WATER QUALITY INTEGRATED REPORT

to

CONGRESS and the EPA ADMINISTRATOR

for the

PERIOD

January 1, 2009 to December 31, 2014

Richmond, Virginia

February 2018

ACKNOWLEDGMENTS

This report is prepared by the Virginia Department Environmental Quality (DEQ), with significant contributions from the Department of Conservation and Recreation (DCR) and the Virginia Department of Health (VDH). The information presented here is the result of long-term, extensive collaboration among state environmental and public health staff, federal agencies, inter-state partnership programs, academic institutions, local municipalities, involved citizens, and the private sector. The level of effort required to produce this report cannot be overstated.

DEQ's Water Planning Division has approximately 60 staff dedicated to the monitoring and assessment of the Commonwealth's waters. They work under the esteemed leadership of the agency's director David K. Paylor, the Water Planning Division director, and six regional directors. Monitoring and assessment staff are located in seven offices located across Virginia: Central Office (Richmond), Piedmont Regional Office (Glen Allen), Valley Regional Office (Harrisonburg), Northern Regional Office (Woodbridge), Tidewater Regional Office (Virginia Beach), Blue Ridge Regional Office (Roanoke and Lynchburg), and Southwest Regional Office (Abingdon).

Monitoring and assessment staff: Emilee Carpenter Adamson, Greg Anderson, Cleo Baker, James Beckley, Kristie Britt, Richard Browder, Matthew Carter, Martha Chapman, Mary Dail, Gabriel Darkwah, Heather Deihls, Stephen Devilbiss, George Devlin, Roger Everton, Lily Frazer, Teresa Frazier, Andrew Garey, Amanda Gray, Randy Gunn, Wick Harlan, Scott Hasinger, Kelly Hazlegrove, Nathaniel Jenkins, William Jordan, Willard Keene, John Kennedy, Andrew Kirk, Jason Hill, Phillip Hurst, Michael Hutchison, Cindy Johnson, Emma Jones, William Isenberg, Justin Loyd, Sarah Marsala, Mike McLeod, Drew Miller, Sandra Mueller, Jennifer Palmore, Jared Purnhagen, Tish Robertson, Cory Routh, Tara Sieber, Michael Shaver, Evan Shearer, James Shiflet, Rebecca Shoemaker, Antone Silvia, Warren Smigo, Donald Smith, Lanny Sparks, Royce Steiner, Brett Stern, Roger Stewart, Jeff Talbott, Bryant Thomas, Stuart Torbeck, Robert Turner, William VanWart, Kelley West, and Lawrence Willis.

Other DEQ staff who have contributed to this report are Scott Kudlas, Virginia Witmer, Elleanore Daub, Michelle Henicheck, Kelly Ward, Megan Quinn, Bill Keeling, Anne Schlegel, and Nicole Sandberg. Contributing authors from non-DEQ agencies: Karl Huber (DCR) and Margaret Smigo (VDH).

Most of the sample analysis that renders this report possible is performed by the Virginia Department of Consolidated Laboratory Services.

DEQ appreciates the data provided by its community partners such as Virginia Save Our Streams, the Alliance for the Chesapeake Bay, and StreamWatch. Academic institutions such as Longwood University, Virginia Commonwealth University, the Virginia Institute of Marine Science, and Old Dominion University are also important components of DEQ's non-agency monitoring network.

Lastly, the United States Environmental Protection Agency provides guidance and oversight for this report and the activities required to produce it. Other federal agencies and inter-state programs that work in conjunction with DEQ include the United States Geological Survey, National Park Service, United States Fish and Wildlife Service, the National Oceanic and Atmospheric Administration, and the Federal-Interstate Chesapeake Bay Program.

TABLE OF CONTENTS

EXECUTIVE SUMMARY..... i

CHAPTER 1: INTRODUCTION..... 1

CHAPTER 2: STATE BACKGROUND INFORMATION..... 6

CHAPTER 3: SURFACE WATER MONITORING..... 9

3.1 Freshwater Biological Monitoring Program..... 12

3.2 Estuarine/Coastal Probabilistic Monitoring Program..... 13

3.3 Estuarine Benthic Macroinvertebrate Monitoring Program..... 17

3.4 Beach Monitoring Program..... 18

3.5 Citizen and Non-Agency Water Quality Monitoring Program..... 22

CHAPTER 4: SURFACE WATER QUALITY ASSESSMENT..... 41

4.1 Assessment Methodology..... 41

4.2 Statewide Water Quality Assessment Summary..... 50

4.3 Individual River Basin Assessment Results..... 59

4.4 Freshwater Probabilistic Monitoring Results…..... 91

4.5 Estuarine Probabilistic Monitoring Results..... 109

4.6 Chesapeake Bay Assessment Results..... 136

CHAPTER 5: NONPOINT SOURCE ASSESSMENT..... 160

CHAPTER 6: GROUNDWATER PROGRAMS/ASSESSMENT..... 175

CHAPTER 7: WATER QUALITY PROGRAMS..... 189

7.1 Water Pollution Control Programs (VPDES and TMDLs)..... 189

7.2 303(d) Program Visions……. 198

7.3 Pollution Prevention Programs……..... 203

7.4 Cost/Benefit Associated with the Construction Assistance Program..... 205

7.5 Public Health/Aquatic Life Concerns..... 208

7.6 Coastal Resources Management Program Initiatives..... 234

7.7 Chesapeake Bay Program Initiatives..... 246

7.8 Wetlands Program Initiatives..... 250

7.9 Regional Water Quality Initiatives..... 259

APPENDICES

1 Integrated List of All Waters in Virginia

1a List of Category 5 Impaired Waters

1b Supplemental List of Category 5 Waters Newly Impaired in 2016

1c List of Category 4A Impaired Waters

1d List of Category 4C Impaired Waters

1e List of New Category 4C Impaired Waters in 2016

2 Water Quality Based Limited Sources - Category 4B and 5E Waters

2a Category 4B and 5E Waters Approved for Delisting since the 2014 Report

3 Waters Identified for Delisting since 2014 Report

4 Water Identified for Delisting since 2014 Report for Designated Use Removal

5 Fact Sheets for Category 5 Waters

6 Clean Water Act References

7 List of Significant Lakes

8 Current Status of TMDL Development in Virginia

9 Assessment Monitoring Station List

EXECUTIVE SUMMARY

Virginia's 2016 Water Quality Assessment Integrated Report (IR) is submitted in compliance with the water quality reporting requirements under Sections 305(b), 303(d), 106, 314 and 319 of the Federal Clean Water Act and the Virginia Water Quality Monitoring, Information and Restoration Act (Section 62.1-44.19:5 C of the Code of Virginia). The 2016 IR provides the results of Virginia's water quality assessments during the time period January 1, 2009 through December 31, 2014, and describes the extensive efforts to monitor, assess, and improve water quality in the waters of the Commonwealth. The information in this report is intended to educate the public about Virginia's water quality conditions and as a tool in planning and management of waters in the Commonwealth.

Overview of Assessment Results

A primary objective of the IR is to determine whether the Commonwealth's waters support their applicable designated uses as mandated by Section 305(b) of the Clean Water Act. There are six designated uses that may be applied to surface waters: aquatic life, fish consumption, shellfishing, recreation, public water supply, and wildlife. Virginia's water quality standards define the water quality needed to support each of these uses by establishing the numeric criteria that physical and chemical data are assessed against. If a waterbody contains more of a pollutant than is allowed by the water quality standards, it will not support one or more of its designated uses. Such waters are considered to have "impaired" quality. An "impairment" refers to an individual parameter or characteristic that exceeds a water quality standard. A water fails to support a designated use when it has one or more impairments.

Between January 2009 and December 2014 DEQ staff visited 4,205 stations located in Virginia's lakes/reservoirs, rivers, and estuaries. At these stations, DEQ collected 120,309 measurements of temperature, 96,240 measurements of pH, and 118,910 measurements of dissolved oxygen. A subset of these water samples were also analyzed for nutrients, suspended solids, bacteria, metals, pesticides, herbicides, and toxic organic compounds. Over 600 different parameters were analyzed. In addition to this large dataset, data collected by over 100 citizen monitoring groups and governmental partners were used by DEQ to assess the status of Virginia's waters. Chapter 3 provides more information about these monitoring programs.

Table A provides a summary of the statewide assessment results for the 2016 IR reporting period. Statewide, 7,116 stream miles, 20,318 acres of lakes/reservoirs, and 315 square miles of estuarine waters meet all designated uses for which they were assessed[1]. This represents measurable progress since the 2014 IR, as indicated in Table A below. The improvements in assessment status are attributed to new data collected to support impairment delists and newly assessed waters that previously had insufficient data to complete an assessment. The total impaired river miles reported in the 2016 IR is 15,282, which represents a slight decrease from the 2014 IR reported mileage of 15,679. While the Commonwealth added 871 newly impaired river miles in the 2016 IR, this was largely offset by new impairment delists. The acres of lakes reported as impaired in the 2016 IR is 93,523, which is a decrease from the 2014 IR reported

[1] The majority of these waters fall within assessment Category 2; fully supporting some Uses but insufficient data to assess all Uses.

value of 94,754. Similarly, the square miles of estuarine waters reported as impaired in the 2016 IR is 2,132, which is a slight decrease from the 2014 IR reported value of 2,136. The decreases in impaired acres of lakes and square miles of estuarine waters is largely attributed to impairment delists.

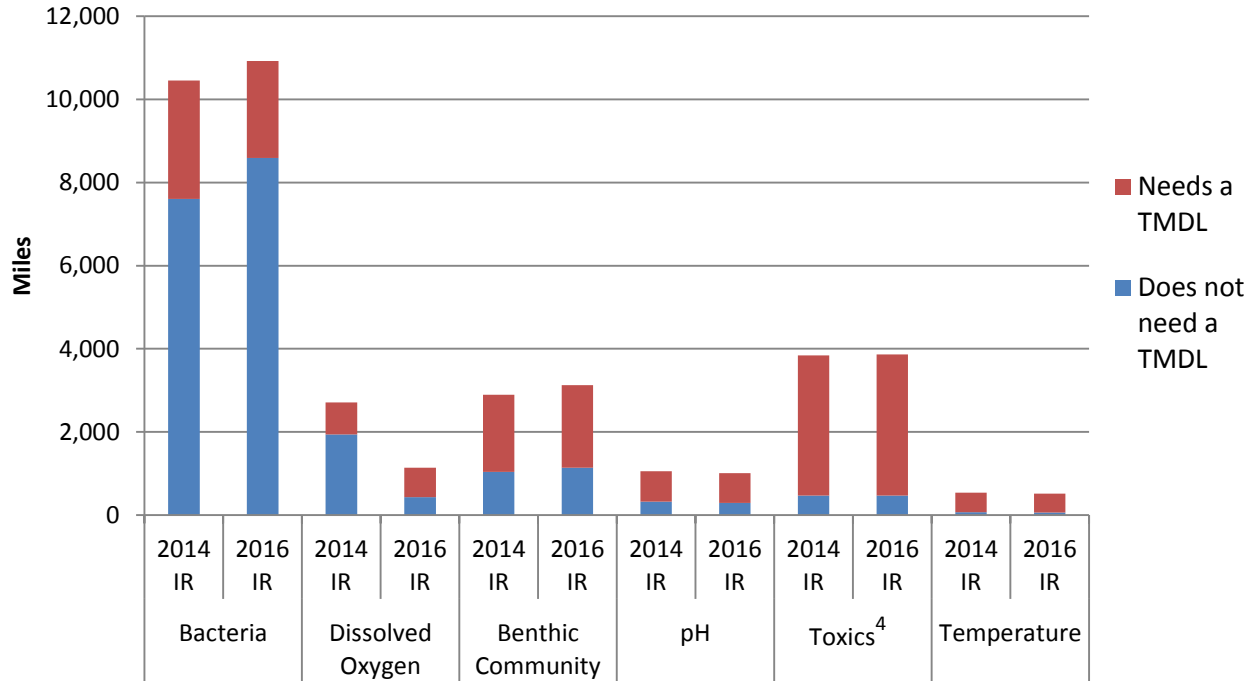
Table A. Overview of assessment results. Improvements since the 2014 IR, shown as percent change, are in green font.

