County. Less than 5% of the park consists of freshwater habitats. Prior to modern water management practices, the mainland coastal wetlands that fringed what is now Biscayne National Park were likely freshwater. The headwaters for these wetlands were lost to urban development and these wetlands are currently marine mangrove habitats. Today, the major freshwater feature in the vicinity of the Park is the Miami-Dade County canal system; several of its canals empty into Biscayne Bay within the Park or in close proximity to it.

These canals are typically several meters deep and have sparsely vegetated, steeply sloping, or vertical banks. They have water control structures near the coast to prevent saltwater intrusion and regulate drainage rates. The canals are unlike any naturally occurring freshwater areas found in South Florida (Loftus and Kushlan 1987). Deep enough to penetrate the aquifer, the canals create a stable and mild thermal regime even during winter cold fronts (Trexler et al. 2001). These facts have probably contributed to the success of introduced species, which are present within the Park in large numbers. Oligohaline, euryhaline and polyhaline species (as per Lorenz and Serafy 2006) also make up a large proportion of the fauna. These species are able to enter the canals when the coastal control structures open, and are subsequently trapped in the canal system.

A second, naturally occurring freshwater habitat may have been sinkholes on the offshore islands (there is no historic evidence whether these habitats were freshwater or saline). However, freshwater upwellings were common in southern Florida prior to water management activities and it is possible that some or all of the sinkholes were spring fed freshwater habitats. However, little attention has been paid to these habitats and their historic and modern conditions are not documented.

METHODS

Sampling was conducted in the freshwater canal system of Miami-Dade County in the fall of 2002 and again in 2003. A total of six canals were sampled each year: Black Creek, C-100, Florida City, Mowry, Military, and Princeton (Figure 1). Each of these canals has a control structure that regulates the flow from the canals into Biscayne Bay. The upstream side of the control structures is always fresh while the downstream side fluctuates between freshwater and marine conditions depending on the operation of the control structure. In order to sample freshwater species we needed to locate our sampling stations on the inland side of the control structures, as the salinity regime on the seaward side is full-strength marine except at times of peak runoff, when the structures are open. Based on their locations, this typically meant that we did not sample within the geographic confines of Biscayne National Park. However, the sampling methodology of this study should give a representative description of the fish populations likely to be present in any freshwater areas of the park.

Our primary means of sampling was by performing multiple 100-meter transects along canal banks using a boat electrofisher. The electrofishing data were supplemented with minnow trap sets, visual surveys, and opportunistic cast netting.

For each canal, a one kilometer stretch near the boat access point was divided into 10 100-meter long electrofishing transects. Transects were further subdivided by designating each bank as a separate transect (north vs. south). This created a pool of 20 possible transects for each canal. Five of these were selected randomly for sampling. The same transects were sampled in both 2002 and 2003 wherever possible. A pollution remediation project in Military Canal limited the area that could be sampled in 2003. Shocking was also conducted in an opportunistic fashion when circumstances dictated.

All specimens were identified to the lowest taxonomic level practical. In nearly all cases, identifications were made to species, although this was occasionally not possible, particularly for visual records. The standard and total lengths of each individual were measured and recorded. Most specimens captured were preserved in formalin and retained as vouchers. Exceptions included individuals too large to practically preserve and some members of the most common species.

Physical parameters recorded at each site included salinity, temperature, dissolved oxygen, and pH. Measurements were made using a Hydrolab 4A Surveyor and Sonde.

Physical and biological data were recorded in the field on paper datasheets. Subsequently the paper records were entered into Excel spreadsheets, and then transferred to an Access database for analysis.

Seven sinkholes on Elliott Key were sampled in December 2005 (Figure 2). Typically, southern Florida's wet season runs from June to November. The wet season of 2005 was typified by above average rainfall and was punctuated by an unprecedented hurricane season with four hurricanes affecting Biscayne National Park. December represents the best opportunity to sample freshwater conditions in coastal areas, for these areas typically have the lowest salinities during that month (Lorenz and Serafy 2006). Sinkholes were sampled using a fish toxicant (rotenone), which causes stunned fish to swim at the surface where they can be easily collected.

