ABSTRACT

This report summarizes the inventory of mammals of the five park units comprising the Arctic Network (ARCN) of the National Park Service, Alaska Region, between 2000 and 2003. This study was part of a cooperative effort of the Beringian Coevolution Project at the Museum of Southwestern Biology, University of New Mexico, and the ARCN Inventory and Monitoring Program of the National Park Service, Alaska division.

We begin documenting the approximately 39 species of mammals that live in ARCN, with a primary focus on small mammals (i.e., shrews, voles, lemmings, weasels, porcupine, squirrels, and hares). This survey resulted in more than 3,000 primary specimens comprising 23 species.

Small mammal abundance varied considerably between years and across regions. From all the localities sampled in ARCN, two shrew and three vole species were the most frequently captured species, comprising more than 83% of all specimens collected in four field seasons.

This study confirms the importance of ongoing, multiyear efforts to fully document the region's small mammal fauna. Such persistence has paid a large dividend in ARCN with the discovery of five new species in Gates of the Arctic National Park and Preserve, five in Kobuk Valley National Park, three in Cape Krusenstern National Monument, and two in Bering Land Bridge National Preserve. This inventory also extended the distributions of several other species.

These findings, when combined with specimen information gathered from a review of holdings at UAM and other major collections, bring the total number of documented small mammal species to 14 of 16 probable species (87%) in BELA, 13 of 16 (81%) in CAKR, 22 of 22 (100%) in GAAR, 15 of 19 (79%) in KOVA, and 15 of 16 (94%) in NOAT.

The products of this inventory include a large collection of well-prepared, well-documented, and diverse preparations of mammal specimens and associated materials (tissues, parasites, fecal samples, digestive tracts) for taxonomic, zoogeographic, ecological, genetic, parasitological, epidemiological, and other research and management purposes.

EXECUTIVE SUMMARY

This inventory project was a cooperative effort of the Beringian Coevolution Project at the Museum of Southwestern Biology, University of New Mexico, and the Inventory and Monitoring Program of the National Park Service, Alaska division. Other participating institutions included the University of Alaska Museum in Fairbanks; Idaho State University in Pocatello; the University of Saskatchewan in Saskatoon, Canada; USDA National Parasite Collection in Beltsville, Maryland; the Institute of Biological Problems of the North in Magadan, Russia; Sikhote-Alin Zapovednik, a Russian sister-park; and the Finnish Forest Research Institute in Vantaa, Finland. Some two dozen people helped in four summers of fieldwork between 2000 and 2003.

This report details the inventory of mammals in the five NPS units that comprise ARCN. We begin documenting the approximately 39 species of mammals that occur in ARCN, with a primary focus on small mammals (i.e., shrews, voles, lemmings, weasels, porcupine, squirrels, and hares).

The products of this inventory include a large collection of well-prepared, well-documented, and diverse preparations of mammal specimens and associated materials (tissues, parasites, fecal samples, digestive tracts). This survey, which included nearly 650 person-days and 37,500 trap nights of collecting, resulted in more than 3,000 primary specimens comprising 23 species. All primary voucher specimens of mammals were deposited in the University of Alaska Museum in Fairbanks.

Small mammal abundance varied considerably between years and even across regions of the state. From all localities sampled in ARCN, two shrew and three vole species were the most frequently captured species, comprising more than 83% of all specimens collected in four field seasons of effort.

These findings, when combined with specimen information gathered from a review of holdings at UAM and other major collections, bring the total number of documented small mammal species to 14 of 16 probable species (87%) in BELA, 13 of 16 (81%) in CAKR, 22 of 22 (100%) in GAAR, 15 of 19 (79%) in KOVA, and 15 of 16 (94%) in NOAT.

This inventory provided the first specimen-vouchered records of five new species in GAAR, five in KOVA, three in CAKR, and two in BELA. The inventory also extended the distributions of several other species.

Perspectives on the value of the specimen-based approach to inventory and monitoring are discussed, and recommendations for future efforts are listed.

INTRODUCTION

This report summarizes inventories of the small mammals of the five park units comprising the Arctic Network (ARCN) of Alaska's National Parklands: Bering Land Bridge National Preserve (BELA), Cape Krusenstern National Monument (CAKR), Gates of the Arctic National Park and Preserve (GAAR), Kobuk Valley National Park (KOVA), and Noatak National Preserve (NOAT). For this effort (MacDonald and Cook 2002, 2003; Cook and MacDonald 2004) the Beringian Coevolution Project (BCP) at the Museum of Southwestern Biology (MSB), University of New Mexico (UNM), worked collaboratively with the ARCN Inventory and Monitoring Program and the University of Alaska Museum (UAM).

Assessing the biological diversity of life forms has become a priority in the U.S. National Park Service. In response to this challenge, the BCP inventories of the poorly known small mammal fauna of ARCN had two basic objectives:

1. Conduct an inventory at selected sites throughout ARCN to document the occurrence (with a goal of 90% coverage), relative abundance, and general habitat affinities of its small mammal fauna (shrews, voles, lemmings, weasels, porcupine, squirrels, and hares). The effort did not attempt to provide detailed geographic analyses of quantifiable precision because the time frame for this work was much too short given the wide temporal fluctuations in abundance that is amply documented for high-latitude mammals.
2. Provide a large series and variety of permanently preserved materials and associated data sets for taxonomic, zoogeographic, ecological, genetic, parasitological, epidemiological, and other research and management purposes. Because the fauna of Alaska is the least studied of the continent, these NPS inventories are an important contribution to our understanding of mammalian diversity.

METHODS AND MATERIALS

Review of Museum Collections

Documenting species in ARCN was complemented by a review of specimen holdings at the University of Alaska Museum (UAM) and other major collections, primarily the U.S. National Museum (USNM). Scientific and common names of mammals used in this report follow Wilson and Reeder (1993) and Wilson and Cole (2000), respectively. Vegetation classification generally follows Viereck et al. (1992).

Field Studies

Between 2000 and 2003, our field crews established more than 185 trapline transects (Table 1) at 30 general localities throughout ARCN (Figures 1–3). Two dozen people from several countries and institutions were involved (Table 2), sampling ARCN with a total of nearly 650 person-days and 37,500 trap nights of collecting.

Our collecting strategy was designed to maximize the number and diversity of samples by using a variety of methods in available habitats. While particular effort was made to sample rare or undocumented small mammals, the sampling methods used also allowed us to evaluate the occurrence and relative abundance of the more common species.

Diversity of captured specimens was maximized by using a variety of trap types, including snap traps (Museum Specials, rat traps) and live traps (44 oz. plastic drinking cups buried as pitfall traps, Sherman live traps). Several species were sampled primarily with shotgun.

Traplines for shrews and voles were set in the range of available habitats and ecotones in each study location. Traplines typically consisted of 20 or more trap stations per line, with stations spaced 8–10 m apart. At each station, two snap traps or one snap trap and one pitfall trap were typically set within 2 m of each station point. The snap traps were baited with a mixture of rolled oats and peanut butter; pitfall traps were buried flush with the ground and were not baited. Traps were usually set in the late afternoon and checked the following morning. Productive lines were usually kept in operation for two or more nights.

FIELD LOCATIONS

Bering Land Bridge National Preserve

Devil Mountain Lakes (66°23'N, 164°29'W [NAD27]; 16 m elevation). 24–27 July 2001. Thirty-three animals, comprising seven species (including three *Sorex yukonicus* and one *Ondatra zibethicus*) were sampled in a variety of herbaceous and scrub habitats.

Kuzitrin Lake (65°23'N, 163°16'W [NAD27]; 430–460 m elevations). 27–31 July 2001. At this location, we sampled 22 small mammals, comprising five species, in low scrub and graminoid vegetation types.

Serpentine Hot Springs (65°51'N, 164°42'W [NAD27]). 3–11 August 2001. During eight days at this location, 129 small mammals of eight species were collected, including one *Sorex yukonicus*.

Cape Krusenstern National Monument

Igisukruk Mountain (67°08'N, 162°53'W [NAD27]; six traplines from 70–116 m in elevation). 11–14 July 2003. A variety of habitats were sampled in this locality. A total of 174 specimens comprising six species were documented, including tiny shrew.

Kakagrak Hills (67°16'N, 163°40'W [NAD27]; four traplines from 65–230 m in elevation). 6–10 July 2003. At this locality we collected a total of 42 small mammals of seven species, including pygmy shrew and tiny shrew.

Rabbit Creek (67°31'N, 163°35'W [NAD27]). 14–18 July 2001. A variety of scrub and herbaceous habitats were sampled, resulting in the capture of 16 small mammals representing six species.

Red Dog Road (67°37'N, 163°51'W–67°44'N, 163°36'W [NAD27]). 18–21 July 2001. Two areas sampled along Red Dog Road resulted in the capture of 11 animals of five species.

Situkuyok River (67°12'N, 163°10'W [NAD27]). 10–14 July 2001. Our samples from this site on the west bank of the Situkuyok River totaled 14 individuals of six species.

Tukrok River (67°04'N, 163°19'W [NAD27]). 25–28 July 2000. Several herbaceous and scrub sites were sampled here in 2000, resulting in the capture of 45 individuals of four species.

Kobuk Valley National Park

Baird Mountains, Salmon River (67°36'N, 159°47'W [NAD27]; eight traplines from 50–600 m in elevation). 16–20 July 2003. A total of 38 animals, comprising seven species (including Alaska tiny shrew and singing vole) were sampled in a variety of herbaceous, scrub, and open forest habitats.

Akillik River headwaters (67°29'N, 158°14'W [NAD27]; 13 traplines from 200–900 m in elevation). 21–27 July 2003. From this location we sampled 45 small mammals, comprising six species (including tiny shrew and singing vole) in a variety of herbaceous and scrub habitats at various elevations.

Kallarichuk River (67°05'N, 159°47'W [NAD27]); 4–8 August 2001. A number of traplines in needleleaf forest and tall scrub habitats were established near the confluence of the Kallarichuk and Kobuk rivers, resulting in the capture of 64 animals of four species, including *Microtus xanthognathus*.

Kavet Creek (67°07'N, 159°02'W [NAD27]); 5–9 August 2000. Five traplines were established in early August 2000 in a number of forest and herbaceous habitats near the confluence of Kavet Creek and the Kobuk River and at the northeast edge of the Great Kobuk Sand Dunes. This effort resulted in the capture of 146 small mammals of four species.

Onion Portage (67°06'N, 158°16'W [NAD27]); 8–12 August 2001. A variety of forest, woodland and scrub habitats were sampled here, resulting in the capture of 65 animals of six species.

Waring Mountains (67°00'N, 158°29'W [NAD27]); 11 traplines from 53–350 m in elevation). 27–31 July 2003. A total of 116 small mammals of nine species were sampled at this locality, including the pygmy shrew, tundra shrew, tiny shrew, and collared lemming.