	Rivers (mi)	Lakes (acres)	Estuaries (sq mi)
Impaired (% total)	15,282 (15%)	93,523 (80%)	2,132 (75%)
Percent change from 2014	***-2.5%***	***-1.3%***	***-0.2%***
Non-Impaired (% total)	7,116 (7%)	20,318 (17%)	315 (11%)
Percent change from 2014	***10.4%***	***4.4%***	***1.6%***
Not Assessed (% total)	78,576 (78%)	3,373 (3%)	400 (14%)
Percent change from 2014	***-0.3%***	*13.6%*[2]	*2.5%*
TOTAL	100,974	117,215	2,848

Prior to the development of the 2014 IR, DEQ adopted the 1:24,000 scale resolution of the National Hydrography Dataset (NHD) in its water quality assessments. The conversion of Virginia's older 1:100K to the higher resolution 1:24K NHD resulted in a significant increase in mapped stream mileage, and, consequently, a higher percentage of waters considered "not assessed" due to the inclusion of previously unmapped waterways—mostly small unnamed tributaries[3]. These waters are counted as "unassessed" until they are monitored and properly characterized by DEQ staff. However, DEQ's freshwater probabilistic monitoring program, described in chapter 4.4, includes coverage of small unnamed tributaries as part of the randomly generated station locations. While much of the data generated by probabilistic monitoring is not formally assessed, the data is used to answer questions about statewide and regional water quality conditions, and to identify problem areas for follow-up monitoring.

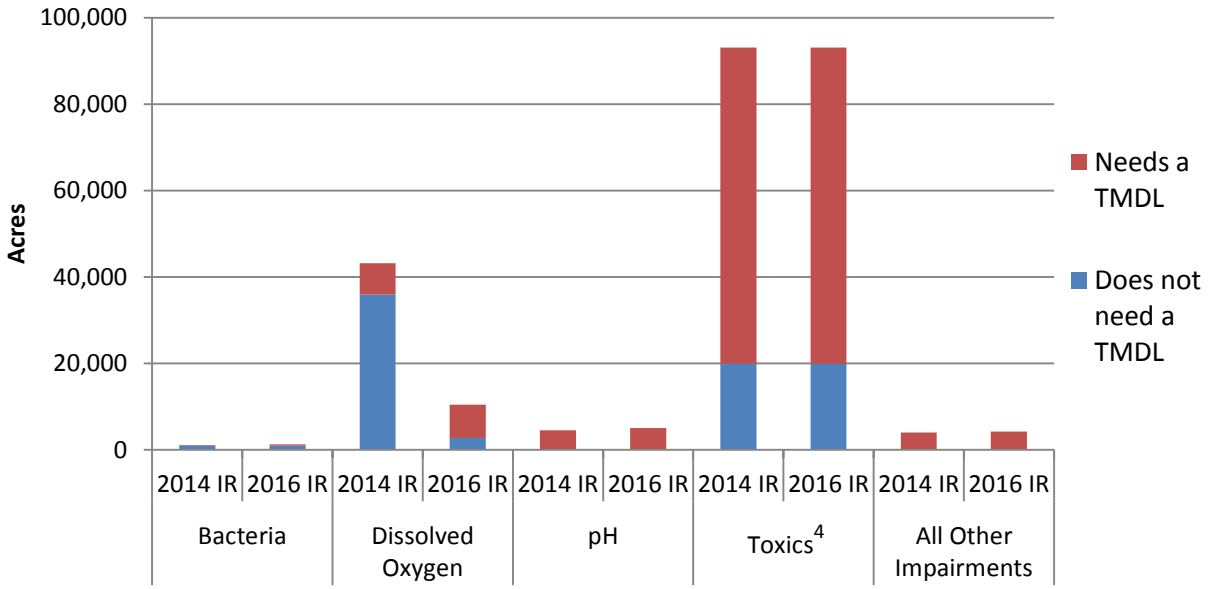
The assessment status of the Commonwealth's designated uses is summarized in Chapter 4.2. Many of the Commonwealth's waters contain data indicating a "supporting" status for one or more designated uses. The aquatic life, wildlife, public water supply, and shellfishing designated uses are reported as "supporting" most frequently. The recreation use is impaired in the most number of waters; 49% of assessed rivers/streams (10,926 miles), 1% of assessed

[2] Includes waterbodies that have been previously assessed but do not have data in the current assessment window. Some of these waters will be reviewed during the 2018 assessment period.



[3] DEQ does not anticipate significant changes to the resolution of its surface water mapping in the foreseeable future; though it is likely statewide stream mileage will decrease slightly as intermittent, ephemeral streams are better distinguished from perennial waters.

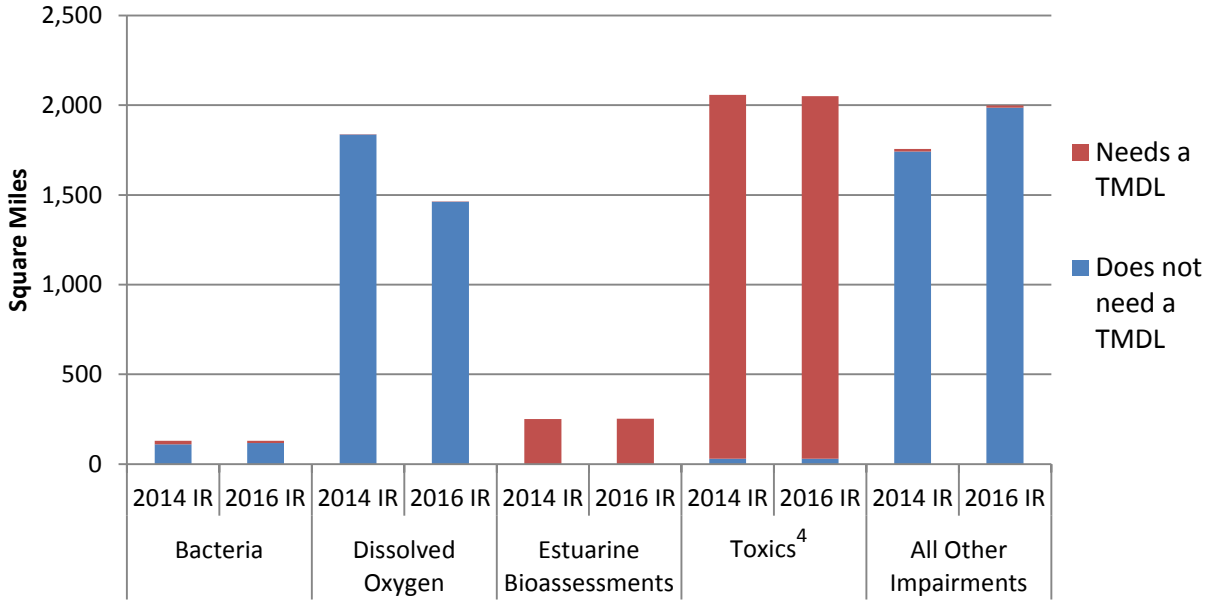
lake acres (1,248 acres) and 3.8% of assessed estuarine waters (92 square miles) are impaired for this use. Elevated levels of the indicator bacteria Escherichia coli (E. coli) are the most significant cause for this use impairment, mainly affecting rivers. Agricultural practices, urban runoff, leaking sanitary and storm sewers, failing septic systems, wildlife and domesticated animals are contributors of E. coli. The aquatic life use is also not supported in many rivers; 23% of assessed rivers/streams (5,159 miles), 13.6% of assessed lake acres (15,439 acres) and 86% of assessed estuarine waters (2,110 square miles) are impaired for this use. Low dissolved oxygen concentration (hypoxia) is the most prevalent cause of aquatic life use impairment. Nutrient enrichment, also known as eutrophication, can cause hypoxia by contributing to the formation of oxygen-depleting algae blooms. Low dissolved oxygen is a common impairment of lakes and estuarine waters, including the Chesapeake Bay. Evidence of a degraded biological (benthic) community is another strong indicator that a waterbody does not support the aquatic life use. Finally, the fish consumption designated use is also reported as not supported in many waters of the Commonwealth; 16% of assessed rivers/streams (3,590 miles), 75% of assessed lake acres (85,755 acres) and 84% of assessed estuarine waters (2,049 square miles) are impaired for this use. PCBs and/or Mercury in fish tissue are the most prevalent cause of the fish consumption use impairment.



The impairment status of Virginia's rivers, lakes, and estuaries is illustrated in Figure A below. The blue portion of each graph characterizes the size of the waterbody that is impaired but does not need a Total Maximum Daily Load (TMDL) plan because a TMDL is already complete (assessment Category 4A), another form of pollution control plan is in place (assessment Category 4B), the water quality condition is considered natural (assessment Category 4C), or for some other reason the water does not require a TMDL. The red portion of the graph represents the size of the waterbody that is impaired and still requires TMDL development (assessment Category 5). As evident in the figures below, the Commonwealth has made significant progress on completing TMDL plans for many impairments, including bacteria, benthics, and dissolved oxygen, while other impairments, such as toxics in fish tissue, still require a TMDL. DEQ currently has TMDL projects underway to address toxics in fish tissue in the New River and lower James River basins, and is initiating a TMDL study to address toxics in fish tissue in the upper James River. Chapter 7.2 provides more information on the prioritization process for TMDL development through 2022.

Figure A. Summary of impaired waters as reported in the 2014 and 2016 Integrated Reports. Differences between reporting periods reflect both proposed delistings and new impairment listings.