RESULTS AND DISCUSSION

A total of 866 individuals of 40 taxa were captured and positively identified during this study, along with an additional three species recorded visually (Table 1). An unidentified Shad species was also visually detected. The 2002 sampling resulted in the capture of 221 individuals of 18 species, while the 2003 effort produced 645 individuals of 32 species. This disparity is related to the use of a larger, more powerful electroshock craft in C-100 and Black Creek canals in the latter year and increased familiarity with the sampling techniques among the technicians in 2003. Because the sampling techniques were more effective at collecting fish in 2003, we can not attribute the observed differences between years to actual differences in fish populations.

Catch rates ranged from a low of 14 individuals in the Florida City Canal during 2002 to a high of 202 individuals in Military Canal in 2003. Tables 2 through 7 show the catch at each station. Military Canal produced by far the largest total numbers each year, despite having only four transects conducted there due to access restrictions in 2003 and mechanical problems in 2002. The reasons for this are unclear, though it may be related to the fact that fishing pressure there is limited relative to the other canals sampled. There are no access points for boats into the canal and it has a reputation for being polluted with wastes from the adjacent Homestead Air Reserve Base, therefore it is not commonly used for fishing. There was also a greater quantity of aquatic vegetation present here relative to the other canals. Apart from the high species abundances found in Military Canal, there was little obvious variation in numbers or species composition between sampling sites. Given the general uniformity of the habitat and the interconnectedness of the canal system, this was not unexpected.

Non-native fishes accounted for 10 of the observed species. They also represented 382 of the individuals, or 44 percent of the overall total catch. The most abundant species recorded during this study was the Spotted Tilapia, *Tilapia mariae*. This species has been observed to be a dominant member of the canal fish fauna in previous studies of the area (Loftus and Kushlan 1987). Other invasive species included Black Acara (*Cichlasoma bimaculatum*), Jewel Cichlid (*Hemichromis letourneauxi*), Mayan Cichlid (*Cichlosoma urophthalmus*), Midas Cichlid (*Amphilophus citrinellum*), Orinoco Sailfin Catfish (*Pterygoplichthys multiradiatus*), Pike Killifish (*Belonesox belizanus*), and Walking Catfish (*Clarias batrachus*). Additionally, two intentionally introduced species were recorded: Grass Carp (*Ctenopharyngodon idella*) and Peacock Bass (*Cichla ocellaris*). The former is a sterile triploid species stocked to control weeds, while the latter has been released to control cichlid populations and provide recreational fishing opportunities for anglers (Shafland 1996).

Fourteen euryhaline species were taken from the canals. They accounted for 217 individuals. Euryhaline species present in our samples included American Eel (*Anguilla rostrata*), Atlantic Needlefish (*Strongylura marina*), Crested Goby (*Lophogobius cyprinoids*), Crevalle Jack (*Caranx hippos*), Fat Sleeper (*Dormitator maculatus*), Goldspotted Killifish (*Floridichthys carpio*), Gray Snapper (*Lutjanus griseus*), Inland Silverside (*Menidia beryllina*), Largescale Spinycheek Sleeper (*Eleotris amblyopsis*), Rainwater Killifish (*Lucania parva*), Common Snook (*Centropomus undecimalis*), Striped Mullet (*Mugil cephalus*), Tidewater Mojarra (*Eucinostomus harengulus*), and White Mullet (*Mugil curema*).