Noatak National Preserve

Aniralik Lake (68°12'N, 159°49'W [NAD27]; 227–240 m in elevation). 31 July–4 August 2001. A number of herbaceous and scrub sites were sampled in the vicinity of Aniralik Lake, resulting in the capture of 92 small mammals of five species.

Asik Mountain (67°28'N, 162°13'W [NAD27]); 27–30 July 2001. Base camp was located about 5 km east of Asik Mountain. A mixed woodland and a number of herbaceous sites were sampled, resulting in the capture of 66 small mammals of seven species.

Copter Peak (68°28'N, 161°28'W [NAD27]; 460 m elevation). 24–27 July 2001. Base camp was located about 8 km west of Copter Peak in a variety of herbaceous and scrub habitats. A total of 40 animals of three species were sampled.

Desperation Lake (68°20'N, 158°44'W [NAD27]; 400 m elevation). 10–14 July 2001. Traplines were established in a variety of herbaceous habitats in the vicinity of Desperation Lake with eight animals of three species captured.

Kaluich Creek (67°39'N, 158°11'W [NAD27]; 460 m elevation). 18–22 July 2001. Several upland herbaceous habitats were sampled near this tributary of Cutler River. A total of 57 small mammals of five species were collected.

Kelly River (67°55'N, 162°17'W [NAD27]); 31 July–3 August 2000. A total of 148 small mammals of three species were sampled in open needleleaf forest habitat several km northeast of the confluence of the Kelly and Noatak rivers.

Sidik Lake (68°08'N, 158°59'W [NAD27]; 290–300 m elevations). 14–18 July 2001. Traplines set in a number of herbaceous habitats in the vicinity of Sidik Lake resulted in the capture of 67 small mammals of five species.

Gates of the Arctic National Park and Preserve

Agiak Lake (68°04'N, 152°56'W [NAD27]; 925–1001 m elevations). 11–18 July 2002. A variety of sites were sampled from a base camp situated near the Continental Divide

at this south-draining lake. A total of 271 specimens of five species were documented. Singing voles and tundra voles dominated this collection. The only shrew found at this location was the montane shrew.

Fortress Mountain (68°34'N, 152°57'W [NAD27]; 655–867 m elevations). 27 July–2 August 2002. A total of 158 specimens comprising 10 species were sampled at this far-north National Park wilderness area. Tiny shrew and collared lemming were documented only there, and it was one of two localities where we encountered Alaska marmots.

Lake Tulilik (68°07'N, 154°07'W [NAD27]; 537–747 m elevations). 11–18 July 2002. A total of 228 animals, comprising eight species (including our best series of barren ground and tundra shrews) were sampled in a variety of herbaceous and scrub habitats near the lake, Easter Creek (a tributary of the Killik River), and in the mountain slopes to the south.

Lake Isiak (67°43'N, 156°08'W [NAD27]; 501–664 m elevations). 18–25 July 2002. Base camp was located north of the Noatak River near Lake Isiak. From this location, we sampled 114 small mammals, comprising eight species (including a good series of singing voles) in a variety of lowland and upland habitats.

Nanushuk River (68°16'N, 150°39'W [NAD27]; 943–1032 m elevations). 2–7 August 2002. An Alaska marmot was sampled at this location, along with a good series of tundra voles and a single porcupine. A total of 190 specimens representing seven species was sampled.

North Fork Koyukuk River (67°27'N, 150°51'W [NAD27]; 335–353 m elevations). 18–25 July 2002. We sampled 296 small mammals comprising nine species from a base camp situated near an unnamed lake, which lies west of the north fork of the Koyukuk River and its confluence with Richmond Creek. We found Interior forest small mammal species, including pygmy shrew, red squirrel, meadow vole, and sign of snowshoe hares. We obtained a series of red-backed voles, tundra voles, brown lemmings, and bog lemmings at this location.

Takahula Lake (67°20'N, 153°40'W [NAD27]; 231–242 m elevations). 25 July–1 August 2002. From a base camp located near the lake, west of the Alatna River, 312 small mammals of 10 species were sampled. We found meadow vole and pygmy shrew present and collected a series of montane shrews and tundra voles.

Walker Lake (67°06'N, 154°16'W [NAD27]; 207–271 m elevations). 1–8 August 2002. From a camp on the southeastern shore of the lake, we collected 283 small mammals of 12 species in a variety of forest and tundra habitats. Our only samples of taiga vole were from this location. We also collected pygmy shrew, red squirrel, and porcupine, along with a series of red-backed voles.

SPECIMEN PROCESSING

Each animal sampled was preserved in the form of a skeletal preparation or as a whole-bodied fluid (ETOH) preparation. Some study skins were also prepared. Our crews carried a tank of liquid nitrogen in the field to preserve tissues (heart, liver, kidney, spleen, and lung) and embryos. These frozen specimens were transferred to ultra-low temperature freezers at UAM and MSB and are archived at -70°C . We preserved ectoparasites, and endoparasites from many of the mammals collected. These exceptional data sets will be used to address epidemiological, coevolutionary, taxonomic, and biogeographic questions. Intestinal tracts from shrews were also preserved. Field protocols (Appendix 2) allowed us to rigorously document and preserve specimens.

The primary voucher specimens from this study were accessioned into the mammal collection at UAM and are in process of being curated (Appendix 1). The endoparasite samples are now part of the U.S. National Parasite Collection in Beltsville, MD. Ectoparasites are being identified by a number of qualified experts.

RESULTS AND SPECIES ACCOUNTS

The specific products of this inventory of ARCN's mammal fauna include a large collection of well-prepared, well-documented, and diverse preparations of specimens and associated materials (tissues, parasites, fecal samples, digestive tracts). This resulted in the collection and preservation of more than 3,000 primary specimens of 23 species (Table 3 and Appendix 1).

Two shrews (cinereus shrew, montane shrew) and three voles (northern red-backed vole, tundra vole, singing vole) were the most frequently captured species of ARCN (294, 165, 905, 758, and 629 specimens, respectively; Table 4). They comprised more than 83% of all specimens collected in four field seasons.

This study, when combined with previous efforts and with information gathered from specimens at UAM and other major collections, increased the total number of vouchered small mammal species as follows (see Table 4 and Figure 5 for comparison of park units statewide):

- BELA: 14 of 16 probable species (87%). Two species still to be vouchered from this park unit are ermine and porcupine.
- CAKR: 13 of 16 species (81%). Still missing are ermine, least weasel, and porcupine.
- GAAR: 22 of 22 species (100%).
- KOVA: 15 of 19 probable species (79%). Still missing are ermine, least weasel, muskrat, and snowshoe hare.
- NOAT: 15 of 16 species (94%). Only the Alaska marmot remains undocumented.

SPECIES ACCOUNTS

The following accounts summarize information on each terrestrial species known or suspected to live in ARCN. Data on all specimens are listed in Appendix 1 and are available in greater detail on UAM's mammal collection website (<http://arctos.database.museum>).

Order INSECTIVORA—Shrews

Family Soricidae

Sorex cinereus, cinereus shrew

We captured more cinereus shrews than any other species of shrew in ARCN. Cinereus shrews were found in all major vegetation types (Table 5), but were relatively most abundant in open forest and scrub habitats. Pitfall traps accounted for most shrew captures. The cinereus shrew is the dominant shrew in many communities throughout its range in Alaska. High population densities and wide habitat use of the cinereus shrew may be responsible, at least in part, for the lower abundance of other shrew species (Wrigley, Dubois, and Copland 1979). This shrew was most numerous and was the dominant member of the region's small mammal community in 2003 (Figure 6).

Understanding the evolutionary relationship and taxonomy of this wide-ranging shrew with that of the barren ground shrew of northern and northwestern Alaska has been problematic (van Zyll de Jong 1991; Demboski and Cook 2003). The series of specimens gathered in ARCN, where the two shrews are in contact, is helping clarify this long-standing issue (Waltari and Cook, in prep.).

Sorex hoyi, pygmy shrew

This generally uncommon species was previously found scattered throughout central Alaska, with the closest record coming from a forested site in the upper Kobuk River valley in the Kobuk Preserve Unit of GAAR (Swanson 1996, UAM). New northern locality records from this study are from farther up the Kobuk River drainage near Walker Lake and in the Yukon watershed at Takahula Lake and North Fork Koyukuk River.

Our capture in 2003 of seven pygmy shrews in CAKR and three in KOVA document for the first time this species in these park units and constitute a significant range extension of this boreal species in Alaska.

Sorex monticolus, montane shrew

This species has been documented in all ARCN units and is at the northwestern edge of its range. In 2002, montane shrews accounted for the majority of shrews sampled in GAAR, with the largest number of samples coming from Lake Takahula (42 specimens) and Agiak Lake (29). Overall, the majority of captures of this shrew were in scrub and open forest habitats.

Sorex tundrensis, tundra shrew

Small numbers of tundra shrews were sampled at nine localities in four park units in 2000 and 2001. They were found in a diversity of vegetation types but were most abundant in open forest and woodland communities.

In 2002, 28 tundra shrews were sampled at four localities in GAAR. The largest series of specimens (13) came from riparian habitats at Tulilik Lake.

We captured this shrew, a holarctic species by some authors (e.g., Junge, Hoffmann, and Darby 1983; van Zyll de Jong 1983; but see Rausch and Rausch 1993), only at Igisukruk Mountain and the Waring Mountains in 2003. As in previous years, this shrew proved to be localized and scarce.

Sorex ugyunak, barren ground shrew

The taxonomy and distribution of *Sorex ugyunak* have been problematic. The barren ground shrew was formerly included as a subspecies of *Sorex cinereus* (e.g., Hall 1981), but van Zyll de Jong (1976, 1991) provided arguments for considering *ugyunak* distinct from *cinereus*.

Dr. N. Dokuchaev, Institute of Biological Problems of the North, Magadan, Russia, and participant of this study, confirmed the identities of six *ugyunak* sampled in three ARCN park units in 2000 and 2001. None was collected in KOVA; however, Dr. Dokuchaev has confirmed the occurrence of *ugyunak* in the Kobuk River valley from a UAM specimen that was taken just east of KOVA near Ambler. Finding this shrew in BELA (along with several other UAM records from elsewhere on the Seward Peninsula) indicates a significant range extension. The preference of this high arctic species for moist-to-wet sedge grass tundra and thickets of willow and dwarf birch (Bee and Hall 1956; van Zyll de Jong 1999) is consistent with our findings (Table 5, Figure 4).

In 2002, we sampled 23 barren ground shrews from four of eight localities in GAAR, with the largest series of specimens (15) obtained from pitfall traplines at Tulilik Lake. Our specimens from Takahula Lake are the first records of this species in the Yukon River watershed.