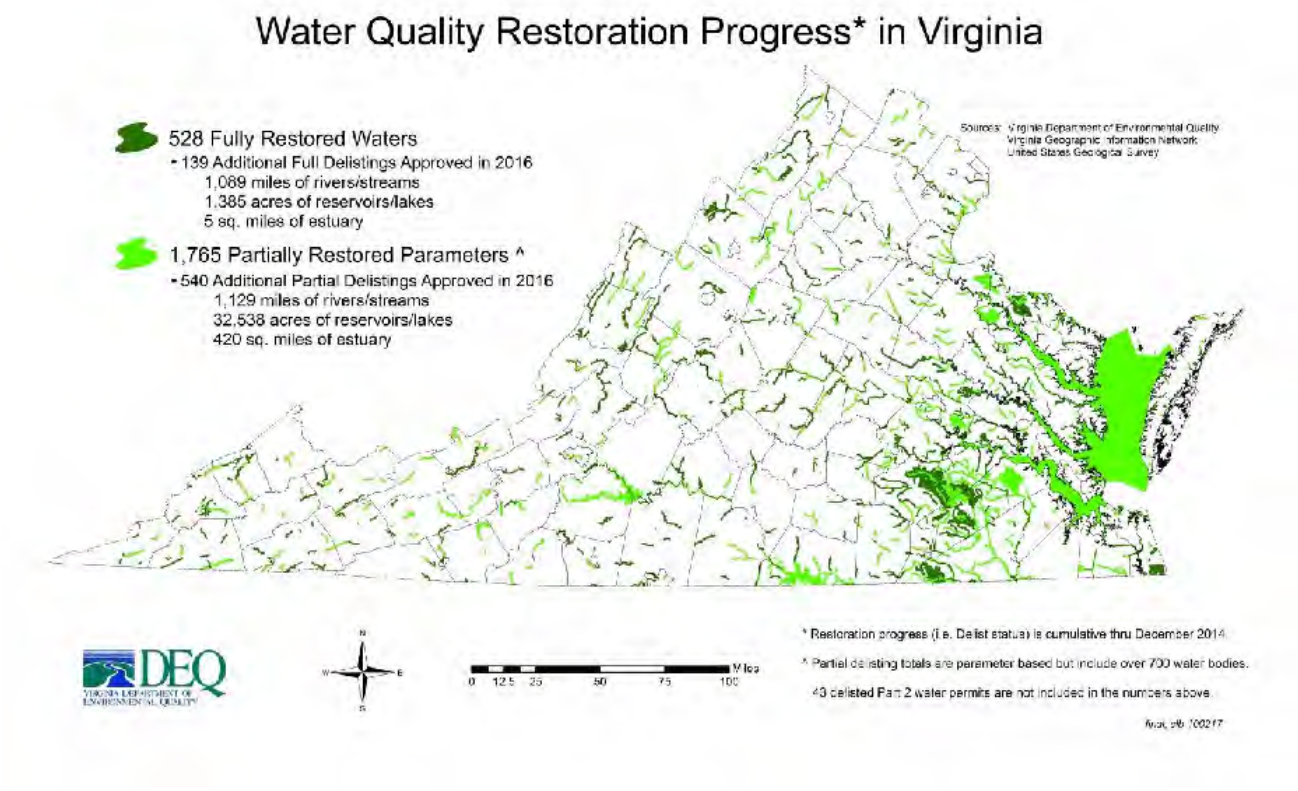
a. Stream miles



b. Acres of lakes

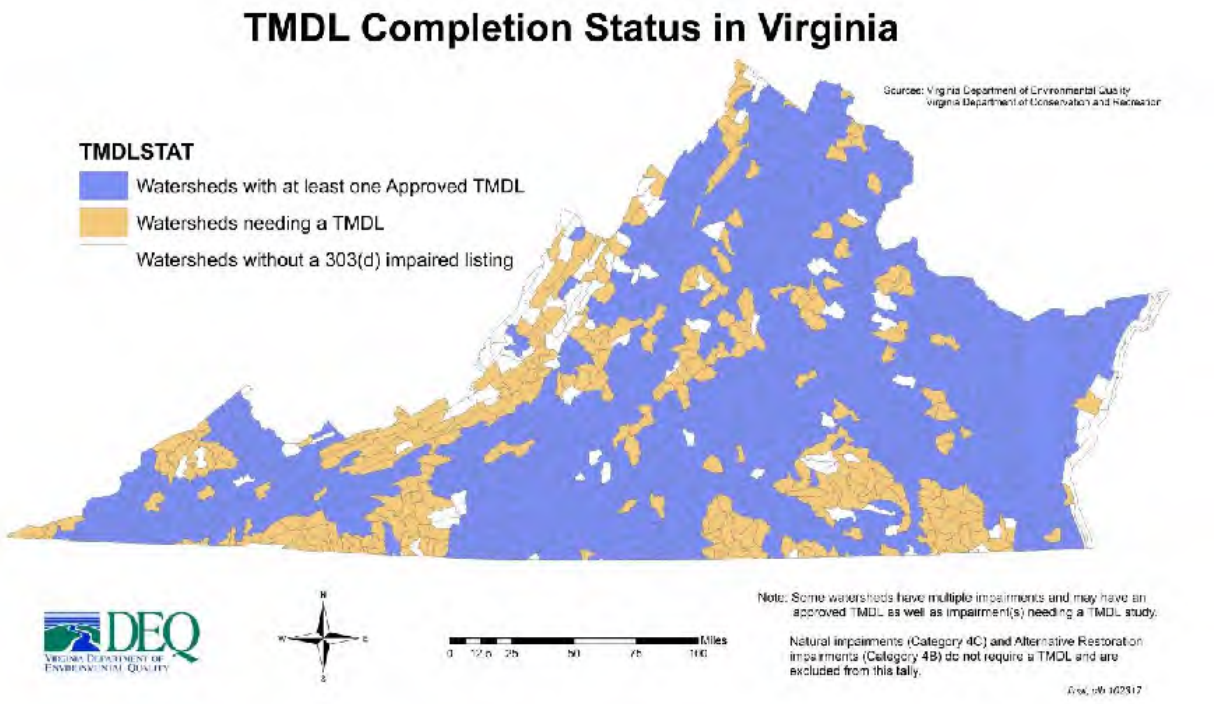
[4] The overwhelming majority of toxics impairments in rivers, lakes and estuaries are due to exceedences of thresholds for PCBs and Mercury in fish tissue.

c. Square miles of estuarine waters



Appendix 1 provides the list of impaired waters, which can be visualized using DEQ's mapping application found here: http://www.deq.virginia.gov/ConnectWithDEQ/VEGIS.aspx. Detailed assessment results at state-wide and basin-wide scales are found in Chapters 4.2 and 4.3, respectively. Chapter 4.6 provides the assessment results specific to the Chesapeake Bay and its tributaries.

Water Quality Improvements and Total Maximum Daily Loads



Water quality assessment also identifies those waters that were previously listed as impaired but now currently meet standards. Impairment causes of impaired waters are "delisted" from the 303(d) List of Impaired Waters after justification is provided to EPA, the proposed removal is announced to the public, and the removal is approved by EPA. An impairment can be delisted for a number of reasons. First, if a water quality standard is officially changed through rule-making, waters that previously failed that standard may now meet it. Second, if the assessment methodology for a particular standard has been modified, a water may now meet the standard. Third, a cause can be delisted if new data indicate that water quality standards are currently being attained. This can be the result of successful pollution control efforts, but sometimes the reason for recovery is unknown. For the 2016 assessment, DEQ has delisted 681 causes, tracked by waterbody size (see Figure B). The most common delisted impairment is dissolved oxygen. The decline in dissolved oxygen impairments since the 2014 IR can be partially attributed to improvements in DO concentration observed in lakes and in the tidal waters of the Chesapeake Bay during the 2012-2014 time period. See Appendix 3 for the list of waters with delisted impairments.

Figure B. Distribution of waters with causes that have been removed from the 303(d) List of Impaired Waters. (Full delists are waters in which all known impairments have been removed from the list).

Water quality assessment serves as the first step in the development of Total Maximum Daily Loads (TMDLs). TMDLs can be viewed as a "pollution diet" for a particular water, prescribing the maximum level (or "load") of a pollutant that the water can handle before it violates water quality standards. To date, DEQ has completed 917 TMDLs. Most have been focused on eliminating bacteria impairments. Figure C shows the sub-watersheds where TMDLs have been developed or completed. Chapter 7.1 provides more information regarding DEQ's TMDL program.

Figure C. Sub-watersheds containing TMDLs

Other Water Quality Information

Most of the information in this report pertains to the condition of surface waters (freshwater rivers, lakes/reservoirs, and estuaries). But surface water is only one component of Virginia's water resources. DEQ is charged with characterizing, protecting, and improving all waters. Chapters 6, 7.6, and 7.8 discuss programs focused on the protection of groundwater, coastal waters, and wetlands.

EPA defines threatened waters as those waters that are predicted to exceed water quality standards during the next 305(b) reporting cycle and therefore, considered needing a TMDL. DEQ believes impairment should be confirmed by current monitoring data, using rigorous assessment methodology, before scheduling TMDL development. However, DEQ does identify "at-risk" waters using probabilistic monitoring in freshwater, free-flowing wadeable streams (ProbMon). Chapter 4.4 and Chapter 4.5 provide the latest probabilistic survey results of Virginia's waters.

Modifications to assessment procedures since the 2014 Integrated Report (IR) are detailed in Part II of the Final 2016 Water Quality Assessment Guidance Manual. The most notable change pertains to how waterbodies are prioritized for TMDL development. Chapter 7.2 discusses this new prioritization scheme.

CHAPTER 1 INTRODUCTION

The Virginia Department of Environmental Quality (DEQ) is responsible for protecting and enhancing Virginia's environment and for promoting the health and well-being of the citizens of the Commonwealth. The agency administers state and federal environmental laws and regulations pertinent to air and water quality, water supply, and land protection and revitalization. DEQ's two Water Divisions (Water Permitting and Water Planning) are responsible for carrying out the mandates of the State Water Control Law, as well as meeting Virginia's federal obligations under the Clean Water Act. DEQ administers state laws and regulations to improve and protect Virginia's streams, rivers, bays, wetlands and ground water for aquatic life, human health and other beneficial water uses. Water monitoring programs, the water quality standards program, water quality assessments, Total Maximum Daily Load plans and permitting under the Virginia Pollution Discharge Elimination System (VPDES), the Virginia Water Protection (VWP) and the Virginia Pollution Abatement (VPA) programs are vital instruments DEQ uses to carry out its duties. Please visit DEQ's Water Programs website to learn more about these programs and others.

Objectives and Federal Requirements

Under the Clean Water Act, EPA requires that each state develop a program to monitor the quality of its surface and ground waters and prepare a report every two years describing the status of its water quality. Each state identifies waters of concern as having observed effects and schedules additional monitoring, if appropriate, to determine if designated uses are being met. EPA issues guidelines for states to use during the reporting cycle for national consistency purposes. States are encouraged to use these guidelines to prepare these water quality reports for EPA. EPA compiles the data from the state reports, summarizes them, and transmits the summaries to Congress, including an analysis of water quality nationwide. This 305(b)/303(d) process is the principal means by which the EPA, Congress, and the public evaluate current water quality, the progress made maintaining and restoring water quality, and the extent of remaining work to be done. Many states, including Virginia, rely on the 305(b)/303(d) process for information needed to conduct water quality planning. The 305(b)/303(d) process is an integral part of Virginia's water quality management program, for which requirements are set forth in 40 CFR 130.

Section 305(b) of the Clean Water Act requires each state to submit a biennial report to EPA describing the quality of its navigable waters. The 305(b) report provides DEQ's best overall assessment of water quality conditions and trends in the Commonwealth. The report is intended to be used as a tool in planning and management of waters in Virginia. The report also directs continuous planning and implementation activities in coordination with the State Water Quality Management Plan and the Continuous Planning Process (CPP).

Primary objectives of a 305(b) report are:

1. To educate and inform citizens and public officials about Virginia's overall water quality.

2. To analyze water quality data to determine the extent to which Virginia's waters are supporting the designated uses for all state waters and to compare the results to water quality standards and other appropriate criteria and guidelines.

3. To determine the causes of non-attainment of designated uses in the State's waters.

4. To determine the nature and recognizable extent of point and nonpoint source impacts in accordance with state and federal guidelines.

Section 303(d) of the Clean Water Act and the Environmental Protection Agency's regulation 40 CFR, Section 130.7 (d) requires each state to submit a Total Maximum Daily Load (TMDL) Priority List for impaired waters to EPA on April 1 of even numbered years. This list is provided in Appendix 1a.