The remaining species were a subset of the native freshwater fish fauna found in natural aquatic environments in south Florida. Cyprinodontoids and centrarchids dominated. The most common freshwater cyprinodontoid was the Bluefin Killifish (*Lucania goodei*). Sailfin Molly (*Poecilia latipinna*) and Mosquitofish (*Gambusia holbrooki*) occurred frequently, and Golden Topminnow (*Fundulus chrysotus*) were also collected. Centrarchid species included Spotted Sunfish (*Lepomis punctatus*), Redear Sunfish (*Lepomis microlophus*), Bluegill (*Lepomis macrochirus*), Warmouth (*Lepomis gulosus*) and Largemouth Bass (*Micropterus salmoides*). This assemblage of native freshwater species is similar to that found in the area by previous researchers (Loftus and Kushlan 1987). Additional native freshwater species recorded include Bowfin (*Amia calva*), Swamp Darter (*Etheostoma fusiforme*), and Shad (*Dorosoma* spp.).

Results of the sinkhole collections are presented in Table 8. It appears that the sinkholes are not a freshwater habitat. We collected only 3 species and all three were polyhaline species. In particular the presence of Mangrove Rivulus (*Rivulus marmoratus*), primarily considered a brackish water fish (Loftus and Kushlan 1987), indicates that these sinkholes are not potential freshwater environs. It is possible that under high rainfall conditions, the smaller sinkholes could become fresh water or that a freshwater lens may be formed on the surface of the larger sinkholes; however, these conditions would only be temporary. The ephemeral nature of freshwater conditions indicates that no true freshwater species would have the ability to colonize the habitat. We concluded that the sinkholes were not freshwater habitats, and, therefore, we did not include *Rivulus marmoratus* in our final list of freshwater species for Biscayne National Park (the other two species found in the sinkholes were already represented from our canal samples).

The best estimates for the total number of freshwater fish species present in freshwater habitats adjacent to BNP range from 30 to 80 species (see Appendix 1). While our results fall within the lower end of this range, many of these potential species are occasional euryhaline migrants or are rare exotics that have been released into south Florida canals but are not well established. Given the extremely limited spatial extent of freshwater habitats within Biscayne National Park, it is likely that only a small percentage of these potential species would occur within the Park boundaries at any given time. As physical conditions change within these freshwater habitats, we would expect the species composition to change as well (Lorenz and Serafy 2006). Therefore we do not believe we collected 90% of the freshwater species that might occur in the Park over a larger temporal scale. We do, however, believe that we collected 90% of the freshwater fish species that occurred within the park during the period 2002-2003. In order to document 90% of the species that may occur in the Park under different condition would require a project of much broader temporal scope. In nearby Florida Bay, it took 8 years of sampling 8 times a year at four locations to capture the freshwater species component of the coastal wetlands (Lorenz and Serafy 2006). Similar (if not longer) time scales and sampling effort would be needed here to capture the temporal changes in community structure within BNP. Clearly, this was well beyond the financial capabilities and limited time frame of this study. For the NPS I&M program to be completely successful in identifying 90% of the freshwater species that occur within BNP on a broader time scale, the NPS can expect to fund a much longer and more costly program including numerous fish collections each year with a project duration on the scale of a decade or more.

Appendix 1: Potential Fish for Biscayne National Park

5 = Present: Collected or seen in study area and expected to still be present

4 = Likely: Found in nearby areas of similar habitat and likely to be present in study area

3 = Possible: Present in nearby areas and possibly found in study area

2 = Doubtful: Present in south Florida with small possibility of occurrence in study area

1 = Unlikely: Present in south Florida, but not very likely in study area

FMNH = Specimen(s) in Florida Museum of Natural History

Species probably in Biscayne NP Study Area (Columns 5+4) =		50		
Species possible in Biscayne NP Study Area (Columns 5+4+3) =		80	High range	

Notes:

- 1: Present in study area (Loftus & Kushlan 1987).
- 2: Present in canals near study area (Loftus & Kushlan 1987).
- 3: Present in ENP (Loftus & Kushlan 1987).
- 4: Present in ENP (Tabb & Manning 1961, Odum 1971) ** Primarily marine.
- 5: ** Has been stocked in Dade county freshwater and may be present in study area.
- 6: Present in ENP (Loftus & Kushlan 1987) ** Few records in south Florida, but has been stocked in Dade county.
- 7: Present in ENP (Loftus & Kushlan 1987) ** No records from coastal canals.
- 8: Present in ENP (Loftus & Kushlan 1987) ** Primarily marine.
- 9: Established in Florida and spreading (Nico <http://nas.er.usgs.gov>).
- 10: Present in canals near study area (FMNH; Courtenay et al., 1974) ** Apparently established in Dade canals, but many may be misidentifications of *Pterygoplichthys*.
- 11: Present in study area (Nico <http://nas.er.usgs.gov>).
- 12: Present in ENP (Loftus pers. comm.) ** Few records in south Florida.
- 13: Present in ENP (Loftus & Kushlan 1987) ** No records from coastal canals.
- 14: Present in ENP (Loftus pers. comm.) ** Few records in south Florida.
- 15: Present in ENP (Tabb & Manning 1961) ** Primarily marine.
- 16: Present in canals near study area (Loftus & Kushlan 1987) ** Primarily marine.
- 17: Present in ENP (Odum 1971; Tabb et al. 1974; Kushlan & Lodge 1974)
- 18: Present in ENP (Tabb et al. 1974).
- 19: Present near study area (Belshe 1961) and ENP (Loftus & Kushlan 1987).
- 20: Present in canals near study area (Nico 1999) ** Present in C-111 and other canals in Dade county.
- 21: Present in canals near study area (Rivas 1962) ** Rare in south Florida.
- 22: Present in canals near study area (Rivas 1962; FMNH) ** Uncommon in south Florida.
- 23: Present in canals near study area (Rivas 1962) and ENP (Tabb et al. 1974) ** Uncommon in south Florida.
- 24: Recorded from Florida freshwater (FMNH) ** Primarily marine
- 25: Present in Florida freshwater (FMNH) ** Primarily marine, *E. harengulus* apparently replaces this species in low salinity waters.
- 26: Present in ENP (Odum 1971; Tabb et al. 1974; Kushlan & Lodge 1974) ** Primarily marine.
- 27: ** No local records, but records of *E. argenteus* in south Florida freshwaters may be this species.
- 28: Present in canals near study area (Hogg 1976)
- 29: Stocked in canals in study area by FWC.
- 30: Stocked in canals in study area by FWC ** Not considered to be established, but some may still be present.
- 31: Present in canals near study area (Hogg 1976) ** Was collected in C-1, but current status unknown.
- 32: Present in C-11, Broward County (Shafland 1996) ** Not known outside of this location.
- 33: Present in study area (Shafland 1995).
- 34: Present in canals near study area (Metzger & Shafland 1984) ** Considered established in the Snapper Creek Canal C-2.

Notes(cont):

- 35: Present in canals near study area (Shafland 1995) ** Present and may be established in the Snapper Creek Canal C-2 and other canals.
- 36: Present in canals near study area (Gestring & Shafland 1996) ** Presently known as far south as C-2 Snapper Creek canal.
- 37: Present in canals near study area (Hogg 1976; FMNH) ** Apparently only established in a small canal near Miami Airport.
- 38: Present in Everglades drainage (FMNH) ** Primarily marine.
- 39: Present near study area (Darcy 1978; FMNH; Pezold & Cage 2002) ** Few records in south Florida, most fish formerly identified as *E. pisonis* actually are *E. amblyopsis*.
- 40: Present in south Florida (Pezold & Cage 2002) ** Only one Florida record currently identified as *E. perniger*.
- 41: Present in Florida freshwater (FMNH) ** Primarily marine.
- 42: Present in ENP (Tabb & Manning 1961; Odum 1971; Kushlan & Lodge 1974; Tabb et al. 1974) ** Primarily marine.