In 2003, 11 barren ground shrews collected from three localities in KOVA provided the first documented records of this species in this park unit.

Sorex yukonicus, Alaska tiny shrew

Four tiny shrews were captured in pitfall traps at two localities in BELA in 2001. Three of the four were taken in low scrub vegetation near Devil Mountain Lakes; the other was captured in similar habitat near Serpentine Hot Springs. The tiny shrew is a new species to BELA and the Seward Peninsula. These captures show a major range extension. Before this inventory, only 12 specimens of *S. yukonicus* were known (Dokuchaev 1997; pers. comm. 2001). By 2003, 37 specimens were secured in a wide variety of habitats across Alaska, including eight National Park Service units in three networks.

A single tiny shrew collected at Fortress Mountain documents this newly described species for GAAR and is the first record of it on Alaska's North Slope. The capture in

2003 of three tiny shrews in CAKR and two in KOVA added a new mammal to each park's checklist. All were taken in pitfall traps set in scrub habitats.

Order CARNIVORA—Carnivores

Family Canidae

Alopex lagopus, arctic fox

This arctic species lives along the arctic coast of Alaska as far south as the northwestern shore of Bristol Bay, with individuals occasionally found considerable distances inland (Manville and Young 1965; Chesemore 1968; ADFG 1978; Bailey 1993).

During our inventories of ARCN, this fox was encountered only at Kuzitrin Lake in BELA. Preserved specimens of arctic foxes are from Hammond River near the eastern border of GAAR (UAM) and in the vicinity of Anaktuvuk (USNM).

Canis latrans, coyote

Coyotes are said to have arrived in Alaska sometime around the early 1920s (Rearden 1981) and reaching peak numbers about 1940 (Dufresne 1946). Coyotes were not observed or reported during this study. There are only two preserved specimens from this region. One is in the USNM and was taken from Kotzebue in 1938. Another is in the UAM and was taken in GAAR, trapped near the confluence of John River and Hunt Fork in 1991. Gardner (1974) claimed to have seen tracks of this species in the Noatak River valley.

Canis lupus, wolf

Wolf sign was reported by our crews in BELA, GAAR, KOVA and NOAT.

Vulpes vulpes, red fox

Red fox were noted at Asik Mountain in NOAT, Kallarichuk River in KOVA, Situkuyok River and Red Dog Mine Road in CAKR, and at Kuzitrin Lake in BELA. In 2002, individual red foxes were seen at Agiak Lake, Fortress Mountain, Lake Tulilik, and Lake Isiak in GAAR.

Family Felidae

Lynx canadensis, Canada lynx

This cat was not seen during this study, and no specimens have been preserved from BELA, CAKR, KOVA, or NOAT. ADFG (1978) considers the forests of the lower Noatak and Kobuk river systems prime habitat for this species.

Lynxes are known to live in forested areas of GAAR, particularly along the Koyukuk River (ADFG 1978), where snowshoe hares, their preferred prey, are periodically found in abundance. The USNM has a lynx specimen from the upper John River.

Family Mustelidae

Gulo gulo, wolverine

A lone wolverine was seen near the Kobuk River while we were traveling between Kallarichuk River and Onion Portage. This was our only encounter with this holarctic and wide-ranging species during this study.

Because of recent efforts by NPS staff, UAM and MSB now have a series of wolverine specimens from ARCN. These specimens were used in a recent molecular study (Tomasik and Cook 2005), which found relatively low evolutionary divergence between Eurasian and North American haplotypes. This study did not support the hypothesis that the Bering Strait divided two distinct species of wolverine. In North America, populations were distinctive only in Southeast Alaska, the Nunavut area in northern Canada, and, to a more limited extent, the Kenai Peninsula.

Lontra canadensis, northern river otter

No river otters or their sign were observed or reported during this study, and no specimens have been preserved from any park units in ARCN. UAM has a river otter specimen from the Dietrich River near the eastern boundary of GAAR.

This species is apparently found in the lower and middle Noatak River and the upper Kobuk River (ADFG 1978). ADFG (1978) also reported this species as numerous along the Koyukuk River floodplain.

Martes americana, American marten

No marten were seen or reported during this study. Marten live in almost all of the Kobuk River drainage and all of the forested area of the Noatak River valley (C. T. Seaton, ADFG, pers. comm. 2003). The animal's status on the Seward Peninsula needs clarification. The forested reaches of the Koyukuk, John, and Alatna rivers of GAAR undoubtedly provide excellent habitat for this species. The U.S. National Museum has marten specimens from Narvak, Selby, and Nutuvukti lakes in the upper Kobuk River drainage.

Mustela erminea, ermine

Ermines were not seen or reported during this study, but specimens of this holarctic species from BELA, NOAT, and GAAR have been preserved in museum collections.

Mustela nivalis, least weasel

Least weasels were not collected or observed. The species is generally uncommon and sparsely distributed throughout much of its holarctic range. It occupies a wide variety of forest and tundra habitats but favors meadows, marshes, and riparian situations, where small rodent prey are abundant (Banfield 1974). Specimens have been preserved from BELA, GAAR, and NOAT.

Mustela vison, American mink

No sightings or sign of this species were noted during this study. Very limited numbers probably live in all ARCN park units, but especially in the Noatak and Kobuk river drainages (Dean and Chesemore 1974; Gardner 1974) and along the major south-slope rivers of GAAR. Mink have been documented with specimens in all units except CAKR.

Family Ursidae

Ursus americanus, American black bear

Two black bears were seen from the air near the Great Kobuk Sand Dunes in 2003. Although this species is known to live in the Kobuk River drainage (Dean and Chesemore 1974), this region still lacks specimen documentation. Black bears were also reported from areas around North Fork Koyukuk River and Takahula Lake in GAAR. The USNM has a specimen from the Brooks Range near the head of John River.

Ursus arctos, brown bear

Brown bears or their sign were reported in NOAT, BELA, and KOVA from Desperation Lake, Copter Peak, Asik Mountain, Serpentine Hot Springs, Kallarichuk River, and Onion Portage. Specimens have been preserved from BELA and NOAT. Brown bears were also reported from GAAR at Agiak Lake, Lake Tulilik, Lake Isiak, and Walker Lake. Specimens have been preserved from a number of locations in this park (UAM, USNM).

Order ARTIODACTYLA—Ungulates

Family Cervidae

Alces alces, moose

Our field crews in 2001 reported moose and their sign at Sidik Lake, Asik Mountain, Kallarichuk River, Onion Portage, and Situkuyok River in NOAT, KOVA, and CAKR. Moose were noted in GAAR in 2002 at Agiak Lake, Lake Tulilik, and Walker Lake, and in CAKR and KOVA in 2003 at Igisukruk Mountain, Salmon River, Waring Mountains, and along the Kobuk River in the vicinity of the sand dunes.

Rangifer tarandus, caribou

In 2001, caribou sign was seen at Desperation Lake, Copter Peak, Aniralik Lake, Kallarichuk River, Situkuyok River, Kuzitrin Lake, Serpentine Hot Springs, and Onion Portage. In 2003, caribou or their sign were seen in GAAR at Lake Isiak, Fortress Mountain, North Fork Koyukuk River, and Agiak Lake (skull found). The Arctic herd occupies much of northwestern Alaska. In recent years this herd usually winters south of the Brooks Range, often as far south as the base of the Seward Peninsula, the middle Koyukuk River, and the Ray Mountains, and as far east as the Wiseman area, where overlap sometimes occurs with the Porcupine herd of northeastern Alaska (ADFG 1973).

Family Bovidae

Ovibos moschatus, muskox

In 2001, muskoxen were noted in CAKR at Situkuyok River. In 2003, a herd of 20 muskoxen was observed near the Kakagrak Hills landing strip in CAKR between 6 and 8 July 2003.

Muskoxen were transplanted to Cape Thompson on the northwest Arctic coast and on the Seward Peninsula in 1970 (Burris and McKnight 1973). By 1990, the northwestern population was estimated to be 130 animals, and the Seward Peninsula population to be 700 animals (Smith 1994). The current status and distribution of muskoxen throughout ARCN needs clarification.

Ovis dalli, Dall's sheep

Dall's sheep were not noted in 2000 or 2001. In 2002, Dall's sheep were seen in the mountains of GAAR near North Fork Koyukuk and Nanushuk rivers. In 2000, a dozen sheep samples were collected in GAAR in the vicinities of upper Contact Creek and Hammond River and deposited at UAM.

Dall's sheep are widely distributed along the length of the Brooks Range (Bee and Hall 1956; ADFG 1973). They are distributed erratically in the Baird and Schwatka mountains (Dean and Chesemore 1974), with sightings reported from the headwaters of the Eli River, between the Cutler and Ambler rivers, and near Howard Pass (Gardner 1974; Dean and Chesemore 1974). Dean and Chesemore (1974) noted that sheep are rare in the Baird Mountains east of the Salmon River.

Order RODENTIA—Rodents

Family Sciuridae

Marmota broweri, Alaska marmot

Several Alaska marmots were sampled in GAAR in 2002 from large colonies inhabiting steep, rocky slopes at Fortress Mountain and Nanushuk River. Our field crew also reported them at Chandler Lake (specimens in the USNM).

There are no confirmed records of this marmot in the other park units of ARCN, however, a study team met hikers in 2001 at Copter Peak, NOAT, who said they saw marmot sign nearby. Also, Dean and Chesemore (1974) reported marmot sign in the northern Baird Mountains near the Nakolik River, and Gardner (1974) sighted a marmot in the vicinity of Mulik Hills on the lower Noatak River.

Spermophilus parryii, arctic ground squirrel

A limited series of arctic ground squirrels was preserved from every park unit in ARCN. The largest series (32) was from BELA on the Seward Peninsula.

A recent molecular study by Eddingsaas et al. (2004) suggest that arctic ground squirrels have a long evolutionary history in Alaska, a history that is intricately linked to

multiple glacial cycles. A highly distinctive split is found between populations north of the Brooks Range in Alaska and arctic Canada and populations further south (including animals from the Seward Peninsula and St. Lawrence Island). This split may be indicative of separate species rather than subspecies. Specimens collected from all of ARCN's park units will be valuable to help clarify this relationship.

Tamiasciurus hudsonicus, red squirrel

Red squirrels were sampled in spruce forest at Kallarichuk River and Onion Portage in KOVA, and at Walker Lake and North Fork Koyukuk River in GAAR. The northern distribution of this species is generally limited to spruce forest along the southern drainages of the Brooks Range (Bee and Hall 1956).