In summary, the Integrated Report provides the following information relating to:

- the delineation of water quality assessment units (AUs) based on National Hydrography Dataset (NHD);
- the status of and progress toward achieving comprehensive assessments of all waters;
- the attainment status of designated uses for every AU assessed;
- additional monitoring that may be needed to determine designated use support status and, if necessary, to assist development of TMDLs for each pollutant/AU combination;
- schedules for additional monitoring planned for AUs;
- pollutant/AU combinations still requiring TMDLs; and
- TMDL development schedules reflecting the priority ranking of each pollutant/AU combination.
- "Effluent Limited" Waters.

Assessment Scheme

The 305(b) process assesses six primary designated uses, as appropriate for a particular waterbody, based on water quality standards:

Aquatic Life Use: supports the propagation, growth, and protection of a balanced indigenous population of aquatic life which may be expected to inhabit a waterbody. In Chesapeake Bay waters (mainstem and tributaries), this use is divided into sub-uses that target specific aquatic life assemblages.

Recreation Use: supports swimming, boating, and other recreational activities.

Fish Consumption Use: supports game and marketable fish species that are safe for human health.

Shellfishing Use: supports the propagation and marketability of shellfish (clams, oysters, and mussels).

Public Water Supply Use: supports safe drinking water.

Wildlife Use: supports the propagation, growth, and protection of associated wildlife.

The 2016 EPA Integrated Report Guidance and Assessment Database (ADB V2.3.1) continues to use five categories ("category 4" having three subcategories) in which every assessment unit (AU) should be placed based on designated use attainment. Additionally, Virginia has devised several other sub-categories to supplement the federal categories, enabling a more precise system of tracking and reporting.

Below are the EPA defined categories followed by associated Virginia defined subcategories**:**

***FULLY SUPPORTING* - Waters are supporting one or more designated uses**

- **EPA Category 1 -** Attaining all associated designated uses and no designated use is threatened

  Va. Category 1A - waters are attaining all uses and a TMDL has been developed for one or more uses.

- **EPA Category 2 -** Available data and/or other information indicate that some, but not all of the designated uses are supported.

  Va. Category 2A - waters are supporting all of the uses for which they are monitored.

  Va. Category 2B - waters are of concern to the state but no water quality standard exists for a specific pollutant, or the water exceeds a state screening value or toxicity test.

Va. Category 2C - waters are now attaining the use(s) for which they were originally 303(d) listed and the TMDL is EPA approved but other applicable use(s) were not monitored and assessed.

***INDETERMINATE* - Waters needing additional information**

- **EPA Category 3 -** Insufficient data and/or information to determine whether any designated uses are met.

  Va. Category 3A - no data are available within the data window of the current assessment to determine if any designated use is attained and the water was not previously listed as impaired.

  Va. Category 3B - some data exist but are insufficient to determine support of designated uses. Such waters will be prioritized for follow-up monitoring, as resources allow.

  Va. Category 3C - data collected by a citizen monitoring or another organization indicating water quality problems may exist but the methodology and/or data quality has not been approved for a determination of support of designated use(s). These waters are considered as having insufficient data with observed effects. Such waters will be prioritized by DEQ for follow-up monitoring.

  Va. Category 3D - data collected by a citizen monitoring or other organization indicating designated use(s) are being attained but the methodology and/or data quality has not been approved for such a determination.

***IMPAIRED* - Waters are impaired or threatened but a TMDL is not required.**

- **EPA Category 4A -** water is impaired or threatened for one or more designated uses but does not require a TMDL. A new TMDL is not necessary to address the newly identified impaired tributaries if TMDL modeling, source identification and reductions cover the entire watershed and the TMDL has been approved by EPA. These waters are primarily related to shellfish and/or recreational bacteria impairments but could include benthic impairments.

- **EPA Category 4B -** water is impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements (such as VPDES limits under a compliance schedule) are reasonably expected to result in attainment of water quality standards by the next reporting period or permit cycle.

- **EPA Category 4C -** water is impaired or threatened for one or more designated uses but does not require a TMDL because the impairment is not caused by a pollutant and/or is determined to be caused by natural conditions.

  Va. Category 4D - part(s) of a water quality standard is attained for a pollutant with a TMDL, but the remaining criteria for the standard were not assessed due to insufficient information. (Only to be applied to dissolved oxygen in tidal waters of the Chesapeake Bay).

***IMPAIRED* - Waters are impaired or threatened and require a TMDL**

- **EPA Category 5 - Waters are impaired or threatened and a TMDL is needed.**

  Va. Category 5A - a water quality standard is not attained. The water is impaired or threatened for one or more designated uses (excluding shellfish use) by a pollutant(s) and requires a TMDL (303d list).

  Va. Category 5B - the water quality standard for shellfish use is not attained. One or more

pollutants causing impairment require TMDL development.

Va. Category 5C - the water quality standard is not attained due to "suspected" natural conditions. The water is impaired for one or more designated uses by a pollutant(s) and may require a TMDL (303d list). Water quality standards for these waters may be re-evaluated due to the presence of natural conditions.

Va. Category 5D - the water quality standard is not attained where TMDLs for a pollutant(s) have been developed but one or more pollutants are still causing impairment requiring additional TMDL development.

Va. Category 5E - effluent limited facilities are not expected to meet compliance schedules by next permit cycle or reporting period.

Va. Category 5F - the water quality standard is attained for a pollutant(s) with a TMDL and 303(d) delisting approved but the water remains impaired for additional pollutant(s) requiring TMDL development.

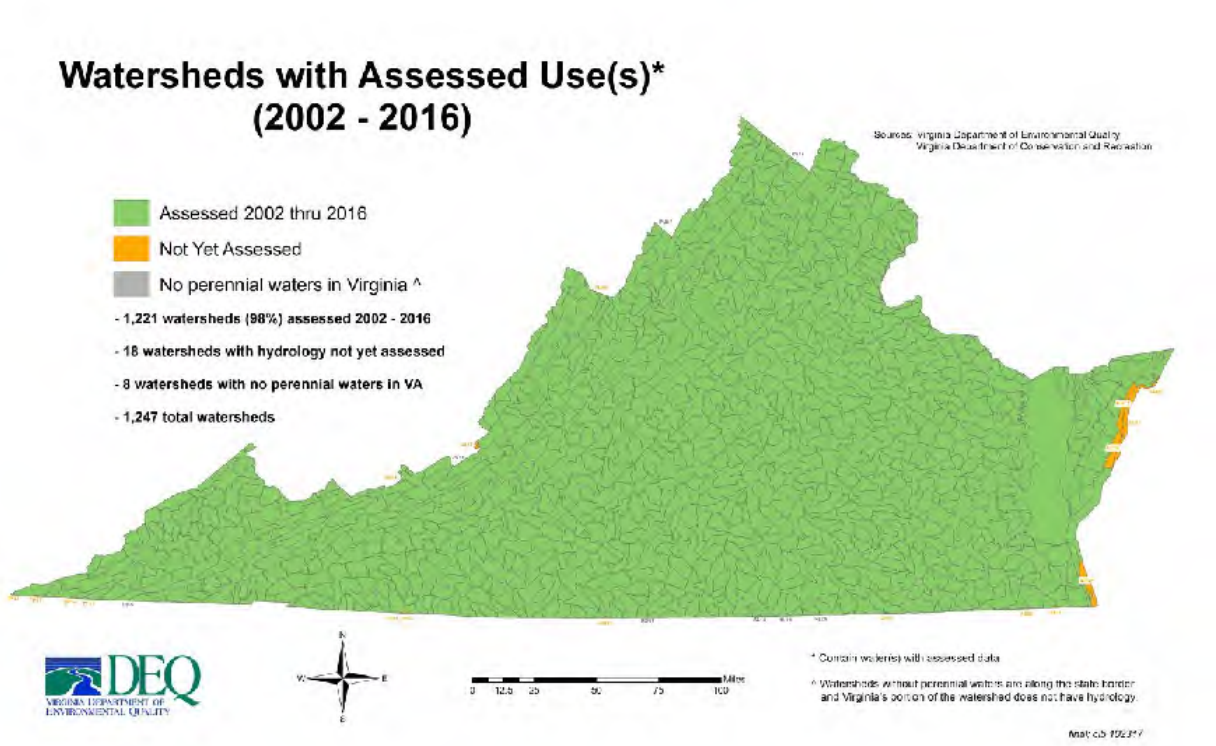
Va. Category 5R - the Water Quality Standard is not attained and the water is impaired, and implementation of an EPA-approved restoration plan is expected to result in attainment. A status update will be provided each 303(d) cycle to evaluate progress.

- **EPA Category 5M** - the water quality standard is not attained for mercury primarily due to atmospheric deposition.

Data Used To Determine Water Quality

There are two basic types of water quality data used in the assessment process. The primary type is "monitored" data approved through the quality assurance/quality control process (QA/QC). The data come from the analysis of chemical, biological, and/or physical samples collected by DEQ or by individuals and organizations that have been approved by DEQ. These data are considered to be of the highest quality. Generally, states compile their lists of impaired waters using only monitored data, which are generated using EPA-accepted sampling and analytical methods. All non-DEQ monitoring data submittals used in an assessment, except chemical data submittals from the U.S. Geological Survey (USGS), must include a sampling and analysis protocol for DEQ review.

The second type of data used in the assessment is considered "evaluated" data. These physical, chemical, and biological data are primarily obtained from sources without an EPA-approved or DEQ-accepted sampling protocol. These data are considered to be of lower quality than monitored data. Normally, these data are not used directly for listing waters as impaired, but may be used to identify observed effects that may trigger additional follow-up monitoring.



Non-DEQ water quality data continue to be tremendously valuable to the assessment process. The data generated by citizen groups, the private sector, and other governmental agencies extend the reach of DEQ's monitoring network. Quality assurance and quality control (QA/QC) continue to be a concern for regulatory use of "outside" data, and DEQ has made a considerable effort to improve the data quality of outside data providers by reviewing monitoring protocols and holding training events. DEQ's objective is to certify additional non-DEQ QA/QC data, with the consent of contributors, for future designated use determination in the overall statewide water quality assessment.

DEQ welcomes submission of both monitored and evaluated data. Data submittals are accepted continuously. Data should be submitted for review through March 30th of the previous odd-year to be considered for inclusion in the next even-year assessment report. Chapter 3.5 provides more information about DEQ's citizen monitoring program.

On-going Refinement to the Assessment Process

DEQ has again used a six-year assessment data window for the 2016 report. This data window follows a 2006 update to the ambient water monitoring strategy for Virginia, which has incorporated all 1,247 12-digit (6th Order) sub-watersheds into the existing rotating watershed monitoring approach. This approach uses a two-year, semi-monthly monitoring scheme, as described in Chapter 3.1, prior to rotating to another sub-watershed. This approach is designed to cover one-third of these smaller sub-watersheds throughout the state every two years. Thus, after six years, almost every sub-watershed within the state is scheduled to be monitored. This is the third assessment report to fully reflect this updated watershed rotation scheme. Figure 1 shows the spatial coverage of DEQ's ambient water monitoring program since 2002.