Family Castoridae

Castor canadensis, American beaver

Beavers were not seen or reported by our field crews in BELA, CAKR, KOVA, or NOAT, and no specimens are known from these park units. Neither Gardner (1974) nor Dean and Chesemore (1974) mentioned beavers in either KOVA or NOAT. ADFG (1978), however, stated that beavers had recently colonized the Kobuk River valley, particularly in the lower portion of the drainage, and that they occasionally lived in the upper Koyuk River drainage of the Seward Peninsula. If so, they possibly live in BELA.

Beavers were noted in GAAR at North Fork Koyukuk River, and have been reported from as far north as the Hunt Fork of the John River (Bee and Hall 1956), and Walker Lake in the upper Kobuk River valley (Dean and Chesemore 1974).

Family Muridae

Clethrionomys rutilus, northern red-backed vole

This holarctic vole lives extensively and periodically in abundance throughout most of the state and in a wide variety of habitat types, especially forests. It was the most frequently captured species overall, comprising more than a quarter of all captures in our four field seasons of study (Table 4). A comparison of relative abundance (Figure 6) indicates that in 2000 and 2002 this species was more abundant.

Dicrostonyx groenlandicus, collared lemming

The collared lemming is an inhabitant of the treeless tundra zones of northern, western, and southwestern Alaska, extending into the eastern Aleutian Islands and on St. Lawrence Island in the Bering Sea (Hall 1981).

In four field seasons of study we captured only 11 collared lemmings in ARCN. A single animal from the Waring Mountains in 2003 provided the first verified record of this arctic species for KOVA.

Lemmus trimucronatus, brown lemming

Small numbers of brown lemmings were sampled in each of the five park units of ARCN, with more than half (34) coming from four localities in GAAR in 2002. Most were associated with mesic and wet herbaceous habitats usually in or near forested areas.

Microtus miurus, singing vole

We sampled a total of 101 singing voles from seven localities in BELA, CAKR, and NOAT in 2001. Singing voles were abundant in 2002 (Figure 6) and 466 individuals were sampled from seven of eight localities in GAAR. The largest series was from Agiak Lake. In 2003, 32 singing voles were taken at Kakagrak Hills in CAKR. Samples taken that year from Salmon River (6) and Akillik River (24) constitute the first documented records of this vole for KOVA.

Microtus oeconomus, tundra vole

The tundra vole was the most frequently captured species in 2002 and overall was second in abundance among small mammals.

Tundra voles have an exceptionally broad distribution across Alaska and adjacent northwestern Canada. They also have a vast range across northern Eurasia (Musser and Carleton 1993) and are a relatively recent colonizer of North America (Galbreath and Cook 2004). They are found in a wide variety of open habitats at various elevations (Banfield 1974; Lance and Cook 1998).

Microtus pennsylvanicus, meadow vole

The capture of meadow voles at three localities in 2002 is the first documentation of this widespread interior Alaska species in GAAR and ARCN. The three samples that year from Walker Lake are the first records of this species for the Kobuk River drainage. This indicates that the species eventually may be found in KOVA farther down river.

Microtus xanthognathus, taiga vole

The taiga vole is a semicolonial species of primarily open forest and riparian scrub that we found only at Kallarichuk River and Kavet Creek in KOVA and at Walker Lake in GAAR. These localities are at the extreme northwestern limit of their known range (Conroy and Cook 1999).

Ondatra zibethicus, muskrat

Muskrats are found throughout most of the Alaska mainland south of the Brooks Range (Hall 1981).

A single muskrat was collected in BELA at Devil Mountain Lakes in 2001. This aquatic vole has been documented in CAKR (Kilikmak Creek; UAM) and NOAT (USNM; Gardner 1974). No specimen is known to be specifically from KOVA, although apparently they were abundant in the lower Kobuk River Valley (Dean and Chesemore 1974).

No muskrats were reported in GAAR during this study. This species has, however, been collected in this park from near Anorat Creek, upper Noatak River (UAM; USNM; Gardner 1974), and has been reported in the John River as far upstream as Hunt Fork (Bee and Hall 1956).

Synaptomys borealis, northern bog lemming

Northern bog lemmings were not encountered in any ARCN park unit except GAAR, where we found them at Lake Takahula (15 captures), Walker Lake (27), and North Fork Koyukuk River (34). There is a good chance that this species will eventually be found in KOVA since Swanson (1996; UAM) reported finding it in seral spruce forest in the upper Kobuk River valley. This species is usually uncommon to rare throughout forested Alaska but can become numerous some years.

Family Erethizontidae

Erethizon dorsatum, North American porcupine

Porcupines are apparently rare but widespread throughout ARCN. A single animal was collected at Asik Mountain in NOAT. In GAAR, a porcupine was collected at Nunushuk River and another at Walker Lake, where two others were also seen. Residents of Lake Takahula reported seeing an occasional porcupine. UAM has a porcupine specimen from the Great Kobuk Sand Dunes in KOVA.

Order LAGOMORPHA—Pikas and Hares

Family Leporidae

Lepus americanus, snowshoe hare

The snowshoe hare lives throughout the boreal forests of Alaska. According to the ADFG (1978), during the low points of their population cycles these animals rarely live in tundra areas. In this study, the remains of a foot believed to be from a snowshoe hare were found at Kuzitrin Lake in BELA. Snowshoe hares have been reported in riparian and forest habitats along the Kobuk and Noatak rivers (Henshaw 1966; Dean and Chesemore 1974; Gardner 1974). UAM and USNM have hare specimens that were collected at Arviriaq on the Eli River in the Noatak River drainage.

No hares were collected in GAAR, but their sign was noted at North Fork Koyukuk River. The USNM has hare specimens from the upper John River. Snowshoe hares are localized north of the Brooks Range, being restricted to willows along major water courses (ADFG 1978). Snowshoe hares may have first arrived north of the Brooks Range by colonizing along the Colville River and some of the other major western drainages in the early 1900s (Klein 1995).

Lepus othus, Alaskan hare

The Alaskan hare is currently found in the tundra regions south of Kotzebue Sound (Klein 1995). It has been documented with specimens in BELA on the Seward Peninsula. Historically, its range may have extended farther north. A Kotzebue resident recently reported seeing Alaskan hares in the Noatak River delta area and on the lower Agashashok River (Alex Whiting, pers. comm.), suggesting the possible occurrence of this Alaska endemic in NOAT and perhaps CAKR. This species is closely related to *Lepus arcticus* of the high Canadian Arctic and *Lepus timidus* of Asia (Waltari et al. 2004).

HABITAT AFFINITIES

Habitats of small mammals are often defined by their association with particular plants (Hoffmeister 1986). Under the influences of the topography, soils, climate conditions, and other ecological factors, plants may be organized into distinct groups referred to as vegetative communities, associations, or types. Mammals can often be associated with particular plant communities, some with macrohabitats, most others—especially the smallest mammals—with microhabitats. Some species are restricted to a few communities, while others are found in many. The degree of a species' dominance in a particular vegetation community and its range across various communities often is related to varying population levels.

Populations of small mammals living in high latitudes often fluctuate dramatically from year to year and season to season (see Figure 6). These shifts in abundance, along with dynamic interspecific interaction (particularly among congeneric species) suggest that long-term studies of small mammal communities will be required to carefully assess the particular affinities of each species.

In addition to vegetation, other features and factors may influence a species' distribution, including topography, soil types, snow cover, availability of food, occurrence of pathogens, and the presence of other important features, such as water bodies, rocks, and ground litter. The unique biogeographic and evolutionary history of each species also influences its current distribution. Because Alaska's habitats have changed markedly since the last glaciation, the current distribution of nearly all species must be viewed in the dynamic geologic and climatic histories of these high latitudes.

Our preliminary work indicates that the small mammals species were unevenly distributed. Collared lemmings, barren ground shrews, and arctic ground squirrels were generally restricted to tundra localities in ARCN, whereas taiga voles, meadow voles, bog lemmings, pygmy shrews, and red squirrels were exclusively or predominantly southern and boreal in their distributions.

Patterns of habitat occupancy indicated that northern red-backed voles, overall the most common small mammal in ARCN, were sampled in all major vegetation types, but they were most abundant in forested habitats (Table 5). The local distribution of this common species may be closely tied to the presence of overhead cover, especially woody plant cover. Tall tussocks may serve as overhead protection in non-forested habitats.

The general habitat requirements of shrews are related to invertebrate abundance and physical conditions, such as temperature and moisture (Nagorsen 1996). All shrews seem to require sites with adequate ground cover, regardless of major vegetation type. The small number of tiny shrews (10) we were able to capture in ARCN were restricted to scrub and herbaceous habitats. Of particular interest was the pitfall capture of a single tiny shrew in tussock tundra at Fortress Mountain on the north slope of the Brooks Range.

The four species of *Microtus* we sampled displayed differing patterns of habitat occupancy. Taiga voles were restricted to open forest and riparian scrub habitats, while singing voles lived primarily in mesic-to-dry herbaceous and scrub habitats at higher el-

evations. Tundra voles, in contrast, occupied grassy situations across a relatively broad range of vegetation types and elevations, while meadow voles were generally restricted to lowland wet meadows and riparian habitats in the taiga zone.

Small mammal population levels varied considerably between field seasons and 2002 was a year of abundance for many species (Figure 6).

DISCUSSION AND SIGNIFICANCE

This study confirms the importance of ongoing, multiyear efforts to fully document the region's small mammal fauna. Such persistence has paid a large dividend in ARCN with the discovery of five new species in GAAR, five in KOVA, three in CAKR, and two in BELA (Table 3). Although no new species were added to NOAT's mammal checklist, we suspect that with continued effort several more species will be found there as well (e.g., Alaska marmot, tiny shrew).

Our discovery of the tiny shrew, perhaps the rarest and poorest known mammal in North America, in four of five ARCN park units, namely GAAR, KOVA, CAKR, and BELA, was an unanticipated surprise. These records significantly expand the known range of the species and, together with samples collected elsewhere in Alaska, there are now 37 specimens.

This inventory also confirms that ARCN has a rich assemblage of arctic and subarctic mammals. Of ARCN's 39 species of land mammals, most have holarctic distributions or close affinities with Old World species (e.g., Rausch 1963; Hoffmann and Peterson 1967; Hoffmann, Koeppl, and Nadler 1979). As shown in Table 3, all of the small mammals (and 85% of all land mammals) believed to live in ARCN are now documented with at least a few specimens for each animal. Specimen coverage in ARCN individual park units, however, varies from 79% (KOVA) to 100% (GAAR).

Patterns of general habitat occupancy among 24 species sampled in ARCN were comparable to those reported in other studies of Alaska small mammal communities (e.g., Bee and Hall 1956; Mayo 1963; Pruitt 1966, 1968; Childs 1969; Dean and Chesemore 1974; Gardner 1974; Wolff and Lidicker 1980; Douglass 1984; Batzli and Henttonen 1993; Swanson 1996). Five species—two insectivores (cinereus shrew, montane shrew), a generalized fruit, seed, and leaf feeder (northern red-backed vole), and two graminoid grazers (tundra vole, singing vole)—dominated the small mammal community of ARCN, accounting for more than 83% of all trapline captures.