Figure 1. Map with sub-watersheds assessed since the 2002 report

CHAPTER 2 STATE BACKGROUND INFORMATION

Population

The Commonwealth of Virginia covers 42,775 square miles and ranks 35th among the states in size. This area is divided into six Department of Environmental Quality (DEQ) regional offices, with two satellite offices. According to the most recent census (2010), the population of the Commonwealth was estimated to be 8,001,024 or 2.5% of the total United States population. It has grown approximately 13% between 2000 and 2010, ranking 12th nationally, and continues to grow. Approximately 72% of all Virginians live in eight metropolitan areas: Northern Virginia, Norfolk-Virginia Beach-Newport News, Richmond-Petersburg, Roanoke, Lynchburg, Charlottesville, Danville and Johnson City-Kingsport-Bristol. Approximately 9% of the population lives in seven smaller urban areas and 19% live in rural areas.

Geography

Virginia is over 400 miles in length along its southern boundary, reaching from the Atlantic Ocean in the east, crossing the eastern continental divide into the Mississippi Basin to the west. Along the way, Virginia crosses five physiographic provinces. The southwestern edge of the state touches upon the margin of the Cumberland Plateau, which is characterized by rugged terrain with formations of sandstone and shale. Virginia's coal mining industry is concentrated in this area. The Valley and Ridge province encompasses the long, parallel ridges of the Appalachian Mountain chain in western Virginia. Erosion-resistant quartzites and sandstones form the ridgetops, while streams have carved valleys into the softer limestones and shales. The narrow Blue Ridge Mountain province is made up of hard greenstone, quartzites, and granites, igneous and metamorphic rocks that originated as ancient lava flows. These mountains are among the oldest on earth. East of the Blue Ridge Mountains lies the rolling Piedmont district of central Virginia. A complex layer of igneous and metamorphic rocks underlies this area. The Triassic Basins, ancient down-faulted basins filled with sedimentary rocks and igneous intrusions are major sub-units of this province. A distinctive fall line, marked by waterfalls and rapids across the major rivers, divides the Piedmont from the Coastal Plain. Virginia's flat Tidewater area consists of deep, unconsolidated deposits of sand, gravel, fossil shells, and clay. The basement formation of granite, exposed at the fall line, is buried under 2,900 feet of sediment at the Atlantic Coast.

Water Resources

A summary of Virginia's water resources is provided in Table 2-1. Virginia has an estimated 100,923 miles of streams and rivers divided into nine major river basins. This estimate represents mileage determined by the United States Geological Survey National Hydrography Dataset (NHD). Annual rainfall averages almost 43 inches. Total combined flow of all freshwater streams in the state is estimated at about 25 billion gallons per day. The 248 publicly owned lakes in the Commonwealth have a combined area of 117,158 acres. Of these lakes, 123 are considered “significant lakes” for monitoring purposes, totaling approximately 113,545 acres. Many hundreds of other smaller, privately owned lakes, reservoirs and ponds, some of significant size, dot the landscape.

Other important water features of Virginia include approximately 236,900 acres of tidal and coastal wetlands, 808,000 acres of freshwater wetlands, 120 miles of Atlantic Ocean coastline, and approximately 2,308 square miles of Chesapeake Bay estuarine waters. Virginia's highly indented shoreline, including the Chesapeake Bay and its sub-estuaries, is conservatively estimated to be 3,315 miles long.

Table 2-1 Virginia Water Resources Atlas

State Population (2006 census) – 7,642,884
(2010 census) – 8,001,024

State Surface Area – 42,775 square miles

Major River Basins

Potomac/Shenandoah	Tennessee/Big Sandy
James	Chesapeake Bay/Small Coastal
York	Rappahannock
Roanoke/Yadkin	New
Chowan/Dismal Swamp	

Total Non-Tidal River/Stream Miles - 100,923

Miles of Border River (Potomac) - 180

Publicly-Owned Significant Lakes and Reservoirs - 123

Significant Lake/Reservoir Acres - 117,158

Total Acres of Palustrine Wetlands - 1,075,443
Total Acres of Riverine Wetlands - 380
Total Acres of Lacustrine Wetlands - 193
Total Acres of Estuarine Wetlands - 190,996
Total Acres of Isolated Wetlands - ≈ 250,000

Estuary Square Miles (excluding small coastal areas) - 2,308

Atlantic Ocean Coastal Miles – 120

Total Coastal Shoreline Miles Including Chesapeake Bay and Tidal Tributaries to a Width of 110 Feet - 3,315

Statewide Average Annual Rainfall - 42.8 inches

Average Freshwater
Discharge of All Rivers – Approximately 25 billion gallons per day

Land Use

Virginia's landscape is dominated by forests, which cover approximately 57% of the state's total area (Table 2-2). However, according to USDA's *Virginia's Forests, 2007*, forested area has declined by less than 1% since 2001. Most (60%) of the loss can be attributed to expanding urban land use, 30% to agriculture, and the rest to other land uses. Water quality is greatly impacted by land use. Specifically, high quality waters are most commonly associated with forested areas. Forested ecosystems act as natural filters, absorbing nutrients and other pollutants that would otherwise be washed into nearby waterbodies. Water quality can be protected in developed areas by creating vegetated buffer zones and maintaining sewer infrastructure.

Table 2-2 Virginia Statewide Land Use Summary

Commercial Forests	23,818 mi^2	97%
Reserved/Unproductive Forests	752 mi^2	3%
Total Forested Land[1]	**24,570 mi^2**	**57%**
Harvested Cropland	4091 mi^2	32%
Pasture and Grazing	231 mi^2	2%
Other	6,249 mi^2	66%
Total Agricultural Land[2]	**12,973 mi^2**	**30%**
Other (Including Urban)	**2,261 mi^2**	**5%**
Total Land Area	39,493 mi^2	92%
Inland Waters	**3,282 mi^2**	**8%**
TOTAL AREA	**42,775 mi^2**	**100%**

CHAPTER 3 SURFACE WATER MONITORING PROGRAMS

At the core of assessing the quality of the Commonwealth's waters are the data generated from the collection and analysis of ambient surface water samples. DEQ has a long history of water quality monitoring, beginning with the first sample collected in June 1941. Over the years, the focus of monitoring has been guided by various regulatory and assessment needs. With the development and implementation of the Water Quality Monitoring Strategy in 2000, the ambient monitoring program entered a new era of statewide multilayered network monitoring that is designed to produce representative data that supports the evaluation, restoration, and protection of the quality of the Commonwealth's waters for the purposes of fishing, swimming, boating, drinking, and the propagation and growth of a balanced, healthy community of indigenous aquatic organisms. The Water Quality Monitoring Strategy was updated in 2004, 2007, and 2013 and has been formally approved by the United States Environmental Protection Agency (USEPA). [1]

To achieve this goal and satisfy scientific, legislative and aesthetic requirements related to the quality of the Commonwealth's aquatic resources, DEQ has established a series of specific objectives to identify and define the diverse functions of the Water Quality Monitoring Program:

1. Assessment and Remediation Objectives:

(**a**) Status Quo Characterizations and Assessments:

(1) Provide accurate, representative data for water quality characterization and assessment of all surface waters within the state.

(2) Establish consistent statewide siting, parameter selection and monitoring techniques, to ensure data reliability and the comparability of data.

(3) Assure that the frequency of sampling and the total number of observations collected are sufficient to provide adequate data for scientific, statistically based and defensible assessment procedures.

(4) Assure that, whenever possible, flow rates are determined simultaneously with the collection of water quality data.

(5) Monitor, according to a plan and schedule, all substances discharged into state waters that are subject to water quality standards or are otherwise necessary to determine water quality conditions.

(6) Continually evaluate the overall success of the Commonwealth's water quality management efforts.

(**b**) Impaired Waters / Remediation:

(7) Provide data to define the cause, severity and geographic extension of impaired waters:

(8) Provide adequate data for TMDL model development and validation.

(9) Provide adequate data, by means of follow-up monitoring, to evaluate the implementation of TMDL's and other best management practices.

(**c**) Variability, Trend Assessments and Forecasts:

(10) Provide adequate data and analytical procedures for short, medium, and long-term statistical evaluation of water quality variation and trends within identifiable, geographically defined waterbodies.

2. Permit Objectives:

(11) Provide data for the calculation of permit limits for the issuance, re-issuance and/or

[1] Millennium 2000 Water Quality Monitoring Strategy, Virginia Department of Environmental Quality, October 2004.

modification of effluent discharge permits.

(12) When water quality problems are suspected, provide data to detect and document water quality impairments and/or to evaluate permit adequacy, whether permitted dischargers are in compliance with permit limits or not.

3. Efficiency Objectives:

(13) Improve the efficiency of the Monitoring Program by minimizing resource requirements and the duplication of efforts while maximizing the use of integrated data collected by state and federal agencies, public utilities, private enterprises and citizens groups for statewide water quality assessments.

(14) Increase the use of biological monitoring (e.g., benthic macroinvertebrates, fish, and/or aquatic vegetation assemblages), as well as fish tissue and sediment monitoring for specific assessments of water quality.

(15) Investigate, identify and characterize additional avenues of actual or potential water quality impairment, including ground water contribution and aerial deposition.

(16) Guarantee adequate Quality Assurance/Quality Control (QA/QC) procedures to provide precise, accurate and representative water quality data for all assessment purposes.

4. Research Objectives:

(17) Provide data to validate special stream designations and/or specific water quality criteria.

(18) Evaluate new methodologies for sampling, analyzing and assessing water quality.

(19) Provide data for other research objectives.

As a result of the implementation of the new strategy, a monitoring network of multiple programs and special studies was identified and developed to include the following programs:

WATERSHED (AW) DEQ's ambient watershed network of stations represents the largest single section of the monitoring program. Detailed information on the purpose and objectives of these stations and their selection can be found in Section III.B. of the Monitoring Strategy.

ESTUARINE PROBABILISTIC MONITORING (C2) The estuarine probabilistic monitoring program covers the tidal estuarine waters of the Chesapeake Bay, coastal Delmarva and the Back Bay / North Landing River drainages. It is designed to characterize the Commonwealth's estuarine waters. This program is also integrated into National Coastal Assessment Surveys on a rotating basis once every five years.

CHESAPEAKE BAY (CB) Chesapeake Bay Program identified in section III.E.1 of the strategy. The design of this program is through the Federal-Interstate Chesapeake Bay Program and encompasses a multi-state water quality characterization effort, http://www.deq.virginia.gov/Programs/Water/ChesapeakeBay.aspx.

CITIZEN MONITORING (CM) These stations are monitored due to specific requests from the public, usually as a result of local concerns. Notification occurs in the fourth quarter of the calendar year with sampling scheduled to begin in the next monitoring year, http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/CitizenMonitoring.aspx.

FACILITY INSPECTION (FI) Facility inspections are not specifically identified in the water quality monitoring strategy but are integral to determining compliance with discharge limits. Specific sample locations are not included in the monitoring plan but only estimated numbers of samples for the purpose of calculating annual budgets.

FRESHWATER PROBABILISTIC (FP) The freshwater probabilistic monitoring program covers the non-tidal free-flowing waters of the state. The program is designed to answer the question of what is the overall water quality of the Commonwealth for free-flowing streams: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/ProbabilisticMonitoring.aspx.

FISH TISSUE (FT) Fish tissue and sediment monitoring program conducted by central office staff, http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/FishTissueMonitoring.aspx.

MERCURY (HG) Mercury Special Study Program paid for by the responsible parties.

INCIDENT RESPONSE (IR) Incident response samples are the same as PC but are non-petroleum in origin.

POLLUTION COMPLAINTS (PC) Pollution complaints are special samples collected generally as a result of a petroleum spill.

REGIONAL BIOLOGICAL (RB) Biological monitoring program which focuses on the analysis of the benthic macroinvertebrate community as a tool to detect water quality conditions. The methodology follows the USEPA Rapid Bioassessment Protocol II. For additional information visit the biological program website at http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/BiologicalMonitoring.aspx.

RESERVOIR MONITORING (RL) Reservoir monitoring which is described in the Lake Monitoring Guidance available at http://www.deq.virginia.gov/Portals/0/DEQ/Water/Guidance/092005.pdf.

SPECIAL STUDIES (SS) Special studies are identified by individual project plans and are generally specialized intensive targeted monitoring efforts designed to answer specific hypothesis related to water quality conditions.

TMDL (TM) TMDL monitoring stations are those stations associated with the development of a TMDL and subsequent implementation plan for segments listed on the 303(d) list, http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/TMDL.aspx.

TREND (TR) Trend stations are those long term stations sited for permanent monitoring for the purpose of detecting water quality trends for a wide variety of environmentally important water quality parameters.

OBSERVED EFFECTS (OE) Those stations with insufficient data for assessing and usually are those stations with small data sets during an assessment cycle that indicate a potential problem. These stations are considered carryover stations and will be sampled until sufficient data is available to determine the water quality conditions.

Data Summary

Between January 2009 and December 2014 DEQ staff collected multiple samples at 4,205 stations. From these stations, the number of independent observations for the common field measurements was 120,309 for temperature, 96,240 for pH, and 118,910 for dissolved oxygen. These samples were analyzed for a variety of chemical constituents including nutrients, bacteria, metals, pesticides, herbicides and toxic organic compounds; over 600 different parameters were sampled.

The number of stations representing a particular type of stream segment, the types of samples collected, the parameters analyzed, and the sampling frequency all vary depending on site conditions and program emphasis. A detailed report of sample locations, matrices, parameters, and frequency is available in the Annual Monitoring Plans at

http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring.aspx.

Each basin summary, found in Chapter 4.3 of this report, lists the ambient water quality monitoring (AWQM) and biological (benthic) monitoring summary data within the basin. Summaries of the sampling data collected at each station during the reporting period are provided as an Appendix supplement to this report and can be found on the DEQ water webpage http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs.aspx.

CHAPTER 3.1 FRESHWATER BIOLOGICAL MONITORING PROGRAM

Virginia's freshwater biological monitoring program began in the 1970s to fulfill requirements of the Federal 106 Grant agreement. DEQ uses benthic macroinvertebrate communities to assess the ecological health of wadeable freshwater streams and rivers. Benthic macroinvertebrates are animals without backbones that live in or on sediment or other substrates and can be seen by the unaided eye. Benthics include crustaceans, mollusks, and immature forms of aquatic insects such as caddisfly, stonefly or mayfly nymphs.

Biological monitoring, using benthic macroinvertebrates, is an invaluable tool for evaluating the temporally integrated, overall effects of the water and sediment quality in streams and rivers. Benthic macroinvertebrate communities integrate water quality and the effects of different pollution stressors through time, providing a holistic measure of their aggregate impact. Because of their sedentary nature, macroinvertebrates are good indicators of localized conditions. Most species have a complex life cycle of approximately one year or more, and thus integrate the effects of fluctuations in water quality over time which conventional water quality surveys may miss. In essence, benthic macroinvertebrates are considered to be virtual "living recorders" of water quality conditions over time. The structure and functioning of macroinvertebrate communities are extremely sensitive. These communities may exhibit responses to water quality pollutants for which specific criteria or standards have not been defined, chemical analyses are not normally performed, or tolerance is below chemical detection limits.

DEQ's biological monitoring program examines over 150 stations annually. Reasons for bioassessments can include targeted monitoring, probabilistic monitoring, tracking local pollution events, follow-up on waters of concern identified through volunteer citizen monitoring and TMDL monitoring. Data from the biological monitoring program are used for periodic review and assessment of state waters as required by Section 305(b) of the Clean Water Act. Biological monitoring is one tool used for assessing the aquatic life designated use of state waters established in 9 VAC 25-260-10 A. that states in part, "All state waters, including wetlands, are designated for the following uses: …the propagation and growth of a balanced, indigenous population of aquatic life, including game fish, which might reasonably be expected to inhabit them…"

DEQ uses two bioassessment indices to assess the biotic integrity in non-tidal freshwater streams and rivers in Virginia. In the Coastal Plain, which is characterized by low gradient streams east of the fall line, the Virginia Coastal Plain Macroinvertebrate Index (VCPMI) methodology is used. This multimetric index was developed in 1997 by the Mid-Atlantic Coastal Streams (MACS) workgroup. The VCPMI is a multimetric bioassessment index which was calibrated for low gradient Coastal Plain streams which

exhibit different benthic macroinvertebrate communities from non-coastal stream communities.

For non-coastal streams, assessment of the benthic macroinvertebrate community is based on the Virginia Stream Condition Index (VSCI). The VSCI was developed for Virginia freshwater non-coastal streams by USEPA's contractor Tetra Tech, Inc. Using historical data collected in Virginia at reference and stressed streams from 1994-1998, Tetra Tech compared the historical data against additional data collected from 1999-2002. The VSCI is based upon recent advances in bioassessment methods contained in "*Rapid Bioassessment Protocols for Use in Wadeable Streams and Rivers, Second Edition*" (Barbour et al. 1999). The VSCI, a multimetric calculation of benthic integrity converted into a single numerical score, resulted in a single reference condition for the entire non-coastal portion of the Commonwealth against which all future benthic samples will be compared. The development of this index is considered a significant step in the advancement of the biomonitoring program to address a wide range of monitoring and assessment needs. Based on recommendations from public comment and the Academic Advisory Committee, the VSCI was validated using a spatially diverse (ecoregionally and stream size) data set free of pseudoreplication. These probabilistic data sets have allowed DEQ to narrow data gaps and test the VSCI against many classification variables and confirm with certainty, the VSCI is a good assessment tool for Virginia streams.

CHAPTER 3.2 ESTUARINE/COASTAL PROBABILISTIC MONITORING PROGRAM

Virginia's estuarine probabilistic monitoring module was initiated in the summer of 2000 with a five-year grant (CR-828544-01 – period 2000-2004) from EPA's "National Coastal Assessment (NCA) Program", formerly known as the "Coastal 2000 Initiative". This original, five-year effort was defined under the terms of a proposal titled "Monitoring the US Atlantic Coast: Assessing Virginia's Estuaries and Tidal Tributaries to the Chesapeake Bay and the Atlantic Ocean", submitted to the US-EPA in the spring of 2000. Specific field methodologies and Quality Assurance requirements of the Coastal 2000 / National Coastal Assessment Program are described in the EPA documents "National Coastal Assessment Field Operations Manual" (EPA 620/R-01/003) and "National Coastal Assessment Quality Assurance Project Plan 2001-2004" (EPA/620/R-01/002).

Purpose

The original goals of the National Coastal Assessment (Coastal 2000) Program were to:

- Assess the ecological condition of estuarine resources,
- Determine reference conditions for ecological responses/stressors, and
- Build infrastructure in EPA Regions and participating states.

Additional, more specific federal objectives were to:

- Assess the health or condition of the estuarine waters of the United States and track changes in that condition through time,
- Assess the health or condition of the estuarine waters of the various coastal states and track changes in that condition through time,
- Utilize the approach to identify reference conditions for estuarine waters in the United States, and

- Utilize existing state monitoring programs as appropriate

The geographic extent of the Estuarine/Coastal ProbMon Program is restricted to the eastern-most regions of the state. It is coordinated through the DEQ Central Office in Richmond and is carried out primarily by the Piedmont (PRO - Glen Allen) and Tidewater (TRO - Virginia Beach) Regional Offices. A few of the estuarine probabilistic sites (usually 1 or 2 sites annually) fall within the geographic jurisdiction of the Northern Regional Office (NRO) in Woodbridge.

At the state level, DEQ defined its agency goals and objectives relative to its comprehensive statewide Water Quality Monitoring (WQM) Program. Each participating DEQ region needs to complete its assigned probabilistic stations in order for DEQ to reach defensible conclusions about overall estuarine water quality from a statewide perspective.

Monitoring Design

The sampling strata for tidal tributaries have been geographically defined, by estuary size and drainage location, and a set of 50 randomly selected sampling sites are selected each year. In the past these were provided annually by the EPA/ORD Gulf Ecology Division (GED) Laboratory in Gulf Breeze, Florida (2000-2004), or the Atlantic Ecology Division (AED) Laboratory in Narragansett, Rhode Island (2005-2007) upon request. Since 2007 DEQ has performed its own site selection for the state sampling design using software provided by EPA/ORD/AED.

The two principal sampling strata in the state design consist of (1) small tidal tributaries to the Chesapeake Bay and its major tributaries and (2) tidal tributaries and embayments of the Atlantic coast and Back Bay/North Landing River (which discharge into Pamlico/Albemarle Sounds, North Carolina). The major tidal tributaries to the Chesapeake Bay (the Potomac, Rappahannock, York and James Rivers), as well as the Bay mainstem, are effectively characterized by the probabilistic monitoring of Virginia's Chesapeake Bay Program. Periodically (2000, 2005-06, and 2010), these larger waters were also included in the national survey sampling design for the purpose of integration into the standardized National Coastal Assessment (NCA) Program.

In the first year of sampling, 35 sites were selected in Virginia's portion of the Chesapeake Bay mainstem and the tidal portions of its major tributaries (Rappahannock River, York River, James River, & Elizabeth River - the tidal portions of the Potomac River mainstem are entirely in the state of Maryland). To better characterize smaller estuarine subdivisions, DEQ has in subsequent years (2001-2004) emphasized, and will continue to emphasize, minor tidal tributaries to the Chesapeake Bay, the Atlantic Ocean, and to Pamlico/Albemarle Sound by sampling at 50 sites annually. Virginia's participation in the interstate Chesapeake Bay Program already provides adequate probabilistic monitoring for the characterizations of the Chesapeake Bay mainstem and its major tidal tributaries (e.g., lower Potomac, James, York, and Rappahannock Rivers). The "weighting" of the current sampling design guarantees that each year approximately 70% of the sites (~35 stations) are selected in the Chesapeake Bay drainage and approximately 30% (~15 sites) are selected in coastal drainages. This assures that approximately 90 sites will be available to characterize the coastal estuary resource class by the end of each six-year period.

Core and Supplemental Water Quality Indicators

From 2001 through 2006, with the resources provided by EPA NCA/Coastal 2000 Grants, estuarine probabilistic stations were sampled for the complete suite of parameters described in the National Coastal Assessment QAPP cited above, as well as additional parameters utilized by the Chesapeake Bay Program. The total suite of water column parameters includes profiles of temperature, pH, DO, salinity and Photosynthetically Active Radiation (PAR), as well as samples for chlorophyll, nutrients and suspended solids measurements at near-surface, mid-depth and near-bottom. In addition, homogenized sediment samples are collected for local (DCLS) analyses of particle size and total organic carbon (TOC), as well as for metals and organic contaminant analyses and toxicity testing at EPA-contracted laboratories. A separate, 0.04 m^2 sediment sample is collected and sieved in the field for later identification of macroinvertebrate benthic infauna species to complete the "Sediment Quality Triad" (SQT) for "weight-of-evidence" ecological

evaluations and assessments. In the past, EPA Grant funds also provided for the contracting of the Fisheries Science Laboratory at the Virginia Institute of Marine Science (VIMS) for fish trawls. These trawls were used to collect fish community-structure data, epibenthic organisms, incidental fish for pathological examinations, and targeted fish species for the analyses of metals and organic contaminants in whole fish tissues. Due to resource limitations, fish sampling is only included when additional funds are available for national surveys. Beginning in the summer of 2003, DEQ started supplementing the NCA core indicators with additional sampling for bacteria (fecal coliform, *E. coli*, and enterococci) and when resources permitted for dissolved and total trace metals.