The most significant and valuable product of this inventory is the large collection of scientific specimens that are documented well and diversely prepared.

Why specimens? As elucidated by Reynolds et al. (1996), voucher specimens and corresponding data assembled during field surveys are critical for accurate identification of the animals studied and for verification of data gathered during the investigation. Voucher specimens are particularly valuable for studies of the smaller species that are difficult to identify (e.g., shrews, *Microtus* voles) and often poorly known (most Alaska small mammals).

Long after the original inventory is completed, voucher specimens and their associated materials will be used for a wide array of purposes, such as taxonomic revisions, biogeographic and conservation studies (e.g., Cook and MacDonald 2001), and studies of evolution (Cook et al. 2001), parasitology (e.g., Hoberg et al. 2003), and epidemiology (Yates et al. 2002).

Voucher specimens also provide a critical historical baseline for assessment of change caused by natural or human disturbances. Because large series of specimens represent historical populations, their value increases over time, particularly as the diversity of many localities is degraded. Solid inventories of federal lands have become increasingly important. These lands are now often used to establish baseline conditions for investigations aimed at documenting human influences and other impacts responsible for environmental change. Lessons learned from the Exxon Valdez disaster in Prince William Sound suggest that baseline data are critical for interpreting the results of these impacts. NPS has an opportunity to incorporate annual sampling and archiving of select small mammals into their monitoring initiative. Such collections would be valuable to monitor change over time in a major biotic component of the Alaska's parklands. If these samples are not regularly archived, NPS will miss a tremendous opportunity to establish significant baseline data for future analyses of environmental change.

With PCR (polymerase chain reaction) and other innovations in the study of DNA, we now can examine and monitor genetic variation in populations of animals that were collected during different times. This provides a more rigorous view of temporal genetic variation and population structure. For example, known contact zones between taxa can now be reanalyzed for temporal stability (but only if specimens from the contact zone were collected at regular intervals). Because of the dynamic geologic history of Alaska, including the role that glaciers have played in the distribution of organisms, these kinds of studies are essential to documenting and managing biodiversity. Recent concern with persistent organic pollutants (POPS) combined with our increasing ability to track them, creates another use for these specimens in monitoring environmental quality and other related studies.

Without the preservation of specimens, inventories such as this one would have extremely limited value. Federal tax dollars used for biodiversity assessments are most efficiently spent if agencies recognize the critical need for vouchers and provide support in both field and museum budgets for their preservation and maintenance (Reynolds et al. 1996).

While the importance of museum specimens should be generally recognized and their preparation considered essential to good science, for many the question remains: Why collect so many specimens? Below are some perspectives on Alaska and the need for cooperative efforts that help answer this question:

- Alaska mammalogy is still in the early exploration phase and several new species have been discovered in the state in the last 15 years (Dokuchaev 1997; MacDonald and Cook 1996). For most species of Alaska mammals, many areas, including ARCN, are poorly known and inadequately represented in systematic collections. This point is acutely apparent when recent phylogeographic studies are reviewed (e.g., Fleming and Cook 2002; Stone, Flynn, and Cook 2002; Fedorov et al. 2003; Cook et al. 2001). In some cases, cryptic species have been identified (Small, Stone, and Cook 2003).
- Small numbers of specimens will not adequately represent the inherent morphologic, genetic, and parasitic variation that exists in and among populations. Rigorous and statistically defensible scientific studies require large samples of well-preserved and

diverse specimens to account for variations in age, sex, and geographic distribution, as well as among individuals. Taxonomic studies based on skull morphology may require undamaged material from 20 or more adult individuals of each sex per locality (i.e., a minimum of 40 adult individuals per population).

- Many of the shrews and small rodents are difficult or impossible to identify except through the careful study of specimens. Close examination of tooth pattern and comparison of body measurements and other characteristics are necessary to distinguish most of Alaska's shrews. Voles of the genus *Microtus* can also be especially difficult to differentiate.
- Considerable sampling effort is needed to document rare and uncommon species. In this survey, thousands of trap-nights were required to secure 10 tiny shrews and 11 colored lemmings.
- The number of animals removed from a population only has biological significance if it is related to the total number of animals in the population and their rate of replacement (Reynolds et al. 1996). Because Alaska's small mammals are short-lived and prolific, their reproductive potential is more than sufficient to accommodate low levels of removal through the sampling methods used in these inventory projects.
- Because federal resource agencies are mandated to efficiently and effectively manage and monitor the lands and wildlife entrusted to them, there must be solid documentation and a clear understanding of the distribution and status of biodiversity. One of the most efficient means to achieve this goal is to build a solid archive of material that represents temporal and spatial slices of these environments (Cook et al. 2004). Natural history collections are such a resource. These collections can be enhanced in a variety of ways. For example, large numbers of furbearers and game mammals are harvested each year in or near parklands in Alaska. With very little cost, the carcasses or tissue samples could be archived annually from a significant number of individuals. Such a resource would provide an invaluable means of assessing and monitoring the health of these populations and their environments through time. NPS should set up a collaborative program with the ADFG and a natural history museum to build this resource.

RECOMMENDATIONS FOR FUTURE INVENTORY AND MONITORING EFFORTS

- i. Inventory studies must be viewed as an ongoing process and NPS must remain committed to continuing the efforts begun in these initial inventories. Future monitoring efforts should include a sampling regime that regularly vouchers diverse specimen preparations of representative species. These initial inventories have set the stage for additional collaborative efforts to fully document the mammal fauna of ARCN.
 - The discovery of the tiny shrew, *Sorex yukonicus*, in ARCN and other NPS Networks across the state, demonstrates just how much we have yet to learn about Alaska's small mammal fauna. Additional pitfall trapping in ARCN (NOAT in particular) and elsewhere in the state is needed to help determine the full geographic distribution and ecological requirements of this rare species, and to provide an adequate database of specimens to more precisely assess the shrew's taxonomic relationship with other Beringian shrews. Its discovery further illustrates the value of a specimen-based approach to inventory studies. The initial detection of this species new to science was made possible only because large series of shrew specimens sampled in surveys from the 1980s were preserved and available for later study by specialists.
 - Marmots, presumably *Marmota broweri*, have been reported from both the De Long and Baird mountains. The status and distribution of this Alaska endemic is poorly understood and in need of additional documentation (only about 40 specimens exist in collections). Recent genetic work supported the distinctiveness of *M. broweri* from both *M. camtschatica* of eastern Siberia and *M. caligata* of the Nearctic (Steppan et al. 1999).
 - The status and distribution of Alaskan hares, *Lepus othus*, particularly in NOAT, CAKR and KOVA, needs clarification and documentation.
 - Vouchers are lacking for a number of other small mammal species that probably live in various ARCN units, including ermine (BELA, CAKR, KOVA), least weasel (CAKR, KOVA), Alaska marmot (NOAT, perhaps KOVA), muskrat (KOVA), porcupine (BELA, CAKR), and snowshoe hare (KOVA, perhaps BELA and CAKR).
 - Ongoing efforts could expand the geographic range of several interior Alaska taiga species, including pygmy shrew, northern bog lemming, meadow vole, and possibly northern flying squirrel (*Glaucomys sabrinus*).
2. The small mammals of ARCN offer a unique opportunity for an array of studies that relate the dynamic glacial history of the region to the evolution and geography of its biota. The systematic relationships among Beringian shrews have been particularly problematic and are in need of further research efforts that are based on adequate series of diverse and well-preserved specimens. Considerable interest in the effects of climate change on biotic diversity suggests that studies of the fauna and flora of ARCN could be key to understanding these impacts. Furthermore, planned expansion of

industrialization of the North Slope in the National Petroleum Reserve-Alaska and the Arctic National Wildlife Refuge indicate that these specimens may become essential to documenting baseline levels of pollutants (POPS).

3. A study on the phylogeography of the arctic ground squirrel (Eddingsaas et al. 2004) has identified a highly divergent clade (new species) of *Spermophilus parryii* in arctic Alaska that is distinct from populations on the Seward Peninsula and other areas. This finding suggests the probable occurrence of two separate species of ground squirrel inhabiting ARCN. The finding also points out the rudimentary nature of our understanding and illustrates the importance of specimen-based approaches to ongoing studies in which the Inventory and Monitoring Program of NPS plays a vital role.
4. Ongoing efforts could expand our knowledge of the distributions and habitat preferences of arctic and boreal species that come in contact in ARCN. They could also provide important baseline information for monitoring distribution shifts in relation to climate changes. However, efforts to provide fine-grained geographic analyses of quantifiable precision will largely be a waste of time and energy unless enough commitment is made to a long term (multidecade) investigation. We feel such an effort is unwarranted given other more pressing issues related to wildlife.
5. Long-term monitoring on biotic change is best accomplished by preserving materials from populations sampled periodically over time. Such efforts could be enhanced significantly if a number of trapline transects were sampled in each of Alaska's far-flung national parks (and wildlife refuges) for a three- or four-day period each summer using several trap types, particularly pitfall traps. Such an effort, perhaps done opportunistically by park personnel, would provide a cost-effective and time-sensitive series of valuable specimens from a larger number of species. The effort would also help elucidate variation in abundance at broader geographic scales, as suggested in our trapping efforts in ARCN and elsewhere in 2002 (Figure 7). Specimen-based monitoring of northern small mammal populations has been ongoing in Scandinavia for many decades. We encourage NPS to develop a similar monitoring program throughout Alaska's national park system.

ACKNOWLEDGMENTS

This project involved the hard work and diverse talents of many. We appreciate the enthusiastic help and support of Terri Ball, John Burch, Melanie Cook, Lois Dalle-Molle, Tom Heinlein, Jefferson Jacobs, Spring Pengilly, Jerry Post, Brad Shults, Shelli Swanson, Sara Wesser and others of NPS for this continued effort.

Our thanks to Amy Runck, in particular, and the other field crew members: Robert Allen, John Bender II, Nikolai Dokuchaev, Vadim Fedorov, Alexei Fedorov, Kerynn Fisher, Robert Foster, Heikki Henttonen, Kyndall Hildebrandt, Brandy Jacobsen, Juha Laakkonen, Dusty L. McDonald, Jukka Niemimaa, Elena Potikha, Richard Runck, Skylar Smith, Eric Tomasik, Karl Vanderwood, Brent Wagner, and Eric Waltari. We also thank Brandy Jacobsen, Gordon Jarrell, Dusty MacDonald, and Link Olson of UAM's Mammal Collection.

FIGURES

Figure 1. General sampling localities in Gates of the Arctic National Park & Preserve: (1) Lake Tulilik, (2) Lake Isiak, (3) Takahula Lake, (4) Walker Lake, (5) Agiak Lake, (6) North Fork Koyukuk River, (7) Fortress Mountain, and (8) Nanushuk River. Locality details are outlined in Field Locations (page 3).

Figure 2. General sampling localities in Cape Krusenstern National Monument: (1-2) Red Dog Road, (3) Rabbit Creek, (4) Kakagrak Hills, (5) Situkuyok River, (6) Igisukruk Mountain, and (7) Tukrok River; Kobuk Valley National Park: (1) Baird Mountains, Salmon River, (2) headwaters Akillik River, (3) Onion Portage, (4) Waring Mountains, (5) Kavet Creek, and (6) Kallarichuk River; Noatak National Preserve: (1) Asik Mountain, (2) Kelly River, (3) Copter Peak, (4) Aniralik Lake, (5) Desperation Lake, (6) Sidik Lake, and (7) Kaluich Creek. Locality details are outlined in Field Locations (page 3).

Figure 3. General sampling localities in Bering Land Bridge National Preserve: (1) Devil Mountain Lakes, (2) Kuzitrin Lake, and (3) Serpentine Hot Springs. Locality details are outlined in Field Locations (page 3).

Figure 4. *Proportion (%) of small mammal relative abundance (captures/100 trap nights) in three major vegetation types, Arctic Network, NPS Alaska, 2000–03.*

Figure 5. *Range of occurrence of mammal species across 12 of Alaska's national park units (Southeast Network excluded). For example, cinereus shrew and red-backed vole are broadly distributed, occurring in all park units, while long-tailed vole has a relatively narrow distribution, occurring in only 2 of 12 park units.*

Figure 6. Fluctuation in the relative abundances (captures/100 trap nights) of select small mammals in the NPS Arctic Network, Alaska, from field seasons 2000 through 2003.

Figure 7. Relative abundance of small mammals sampled on trapline transects in eight major watersheds in Alaska, July–August 2002.

APPENDIX 1. SPECIMENS COLLECTED

- Table Ara: Bering Land Bridge National Preserve (page 55)
- Table Arb: Cape Krusenstern National Monument (page 72)
- Table Arc: Gates of the Arctic National Park and Preserve (page 86)
- Table Aid: Kobuk Valley National Park (page 157)
- Table Aie: Noatak National Preserve (page 173)

Table Aia. Mammal specimens in the University of Alaska Museum (UAM) from BCP/NPS inventories of the **Bering Land Bridge National Preserve**, Alaska, field seasons 2000–2003.

- Key to the Shrews of Alaska (page 201)
- Key to the Small Rodents of Alaska (page 202)

A Note on Specimen Preparation

Time is saved (and confusion avoided) if you decide how each specimen is to be prepared before you begin to work up the specimens. Decide which animals will be examined for endoparasites, preserved as alcoholics, made into skin and skeleton, sampled for Telford, etc.

Notes on Ethanol Preservation

To produce the best alcoholic specimen, captures need to be placed into ethanol as soon as possible. Because the goal of this preservation method is to preserve soft tissues, which decompose quickly, preparing specimens slated for alcohol at the end of the evening results in poor quality specimens.

We have found that the best way to “cure” alcoholics is to place the captures in a bucket or jar containing highly concentrated ethanol (80-95%). About 2 days after the specimens are placed into the curing container they will become stiff, at this point they should be transferred into a more dilute concentration of ethanol (about 70%).

It is important to check the specimens while they are in the concentrated ethanol. If they are not becoming stiff they may be in danger of decomposing and molding. Do not over-fill the curing containers with specimens. The curing container should be no more than 2/3 full with specimens. .

1. Do not use markers or regular ink pens on skull tags (they are soluble in ethanol). Use a permanent pen (Uniball Deluxe-preferred) or pencil to write the AF number on the specimen's tag.
2. Measure and weigh specimens before cutting the abdominal cavity.

3. Make the incision in the body as small as possible (but large enough so that you can examine the reproductive organs). The incision should be from above the pelvis to the rib cage (not cutting through the ribs). Not only does this incision allow you to sex the specimen, but it enables the ethanol to enter the body cavity more quickly, resulting in a better preservation of the specimen.
4. Place a little piece of cotton into the body cavity to help keep the organs inside of the body.
5. Tie specimen tag onto the right hind foot. Use a square knot and make sure the tag is secure.
6. Place the specimens into a container with 80-95% ethanol ("curing" container). Mix the ethanol and specimens around in the container. After a couple of days the specimen should be stiff. At this time remove the specimen and place in a container with 70% ethanol. Do not keep adding fresh captures to the curing container without adding additional concentrated ethanol for after time the ethanol will become too dilute. Subsequent specimens will not be preserved very well and fur will start to slip off the carcass and tissues will be of lesser quality. Diluted ethanol from the curing container can be put into the holding container as more specimens are added.
7. Ethanol preservation is not for "poor quality" specimens. Because we are preserving soft tissue a rotting specimen makes a very lousy "alcoholic."

Notes on Making Carcasses

1. Bloody specimen tags are problematic! Not only may their AF numbers be difficult to decipher, but the dermestid beetles will eat the tags, making it impossible to correctly identify the carcass. Please be sure to keep specimen tags as clean as possible. When drying the carcass keep the tag off of the body.
2. Try to keep carcasses from touching each other while they are drying. Upon their separation, legs or other body parts may break off from their owner and be associated with the wrong animal.
3. Remove eyeballs and tongue from all skulls. Remove brain from animals larger than a vole.
4. Tie legs and feet to skull in the appropriate manner.
5. Carcasses need to dry and be fly-free. Weather may hinder the drying process and the carcasses may become slightly moldy. To help dry the carcasses, hang them up in the prep tent during prepping sessions. Heat generated from propane lamps may aid in drying of the carcasses.
6. Keep flies and maggots off of the carcasses. Remove any maggots from the carcasses. Carcasses that are overcome with maggot infestations can be placed in ethanol. This will kill the maggots. Try to avoid maggot infestations!
7. Carcasses are potential bear snacks and they need to be stored out bear access at night and when away from camp. Placing carcasses in a box suspended from a tree works well. In addition, you may need to place them in the bear-proof container.

8. Attach an accession label to the carcass wire ring so that they will be easily sorted and processed at the museum.

How to Fill Out an AF (NK) Sheet

The AF sheet is the key that links all the preparations and preserved materials from an individual animal together. Without a properly completed AF sheet, a sample may have no value. Therefore we urge you to read and understand the following protocols.

“AF sheets” are prenumbered catalog pages for the Alaska Frozen Tissue Collection. One AF number, and therefore one AF sheet, is assigned to each individual animal collected irrespective of the number of tubes of tissue that are preserved.

If embryos are sampled, or frozen whole in the tubes, they are considered separate individuals and given separate AF numbers. Their relationship to maternal samples should be noted. Generally these will not have a voucher apart from the mother.

Data from AF sheets are entered into the Mammal Collection database as soon as possible when specimens are received. We wish to facilitate access to the tissues and basic specimen data even while the rest of the specimen is still being processed but for this system to function, AF sheets must have reasonably complete information.

Pens: Ink should be black and of archival quality. We recommend using a Uniball Deluxe pen with black ink for AF sheets. An ultra-fine-point permanent Nalgene lab marker no 6310-0010, or ultra-fine-point Sharpie are used for writing on nunc tubes. Pencil is preferable to water soluble ink on AF sheets. Do not use sharpies on AF pages (it bleeds through).

Collector: The name of the person (or project) who acquired the specimen and their affiliation, if significant. For example: Lester Newcomb, USF&WS; wolf control, ADF&G; John S. Chythlook.

Preparator: The name of the person who prepared the specimen, preferably the one who filled out the AF sheet. It would be helpful to include all of the person’s initials if these are used as part of the preparator’s number (below). This can be left blank if preparator and collector are the same person.

Field number #: This is the number that is used to associate different parts of the specimen, their associated materials, and data sheets. In lieu of personal collecting numbers, AF numbers can be used as the field number.

Species: Ideally this should be the scientific name of the animal, but please put in something. It is not essential that the identity be certain; we will identify the voucher specimen when it is catalogued.

Valid examples: *Myotis lucifugus* *Clethrionomys* sp.

Sex: Self-explanatory.

Country/State: Self-explanatory. Valid examples: USA/Alaska Russia/Magadanskaya oblast Canada/Quebec

Quad: (for Alaskan specimens) U.S. Geological Survey 1:250,000 quadrangle name. Leave blank if unknown or if specimens were collected outside of Alaska. We can work it out if other geographic data are complete. See “latitude and longitude” for more on this.

District: Record islands, national parks, counties (for the contiguous United States), and game management units in this field.

Specific locality: The most precise description of the locality where the specimen was collected. This description should refer to permanent landmarks that are named on standard maps or in gazetteers. Consider whether or not your description of a locality will be clear fifty years from now to someone who has never been in the region. Roads, campgrounds, and cabins are ephemeral; cities, mountains, and rivers are more dependable.

Latitude & Longitude: We need geographic coordinates to relate specimen data to geographic databases. Coordinates are best determined by the collector, or someone with first-hand knowledge of the locality. The format in our database is degrees-minutes-seconds. If your data are more precise than the nearest minute, please make sure that your units are clearly labeled as seconds, decimal fractions of minutes, or whatever applies. The hemisphere is not necessarily obvious, especially in Chukotka or the western Aleutians. Please be sure to label longitudes with E(ast) or W(est) and latitudes with N(orth) or S(outh).

Authority: From where the latitude and longitude data were collected, such as a GPS, GNIS=Geographic Names Information System (United States), Orth = Daniel Orth’s Dictionary of Alaska Place Names, 1:250,000 maps (accuracy to within one minute is adequate).

Date of death: The day that the specimen was collected or the date that it died, if these are not the same. Don’t hesitate to elaborate if the situation is more complicated, for instance, when a stranded marine mammal is located, but the date of death is unknown. Dates should be in the format Day/Month/Year, with the month spelled out, for example 21 January 2000.

Date of preparation: The date that the tissues were removed from the animal. If this is left blank, we assume that it is the same as the date of death. Remember, day/month/year per the example 21 January 2000.

Nature of voucher: Indicate what, if anything, is being submitted as a voucher for the tissues. For mammals, we encourage a skull or skeleton for a voucher. We assume that a skull is included if “skeleton” is circled. For example, if you were submitting tissues from a vole, which had vouchered skin and skeleton, you would circle “skin” and “skeleton.”

Nature of voucher (Circle one or more): skin skull skeleton fluid-preserved
whole frozen tissues only other

If no voucher is being submitted with the tissue, circle “tissues only.” If the specimen is a whole frozen embryo, in a cryotube, circle “whole frozen.”