Sample handling and shipping varies with the type of sample and its final destination for analysis. All samples are collected from boats anchored at the monitoring sites and are appropriately labeled and stored on wet ice at 4° C during transport to the responsible DEQ Regional Office. Samples to be analyzed at the Virginia State laboratory (DCLS) are maintained on ice and shipped daily to Richmond by overnight courier service. Such samples are received and processed within 24 hours of collection. Analyses are completed within the holding time specified in the pertinent QAPPs and EPA analytical method descriptions, after which the resultant data is entered into the DCLS LIMS system. Analytical results are subsequently transmitted to and permanently stored in the DEQ CEDS 2000 database on a daily basis. Turnaround time from sample arrival at DCLS to receipt of analytical data varies from 48 hours to 21 days, depending upon sample type.

Sediment samples that are analyzed chemically and toxicologically by other contracted laboratories are held under refrigeration at DEQ Regional Offices and are shipped to Richmond by courier on a weekly basis. Sediment toxicity samples are united and shipped weekly via overnight air to the contracted laboratory. Sediment chemistry samples are frozen and accumulated prior to shipping to the contracted laboratory. Typically, the sediment chemistry samples are delivered in two batches, one at the midpoint and one at the end of the sampling season. Benthic infauna samples are preserved in (10%) buffered formalin as soon as they are collected and are maintained at DEQ Regional Offices until the end of the field season (late September). They are then united at the DEQ Central Office and shipped to the Benthic Ecology Laboratory at Old Dominion University (ODU). Sediment chemistry and toxicity results are generally received by the end of the calendar year. The separation, identification and enumeration of benthic taxa require more time, and results from benthic analyses performed at ODU are normally available the following spring.

When included in the program, data related to fish community structure, epibenthic invertebrates, and habitat collected by VIMS trawl sampling are immediately entered into their onboard SAS database during the process of collection. Target fish species selected for chemical tissue analyses are individually labeled and wrapped and maintained on ice during transport to the laboratory. Once there, they are frozen and maintained until the end of the field season (October). They are shipped overnight, on dry ice, to EPA/GED for storage and later transshipment. Fish pathology specimens are maintained in Dietrich's solution until the end of the field season and are subsequently shipped to EPA/GED. Fish community, epibenthic macroinvertebrate and habitat data are united into a final report which VIMS sends to DEQ soon after the end of the field season in October or early November. Turnaround time for fish tissue chemical data and fish pathology data from EPA-contracted laboratories is currently at least two years.

Frequency/Duration

As is typical of probabilistic survey programs, monitoring sites are sampled only once and new sites are randomly selected each year. Under the conditions defined by the NCA QAPP, sampling occurs during the summer months from 1 July through 30 September. This period also coincides with the sampling "window" defined for the use of the Chesapeake Bay Program's "Benthic Index of Biological Integrity" (B-IBI), which is utilized to evaluate the ecological health of the benthic community.

DEQ's Estuarine Probabilistic Monitoring Program was proposed and developed as a major component of the agency's Ambient Water Quality Monitoring Program and is fully implemented at this time. The resources formerly provided by the initial EPA Coastal 2000 Grant facilitated the implementation of the program in 2000 and terminated at the end of September 2004. A transitional National Coastal Assessment Grant provided funding at a reduced level during the 2005-2006 interim. Beginning in 2007, DEQ has continued the Estuarine ProbMon Program with a slightly reduced suite of parameters using supplemental probabilistic

monitoring funds from federal §106 grants, complimented by Chesapeake Bay and general fund resources.

Quality Assurance Measures

DEQ's field and laboratory activities adhere to QA/QC protocols specified in the National Coastal Assessment Field Operations Manual (EPA 620/R-01/003) and the National Coastal Assessment Quality Assurance Project Plan 2001-2004 (EPA/620/R-01/002), except where specific variations have been authorized by the Regional NCA QA Officer. Authorized departures include the use of submerged pumps and hoses for the collection of subsurface water samples and vacuum field-filtration of nutrient and chlorophyll samples. Both of these procedures are specifically described in the corresponding sections of the contemporary QAPP and SOPs for Virginia's Chesapeake Bay Monitoring Program.

DEQ requires that a minimum of 10% QA samples (field duplicates, field blanks, etc.) be collected at estuarine ProbMon field sites for all locally analyzed parameters. At present, one or two QA sites from among the 50 sites sampled are randomly selected annually for each of the three DEQ Regional Offices.

Data Management

Both samples and the resultant data collected within the Estuarine Probabilistic Monitoring Program follow diverse pathways. Standard procedures for the preservation, transportation and delivery of samples to the Virginia Division of Consolidated Laboratory Services (DCLS) and of sample shipment to other contracted laboratories were described above.

The data flow and data management for water and sediment samples analyzed by DCLS follow pathways and turnaround times as described for the WQM Program in general. Analytical results are quality assured by DCLS and stored in their LIMS database. Results that are complete and certified there are subsequently shipped electronically to the DEQ FTP site for upload into the CEDS 2000 database on a daily basis.

Currently, all data from locally (DCLS) analyzed samples reside in DEQ's CEDS database. All analytical results receive a QA review at DCLS, prior to shipment to the DEQ database, and another QA review by programmed algorithms (data range screenings, etc.) within the CEDS database. Data that are 'flagged' by the automated screening procedures undergo an additional evaluation by DEQ's QA Officer. Whatever questions arise concerning the location, date and time of samples arriving at DCLS, or about the accuracy of DCLS data transmitted to the CEDS database are resolved immediately via e-mail and voice communication between laboratory personnel and monitoring personnel at the DEQ Central or appropriate Regional Office.

Looking to the Future

The National Coastal Assessment Program (Coastal 2000 Initiative) was instituted by EPA's Office of Research and Development (ORD) as an experimental program in 2000. The original five-year program was so successful and so well accepted by the participating coastal states that it was transferred to EPA's Office of Water (OW) as a permanent component of its national water quality monitoring strategy. An interim two-year grant supported the program (at a reduced level) during the 2005-2006 transition. Since then, the program has received partial support via the normal § 106 federal grant process.

Beginning in the summer of 2005, portions of the national design were coordinated with and integrated into the Chesapeake Bay Program's (CBP) probabilistic benthic monitoring program. Probabilistically-collected sediment-related parameters (sediment chemistry, sediment toxicity and benthic community structure – the 'Sediment Quality Triad' or SQT) from the minor tidal tributaries will supplement CBP efforts in the major tidal tributaries and mainstem of Chesapeake Bay. Use of the SQT facilitates the characterization and aquatic life use assessment of these minor tidal tributaries, where sample sizes are generally insufficient to apply the formal statistical assessment method utilized for the Benthic Index of Biological Integrity (B-IBI) in larger Chesapeake Bay assessment units (segments).

EPA carries out national probabilistic surveys on various aquatic resource classes on a five-year rotational

basis. The last National Coastal Survey was performed in 2010. The most up-to-date NCA data can be found here: http://www.epa.gov/emap/nca/html/data/index.html.

CHAPTER 3.3 ESTUARINE BENTHIC MACROINVERTEBRATE MONITORING PROGRAM

Benthic organisms are important secondary producers, providing key linkages between primary producers (phytoplankton) and higher trophic levels (crabs, bottom feeding fish and water birds). Benthic invertebrates are among the most important components of estuarine ecosystems and may represent the largest standing stock of organic carbon in the Chesapeake Bay. Some benthic organisms, such as hard clams and soft-shell clams, are economically important. Others, such as polychaete worms and shrimp-like crustaceans, contribute significantly to the diets of economically important blue crabs and bottom-feeding juvenile and adult fish such as spot, croaker, striped bass, and white perch.

The objectives of the Chesapeake Bay Estuarine Benthic Macroinvertebrate Monitoring Program are:

1. To characterize the health of regional areas of the lower Chesapeake Bay as indicated by the structure of the benthic community.

2. To conduct trend analyses on long-term data, at fixed- point stations, to relate temporal trends in the benthic communities to changes in water and/or sediment quality. The trend analyses will be updated annually as new data are available.

3. To warn of environmental degradation by producing an historical data base that will allow annual evaluations of biotic impacts by comparing trends in status within probability-based strata and trends at fixed-point stations to changes in water and/or sediment quality.

21 fixed-point stations are sampled one time per year (September) and there is one probabilistic summer sampling per year.

CHAPTER 3.4 BEACH MONITORING PROGRAM - VIRGINIA DEPARTMENT OF HEALTH

Introduction

The "Beaches Environmental Assessment and Coastal Health (BEACH) Act" of 2000 amended Section 303 of the Federal Water Pollution Control Act (33 U.S.C. 1313) by specifying monitoring and reporting requirements for pathogens and pathogen indicators in coastal recreational waters for the purpose of protecting public health and welfare. One requirement of this Act was the publication of a list of "discrete coastal recreation waters adjacent to beaches or similar points of access that are used by the public." The resultant "National List of Beaches" [http://water.epa.gov/type/oceb/beaches/list_index.cfm] was originally published by the U.S. EPA in 2004, and most recently in 2010. A current list of the beaches monitored in Virginia is available and cited below. The requirements of the BEACH Act apply only to states and tribes that have coastal recreational waters, defined by the Clean Water Act (Section 303(c) as the "…Great Lakes and marine and estuarine coastal waters that are designated by a state or tribe for use for swimming, bathing, surfing, or similar water contact activities…"

Virginia's BEACH Monitoring Program [http://www.vdh.virginia.gov/environmental-epidemiology/beach-monitoring/] was initiated in 2002 by the Division of Environmental Epidemiology (DEE) of the Virginia Department of Health (VDH). In addition to the immediate reporting and public notification requirements relative to swimming advisories, results obtained by the VDH are communicated to DEQ for inclusion in the agency's biennial 305(b)/303(d) Water Quality Assessment Reports. The specific 305(b) assessment methodologies for using (1) swimming advisories and/or (2) the enterococci concentration data from the BEACH Monitoring Program were discussed by VDH and DEQ. The final decision on appropriate methodologies is incorporated into the 2016 Assessment Guidance Manual for the Integrated 305(b)/303(d) Report.

The BEACH Monitoring Program in Virginia is designed to provide seasonal monitoring of coastal and Chesapeake Bay beaches within the Commonwealth. A public bathing beach is defined by the Code of Virginia (1980, c.428, section 10-217, 10.1-705) as "a sandy beach located on a tidal shoreline suitable for bathing in a county, city or town and open to indefinite public use." Based on these characteristics, 47 public beaches were identified prior to December of 2003, by which time their locations were communicated to EPA for the National List of Beaches. As of July 2004, these beaches were being monitored by the BEACH Program VDH Beach Monitoring. Currently, 46 beaches in Virginia are monitored by the BEACH Program. The rationale for identifying and enumerating individual beaches is discussed below, in the section on 'siting.' The localities participating in this program include the cities of Virginia Beach, Norfolk, Hampton, and Newport News, as well as the counties of Mathews, York, King George, Gloucester, Northampton, and Accomack.