Preserved material: Indicate the number of tubes of each tissue that were preserved. If heart and kidney were frozen together in one tube, write “1” under #tubes for “heart & kidney” and “Fz” for frozen, under pres.

Preserved	#tube	pres	Preserved	#tube	pres
heart			blood		
kidney			karyotype		
heart & kidney			ecto parasites		
H, lung, spleen	1	Fz	nematode		
Liver & kidney			cestode		
spleen			coccidia		
lung			other()		
muscle			other()		

Heart and kidney should only be frozen together if there is not enough of either one to fill cryotube. If the specimen is an embryo, write “embryo” in the blank for “other.”

Pres: Indicate method used to preserve tissues. Abbreviations such as Fz (frozen), Form (formalin), EtOH (70% ethanol), can be used.

Parasites: Collected parasites should be labeled with the host’s AF number. On the AF sheet, please indicate the type of parasite and the method of preservation.

Other: Please list associated materials that were saved. This might include stomach samples, feces, ear clippings, etc.

Condition of tissues: We ask that you grade the tissues on a scale of one to five for freshness. We realize that this determination is subjective.

Condition of tissues (circle one): (poor) 1 2 3 4 5 (excellent)

- 5 The best tissues. These were taken from a freshly killed animal and put into liquid nitrogen. The animal should not have been dead for more than thirty minutes. Such tissues would presumably be useful for virtually any kind of biochemical analysis.
- 4 These are tissues taken from animals only a few hours postmortem at cool temperatures. Such tissues should not have been previously frozen and thawed.
- 3 These are tissues taken from an animal that has been dead less than sixteen hours at cool temperatures, or tissues taken from an animal that was hard frozen soon after death and then thawed for preparation. Fur is not slipping.
- 2 These tissues may be beginning to show signs of decomposition.
- 1 These tissues are flaccid and thoroughly autolyzed. They probably stink.

Relationship: This field relates biological individuals.

An embryo is related to its mother:

Relationship: embryo of# AF 32145

A mother is related to its embryos:

Relationship: mother of# AF 32146

Repro condition: Record reproductive condition of the specimen; size of testes, number and size of embryos, condition of mammary tissues, etc.

Measurements: Record standard biological measurements. Lengths are recorded in mm, and weight in grams. Any deviation from these units should be indicated after the recorded measurement. Standard measurements for mammals are:

Total length: (with mammals on its back) Measure specimen from tip of nose to tip of fleshy part of tail.

Tail length: (mammal on stomach) Bend tail at a right angle, measure from the bend on the back to tip of the fleshy part of tail.

Hind foot length: (from bottom of the foot) Measure from heel to the end of the longest toe (include toenail).

Height of ear from notch: Measure from notch at bottom of ear to outer edge of ear

Remarks: Feel free to expand on the information given elsewhere, or to add information about the specimen that might be relevant. The back of each AF page should be used for additional information.

How to Fill and Label Cryotubes

In the Alaska Frozen Tissue Collection, tissue samples are stored in 1.8 milliliter plastic cryotubes. These should be labeled with an ultra-fine Nalgene lab marker no. 6310-0010 or a ultra fine “Sharpie” permanent marker prior to cooling. If the tubes are not labeled before cooling, it will be necessary to rewarm the tubes in order to write on them.

The standard tissues saved on birds and mammals are heart, kidney, liver, and spleen. For small species entire organs are often stored in one tube. For larger animals, only a subsample of the organ will fit in a tube. In some cases, muscle, skin, or blood may be the only tissues collected.

Specimens should be kept clean, but are not expected to be sterile. It is especially necessary to avoid cross contamination between individuals. Tiny amounts of DNA from another specimen can be amplified and corrupt results. Therefore, instruments and work surfaces should be cleaned after each individual is sampled. We use a ten percent solution of chlorine bleach in water to clean off instruments. The instruments are wiped dry, then rinsed in clean water, and then wiped until dry with clean tissue paper. Bleach destroys DNA and is an excellent disinfectant. Alcohol preserves DNA and therefore should not be used to clean instruments.

Tube Cape Colors:

Red = Heart, Kidney, Spleen, and Lung, together in one tube -to ISU.

Orange = Kidney (by itself, not with heart) *Yellow* = Liver- To UAM

Gray = Spleen *Lavender* = Brain

White = Whole frozen Embryo or Parasites

Common Problems:

Over filling: Tubes that contain too much tissue will split when the tissue freezes and expands. Observe the fill line (approximately 2/3 full) when preparing large samples.

Loose caps: Caps may come loose and the samples may come out of the tubes. Please tighten caps firmly. This is particularly important when tubes are traveling in Dewar flasks of liquid nitrogen,

Inadequate labeling: Sloppy handwriting and faulty writing implements are major problems. Write the AF number on the tube at least twice, and on the cap once. Don't try to write on greasy, wet, or frozen tubes. Writing may be worn off of tubes if they are subjected to a lot of agitation while traveling in liquid nitrogen. This problem occurs with bags used to presample the tissues as well. Bags should be clearly labeled and if possible, a label should be included in the bag with the sample. Be sure to avoid cross contamination among bagged tissues and try to collect samples large enough so that we can obtain a cleanly trimmed final sample.

How to Preserve Samples in Ethanol for DNA Analysis

While not as useful as fresh frozen tissues, samples for DNA analysis can be preserved in ethyl alcohol (in a pinch, even everclear or vodka works satisfactorily):

1. Take about 0.3 grams of tissue (about the size of a pea). Nick it several times with small scissors or a sharp knife to increase the rate of alcohol penetration. It is not necessary or desirable to cut it into smaller pieces.
2. Place the sample in a cryotube and fill the tube to the fill line with 95% ethanol. Cap the tube tightly and agitate enough to be certain the sample is floating free in the tube.
3. Several hours later (overnight) drain off the alcohol and replace it with fresh. This is done because the water in the tissue has diluted the alcohol. This is especially important if using vodka or other alcohols that are initially less than 95%. Cap the cryotube tightly because the ethanol is quite volatile.

Be extremely careful when labeling the tubes if you use a Sharpie marking pen. Alcohol will dissolve this ink. If possible, place samples from an individual into a separate container with an alcohol-proof label (pencil or Uniball Deluxe pen on waterproof paper works well) or attach such a label to the vial. If you are storing the vials in a cryobox it is also possible to make a map of the locations of individual tubes in the box. Just make sure that they do not get rearranged. Wrapping a rubber band around the box helps prevent disastrous accidental box openings.

How To Preserve Frozen Tissue Samples

Archive Frozen Tissue Samples

Voles, Shrews, and Bats:

- 1 tube of *heart, lungs, spleen, kidneys* (RED caplet) for MSB.
- 1 tube of *liver* (YELLOW caplet) for UAM.

Squirrels, Marmots, Pikas, Hares, and Weasels:

- 1 tube *heart* (RED caplet) for MSB
- 1 tube *liver* (YELLOW caplet) for UAM
- Additional tubes can be taken, i.e., *kidneys* (ORANGE caplet) and *spleen* (GRAY caplet) on any rare captures (like marmots).

Embryos:

- *Embryos are assigned an unique number, not the number of their mother.*
- 1 tube per litter of embryos is preferred (WHITE caplet).
- Use additional tubes (with the same NK number) as needed if all of the embryos can not fit into one tube.
- Use only one NK number per batch of embryos.

Tissues are to be sampled for the frozen tissue collection from about 30 specimens of a given species from any one locality. If more are collected, specimens are to be preserved as alcoholic (or alcoholic and skulls) with their organs left in the carcass. Use your judgement on this. If you collect more than 30 of one species from one locality and feel that there is a reason to freeze tissues from additional specimens (diseased tissues, rare species, contact zone between species, unusual morphology, etc.) then do so.

Other Frozen Samples

Hanta samples from rodents

- Place lungs into the tube last so that they are easily accessible for sub-sampling
- If lungs are too big to be included with H,K, and Spl then use an additional tube for the lungs and write "lung" on the tube (**no caplet**).

Brain from marmots:

- Collect some brain tissue from marmots (LAVENDER caplet).

Endoparasites:

- Frozen endoparasites (nematodes) WHITE caplets.

How to Necropsy

Stomach: Open in a dish of water, examine for nematodes. These are usually associated with the lining of the stomach and are on the outside of the stomach contents.

Lungs: First remove the left half of the lungs for hanta virus (see later) and freeze: be careful and use sterilized forceps only (70% ethanol and cigarette lighter). Label nunc "Hanta." Visually examine rest of lungs for nematodes. These may appear as small tan lesions on the surface and extending deeper into the lung tissue. If nematodes are present freeze ¼ lung in nunc tube (white caplet) and label Lung/Nematode. One rare genus, *Angiostrongylus*, can be found in the big arteries of lungs.

Bladder: Open bladder in petri dish and examine contents under dissecting microscope.

Other Organs/Tissues: Basically parasites can occur in almost any organ- generally they are most abundant in the GI tract, but other organs including the liver (and gall bladder), etc., and the body cavity, should be examined (see Gardner protocols). Liver cysts or other Taeniid larvae loose in the coelom or thoracic cavity should be preserved in 70% ethanol.

Important: Remember that all dishes, and dissecting instruments have to be completely clean and dry between animals. Wash and then rinse with ethanol. Tips of probes, scissors and micro-forceps can also be passed briefly through a flame after dipping in ethanol.

Parasite Handling and Preservation

Cestodes (All mammalian taxa excluding shrews): Following collection from the small intestine, each specimen should be held in filtered water for an extended period (minimum 2 hours, preferably more). This allows the tapeworm to fully relax, which is necessary to examine the internal structure of the proglottids. *Following relaxation and death in water, all strobilate adult tapeworms will be preserved in 70% ethanol.* Preservation should be done flat for large tapes including *Andrya* and some *Hymenolepis* in rodents; this is done by leaving the cestodes in a dish of ethanol overnight, and transferring the specimen to a vial the following day. Use the appropriate size vial for the specimen so there is sufficient preservative (a ratio of about 5:1 in volume for preservative relative to the specimen is maintained). The preservative should be changed once after 24 hours. Some tapeworms in *Microtus* are quite large (up to 20 cm). so be certain to use the proper size vial- one that is large enough for the worm and a sufficient amount of ethanol. Note the location of cestode in the intestine and record in the NK book. If problems with vial size, a big tape can cut in two parts and preserved in two vials. Use one number with a and b, mark on the notes.

Digenia (Flukes): Flukes can be relaxed in filtered water, which often allows specimens to expel eggs that might otherwise obscure some organs. Preserve flukes in 70% ethanol (or alternatively, freeze in LN₂ (white caplet)); if there are large numbers do both. Keep parasites from different organ systems separate.

Nematodes: Nematodes should not be held in water for extended periods of time, as Osmotic pressure will eventually cause the specimen to burst. Specimens should be washed in water or saline and then preserved in 70% ethanol or frozen in LN₂ (white caplet) if there are large numbers do both. Keep parasites from different organ systems separate.

Enteric Coccidians: Fecal samples to isolate coccidia should be taken from select species of mammals. Collect a few pellets from the rectum or a scraping from the caecum/large intestine, crush the pellets and put in potassium dichromate (20/0 solution). **Important:** 1) Do not overfill the vial, oxygen is necessary for survival of the coccidia, and 2) the specimens should not be frozen.

Brain tissue, Marmota: Collect some brain tissue for freezing (LAVENDER caplet).

Protocols for Ectoparasites: Examine pelage for ticks, fleas and mites. Wash collection bag with 70% ethanol, then cut corner of bag and let contents drain into a small vial. Add ecto juice to fill. Comment in the NK book the condition of the animal (as to whether or not the animal was wet vs. dry). **Do not reuse collection bags!!**

Protocols for Hanta Virus: Focus on the following rodents: *Clethrionomys*, *Lemmus*, *Dicrostonyx* and *Microtus*. Be sterile. The rodent's left lobes of lungs are frozen in a single tube do not include with other organs; mark tube as Hanta use no caplet (these will go with Henttonen for later screening).

Protocols for Schistosomes: (E.S. Loker) Examine closely the mesenteric veins for any unusual trematode-like forms.

Tissue- Cyst Forming Coccidia: Typically these will be found in old arvicolines. *Sarcocystis* may be present on the peritoneum and in the musculature of the hind legs as whitish thread-like structures; if observed in the peritoneum, preserve some hind-leg musculature in 70% ethanol. *Frenkelia* may be present in the brain; cysts are easily seen as whitish spots (0.5-1.0 mm) on the surface of the brain. Do not collect from specimens with intact skulls destined for the Museum. In animals with broken skulls: first remove the upper part of the skull by cutting the bone between the eyes; remove skin from the eyes backwards; cut the skull (but not the brain) starting from the eyes along the sides, and then lift the top from the anterior part exposing the brain. If present, cysts (whitish spots) will be visible; remove brain with forceps; slice into 2 or 3 parts; preserve in 70% ethanol. Remember to save the dentition from these animals.

KEY TO ORDERS OF ALASKA SMALL MAMMALS

- Body very small, snout relatively long and slender pointed, eyes tiny, 5 clawed toes on forefeet; needle-sharp teeth in a continuous row; zygomatic arches and auditory bulla absent SHREWS (INSECTIVORA)
- Body larger, snout blunter, 4 clawed toes on forefeet; 2 pairs of large, curved, chisel-like incisor teeth visible in front of the mouth with a large space (diastema) between incisors and the row of cheek-teeth; zygomatic arches and auditory bulla present RODENTS (RODENTIA)

KEY TO THE SHREWS OF ALASKA

1. • Only 3 unicuspid teeth clearly visible when viewed from the side (3rd and 5th unicuspids tiny).....*Sorex hoyi*
 - 4-5 unicuspid teeth visible when viewed from the side ↓ 2
2. • 3rd unicuspid tooth noticeably smaller than the 4th ↓ 3
 - 3rd unicuspid tooth equal to or larger than the 4th ↓ 4
3. • Total length usually greater than 130 mm; Skull length usually greater than 19 mm; pelage gray-black; fringe of stiff hairs on hind feet *Sorex palustris*
 - Total length less than 130 mm; Skull length less than 19 mm; pelage brownish; hind feet without fringe of stiff hairs *Sorex monticolus*
4. • Post-mandibular canal on the jaw well developed; 3rd unicuspid tooth noticeably larger than 4th; 5th clearly visible and pigmented ↓ 5
 - Post-mandibular canal absent; 3rd unicuspid tooth equal or nearly equal to 4th; 5th inconspicuous and unpigmented ↓ 6
5. • Body tiny (usually less than 80 mm, tail less than 28 mm, hind foot less than 10 mm); 1st unicuspid noticeably larger than 2nd; 2nd about equal to 3rd; pelage indistinctly tricolored without sharply contrasting dorsal stripe *Sorex yukonicus*
 - Body much larger (usually greater than 90 mm, tail greater than 30 mm, hind foot greater than 12); 1st unicuspid smaller than 2nd; 2nd noticeably larger than 3rd; pelage distinctly tricolored with sharply contrasting dorsal stripe *Sorex tundrensis*
6. • Found only on islands in the Bering Sea ↓ 7
 - Not as above ↓ 8
7. • Known only from St. Paul, Pribilof Islands*Sorex hydrodromus*
 - Known only from St. Lawrence Island *Sorex jacksoni*
8. • Skull length usually less than 15 mm; tail short (usually less than 30 mm), light (pale brown above, whitish below), with a blackish terminal tuft; pelage tricolored with light color of underparts extending far up the sides, with brown back forming a well-defined dorsal stripe *Sorex ugyunak*

- Skull length usually greater than 15 mm; tail longer (usually greater than 30 mm), darker, and lacking a dark terminal tuft; pelage usually bicolored lacking a distinct dorsal stripe *Sorex cinereus*

KEY TO THE SMALL RODENTS OF ALASKA

- I. • Hind legs considerably longer than frontlegs; tail very long in relation to body size, usually greater than 125 mm; infraorbital canal of skull large and oval; 4 upper cheek-teeth that includes a small premolar (DIPODIDAE) ↓ 2
 - Front legs and hind legs equal in size; tail length variable relative to total size; infraorbital canal smaller, being much wider at the top than at the bottom; 3 upper cheek-teeth (MURIDAE) ↓ 3
2. • Length of upper cheek-tooth row greater than 3.7 mm; incisive foramina longer than 4.7 mm; posterior portion of septum dividing the incisive foramina very thin *Zapus princeps*
 - Length of upper cheek-tooth row less than 3.7 mm; incisive foramina shorter than 4.7 mm; posterior portion of septum dividing the incisive foramina broad *Zapus hudsonius*
3. • Mouse- and rat-like with a slender body, pointed snout, well-developed hind legs, large eyes, prominent ears, and a long tail; cheek-teeth cuspidate or, if cusp pattern not apparent, flat-crowned and prismatic not arranged as alternating triangles ↓ 4
 - Vole-like with a stout, furry body, blunt snout, short legs, small eyes, ears frequently hidden by long pelage, and tail relatively short; cheek-teeth without rows of cusps on crown; crowns flat with alternating triangles or “puddles” filled with dentine and surrounded by enamel ↓ 7
4. • Cheek-teeth appearing prismatic and flat-crowned; tail well furred and bushy *Neotoma cinerea*
 - Cheek-teeth clearly cuspidate; tail without hair ↓ 5
5. • 2 rows of cusps running down the crowns of the tooth row *Peromyscus keeni*
 - 3 rows of cusps running down the crowns of the tooth row ↓ 6
6. • Total length greater than 300 mm; 1st upper cheek-tooth (M₁) about equal to or less than combined length of M₂ and M₃ *Rattus norvegicus*
 - Total length less than 200 mm; M₁ length greater than combined length of M₂ and M₃ *Mus musculus*
7. • Tail very short, about as long as the hind foot; lower incisors set inward from the cheek-teeth, and ending in a horizontal projection opposite or in front of the socket of the last lower molar ↓ 8
 - Tail length variable but clearly extending past the hind feet when legs outstretched; lower incisors passing from the tongue to the lip sides of the cheek-teeth and ascending back to within or near the condylar process ↓ 10

8. • Pelage uniformly grizzled brown above, grayish below; upper incisors deeply grooved with projecting outer edges *Synaptomys borealis* (p. 16)
• Pelage more colorful; upper incisors not grooved ↓ 9
9. • Chestnut-brown above and without black stripe down back; cheek-teeth relatively simple with few loops; inner salient angles of upper molars and outer angles of lower molars smaller than those of the opposite side; robust skull lacking squamosal peg inside orbit *Lemmus trimucronatus*
• In summer, buff-gray above with black stripe down back, buff-gray to white below, pale or tawny ruff across throat; turn all white and develop digging claws in winter (except on Unalaska Island); cheek-teeth complex with many loops; inner and outer salient angles approximately equal in size; prominent squamosal pegs project laterally forward into orbits of the skull *Dicrostonyx groenlandicus*
10. • Pelage rust-reddish above; skull relatively rounded and light, zygomatic arches relatively slender and the mandibles weak; outer angles of cheek-teeth rounded, without a “heel” projecting posteriorly on the last upper molar (M₃) ↓ 11
• Pelage color not as above; skull relatively angular and more massive, zygomatic arches and mandibles more robust; outer angles of cheek-teeth pointed, with a “heel” projecting posteriorly on the M₃ ↓ 12
11. • Tail short, thick, with closely set bristly hairs; post-palatal bridge usually incomplete in adults, and always incomplete up through 1st year . *Clethrionomys rutilus*
• Tail longer and more slender, with short hairs except at tip where hairs longer; post-palatal bridge always complete, even in half grown young . *Clethrionomys gapperi*
12. • Flanks and venter buffy in color; ear spot usually buff or tawny; tail very short (less than 28 mm) and heavily furred and tipped with stiff tawny hairs; skull light, long, narrow and flat; prominent interorbital keel in adults, with this region being depressed ↓ 13
• Pelage color not as above; tail longer (more than 28 mm); skull more rugged as less long, narrow and flat appearing; no prominent interorbital keel or depression ↓ 14
13. • Hind foot greater than 21.5 mm; known to occur only on St. Matthew and Hall islands, Bering Sea. *Microtus abbreviatus*
• Hind foot less than 21.5 mm; inhabits the mountains on the mainland
..... *Microtus miurus*
14. • Adults exceptionally large (often 200+ mm in length, 100+ grams in weight); whisker area conspicuously rusty-yellowish in color *Microtus xanthognathus*
• Adults smaller, without conspicuous rusty-yellow snout ↓ 15
15. • Cheek-teeth (usually black in color) rooted in adults; re-entrant angles on the inner side of the lower molars deeper than those on the outer side (Fig. 3)
..... *Phenacomys intermedius*
• Cheek-teeth not rooted in adults; re-entrant angles on the inner side of the lower molars approximately equal in depth ↓ 16

- 16. • Tail averaging one-third or more of total length
..... *Microtus longicaudus*
 - Tail averaging less than 1/3 of total length ↓ 17
- 17. • 2nd upper molar (M2) with 4 closed triangles and a posterior loop
..... *Microtus pennsylvanicus*
 - M2 with 4 closed triangles and no posterior loop
..... *Microtus oeconomus*