Purpose

The purpose of the program is to monitor fecal contamination of coastal beaches in an effort to reduce the risk of swimmers contracting disease or infection. Weekly monitoring is conducted to determine if levels of fecal indicator bacteria (enterococci) meet Virginia's Water Quality Standards as described in Section 9 VAC 25-260 of the Virginia Administrative Code. The Standards are provisions of state law which consist of designated uses for the waters of the Commonwealth to protect public health or welfare, enhance the quality of water, and serve the purposes of the State Water Control Law and the Federal Clean Water Act.

Monitoring Design and Station Siting

The number of sampling stations at a beach is based on EPA guidance available at the following website: http://www.epa.gov/waterscience/beaches/grants/guidance/index.html. The rationale for siting and enumerating individual beaches is based on beach size and whether (1) it is small and is treated as a single entity for swimming advisories, or (2) if it is more extensive and individual sections may be placed

under advisory independently. In summary, the current list of responsible health districts and beaches includes:

Rappahannock Health District (Fairview Beach) - 1 beach
Peninsula Health District (Newport News, York) - 5 beaches
Hampton City Department of Health - 3 beaches
Norfolk Department of Public Health - 10 beaches
Virginia Beach - 22 beaches
Three Rivers Health District (Gloucester, Mathews) - 2 beaches
Eastern Shore Health District (Accomack, Northampton) - 3 beaches

Total = 46 beaches

Samples are taken in the middle of a typical bathing area. If the beach is short, samples are taken at a point corresponding to each lifeguard chair or one sample for every 500 meters of beach. Sample results from several sites at the same beach may be united into a single arithmetic average for comparison with the Water Quality Standard and evaluation for swimming advisories, see below. If the beach is long (more than 5 miles) samples are spread out along the entire beach (e.g., Virginia Beach, which is 24 miles long, has 22 sampling stations spaced at least one mile apart). Locations of sites are identified by coordinates of latitude and longitude and remain uniform from year to year in order to maintain a permanent, long-term database on beach water quality.

The most updated information relative to the BEACH Monitoring Program, including maps of sampling sites, historical results, and swimming advisories, may be found on the VDH BEACH Monitoring website. [http://www.vdh.virginia.gov/environmental-epidemiology/beach-monitoring/]. Beach monitoring and notification results are exported from the Beach Monitoring and Notification (BMAN) database weekly during the season and posted to the website Monitoring And Advisory Data By Year. Data for prior years may also be reviewed on this page.

Frequency

Beaches are sampled for fecal indicator bacteria on a weekly basis from mid-May through September. When the Water Quality Standard at a specific beach is exceeded, or when the results of bacterial analysis are inconclusive, follow-up sampling is repeated as soon as possible.

Sampling

As per EPA guidance, samples are collected 0.3 meters below the surface in water knee-deep water. VDH's 2012 Quality Assurance Project Plan provides general guidelines for sampling procedures. Samples are placed on ice and are delivered to the laboratory for processing within six hours of collection.

Samples are collected on the regular monitoring day, rain or shine, unless conditions are dangerous to sampling staff. If a decision is made not to sample because a violation of the standard is expected (e.g., heavy storm drain overflow), the beach is posted with a swimming advisory. Samples are collected and transported in the same way at all sites. All samples are grab samples, using sterile bottles that are supplied by the laboratory performing analysis.

When continued exceedances of the water quality standard occur at monitoring locations, samples may be collected for microbial source tracking analysis by the Hampton Roads Sanitation District (HRSD). The results of this analysis provide an indication of the source of fecal pollution. Varying sources of fecal pollution have shown to provide different levels of health risk to water users. Also, some sources of fecal pollution can be remediated.

Duration

Beach monitoring sites are considered permanent, fixed sites of the VDH BEACH Monitoring Program. Sampling will continue as long as funding is available. As mentioned above, the sampling is conducted from mid-May through the September swimming season.

Core and Supplemental Water Quality Indicators

The fecal indicator organism used for estuarine and marine beaches are bacteria of the genus Enterococcus. Laboratory analysis of enterococci in beach water samples is conducted using EPA approved methods. Additional measurements of air and water temperature, turbidity, dissolved oxygen, pH and salinity are also taken at beach sites during each visit.

Quality Assurance

VDH's Quality Assurance Project Plan was updated and approved by EPA in November 2012. Sampling methods are based on sections 9060 and 9060B of Standard Methods for the Examination of Water and Wastewater (APHA 2012). Standard procedures for laboratory analyses of water samples for enterococci are produced by the laboratories performing the service and are also included in the Quality Assurance Project Plan.

Annual training is provided for all field personnel and their supervisors. Training consists of sample collection and handling, data management, results interpretation, operation and calibration of equipment, and current program issues, updates, and quality assurance objectives.

Data Management

VDH receives weekly results from laboratories by email, fax, and/or conventional mail. Timely data submission is emphasized so that the VDH BEACH Monitoring website can be updated as soon as results are available. Timely data submission is mostly critical when exceedances of the Water Quality Standard occur and swimming advisories need to be issued. Upon receipt of results, VDH local health district staff enters laboratory results into a VDH database. When results are entered, swimming advisories are posted on VDH's Beach Advisory Map and Twitter (@VDHBeach) for public notification.

Data are periodically sent to EPA, via CDX for STORET, in an XML schema utilizing formats specified in EPA's Beach Monitoring Data User Guide.

Data Analysis/Assessment

Swimming Advisories: VDH compares beach water sample results with Virginia's Water Quality Standard for enterococci. The results from several simultaneously collected samples at the same beach may be united into a single arithmetic average for comparison with the Standard, and for subsequent evaluation for issuing swimming advisories. The Single Sample Maximum for enterococci is 104 colony forming units (cfu)/100ml. Samples above this level are in violation of the Virginia Water Quality Standards. One sample exceedance of the Single Sample Maximum standard is sufficient to issue a swimming advisory.

If there is a violation of the Standard, the beach is posted with a swimming advisory sign and procedures for contacting the locality where the beach is located are followed. A press release is issued to notify the public, and a follow-up water sample is collected and delivered to the lab as soon as possible. Procedures for this process are documented in the VDH's Quality Assurance Project Plan.

305(b)/303(d) Assessment and Reporting: The specific 305(b) assessment methodologies for using (1) swimming advisories and/or (2) the enterococci concentration data from the BEACH Monitoring Program was discussed by VDH and DEQ. As previously stated, the final decision on appropriate methodologies is incorporated into the DEQ Assessment Guidance Manual for the 2016 Integrated 305(b)/303(d) Report.

Reporting

If sample results exceed the Water Quality Standard, the beach is posted with a swimming advisory sign, the public is notified through press releases to local newspapers, and an advisory is posted on the VDH Beach Advisory Map [http://www.vdh.virginia.gov/environmental-epidemiology/beach-monitoring/swimming-advisories-and-monitored-beaches-map/] and on the @VDHBeach Twitter page.

Sample results and public notification data are submitted to EPA annually as required. Data collected by the BEACH Monitoring Program are available to DEQ for use in the agency's biennial Integrated 305(b)/303(d) Report via STORET (EPA database).

Programmatic Evaluation

VDH participates in biweekly conference calls and annual meetings with EPA to review the BEACH Monitoring Program in Virginia. The program is grant funded, and reviews of the yearly proposals, progress reports, and database submissions are mechanisms for programmatic evaluation by EPA. Within VDH, there is routine communication between the Division of Environmental Epidemiology and the participating health districts, and weekly reviews of data from each participating health district are performed by VDH's BEACH Coordinator and/or support staff.

General Support and Infrastructure Planning

The BEACH Monitoring Program is a federally funded program. Yearly budgets are prepared in advance to meet proposal submission deadlines established by EPA. Future changes in methodologies will depend upon EPA recommendations, and expansion of the current program may occur in response to the opening of new public beaches or their identification by local health districts.

CHAPTER 3.5 CITIZEN AND NON-AGENCY WATER QUALITY MONITORING PROGRAM

Citizen water quality monitoring has been a stewardship activity in Virginia for many years. As both the volume and quality of water monitoring data collected by entities other than the Virginia Department of Environmental Quality (DEQ) has increased, so has the desire by many of these 'non-agency' organizations for DEQ to use submitted data for more than background information in Virginia's water quality assessments. Since 1999, the agency has encouraged citizen water quality monitoring by providing technical and, whenever possible, financial support. In addition to support for citizen monitoring, the agency has been actively attempting to expand our partnerships with an increasing number of other water quality monitoring programs that operate independently of DEQ. It is important to note that while efforts are being made to utilize more non-DEQ monitoring data in assessing the quality of Virginia's surface water resources, this type of data cannot be used as evidence in any enforcement action, per a limitation in Virginia Code (§ 62.1-44.19:11).

Starting with the 2004 water quality assessment report, DEQ began using chemical monitoring data collected by citizen groups and other non-agency sources provided such data met DEQ Quality Assurance and Quality Control (QA/QC) protocols for determination of attainment of Water Quality Standards. This QA/QC process confirms whether citizen organizations and other non-agency data sources are using the same or similar sampling and testing methods that DEQ uses, ensuring that comparable data are used in any applications that include data from these sources.

In August 2004 DEQ created the Water Quality Data Liaison staff position. The purpose of the position is to provide guidance and technical support to citizen monitoring organizations, facilitate communication among citizen and non-agency water monitoring organizations, promote establishing new monitoring groups, and increase the amount and improve the quality of data shared with DEQ.

Since the 2004 water quality assessment report the amount of water quality data submitted to the agency has increased. This can be seen in the table below. The table compares the number of non-DEQ monitored sites to what the agency monitors during the previous three assessment cycles.

Quality Assurance

Currently, DEQ has contacts with over 200 citizen and other monitoring organizations. During this assessment cycle, the agency received data from over 75 organizations. The vast majority of data used in this report was collected under documented protocols, standard operating procedures, and QA/QC methods as approved or recognized by DEQ for water quality assessment. Data collected using unconfirmed protocols or where sampling occurred on waters not publically accessible such as on privately owned lakes were not used in this assessment. However such data may be useful to DEQ, and other agencies, to help prioritize future monitoring and restoration work. Additional information on how submitted data was assessed is available in the 2016 Water Quality Assessment Guidance Manual: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityAssessments.aspx

In order to assist citizen water quality monitoring groups with developing their monitoring programs, the agency developed the *Virginia Citizen Water Quality Monitoring Methods Manual*. The manual provides additional guidance on acceptable QA/QC procedures and protocols. A copy of this manual is available on the DEQ website: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/CitizenMonitoring/Guidance.aspx. In addition the agency has developed additional materials for popular methods such as the Coliscan Easygel protocol and example quality assurance project plans.

As outlined in the *Virginia Citizen Water Quality Monitoring Methods Manual*, DEQ has three levels to determine the quality of citizen and other non-agency water monitoring data. These levels increase in rank from Level I to Level III based on increasing levels of DEQ approved QA/QC protocols. Definitions of each level and how groups can achieve each of them are outlined below.

Level I - **Not approved by DEQ for assessment**. There is no Quality Assurance Project Plan (QAPP) or Standard Operational Procedures (SOP) on file. Monitoring and/or laboratory analysis does not follow DEQ sampling methods or quality assurance protocols or monitor for parameters that do not have a Virginia Water Quality Standard (http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityStandards.aspx).

- Data used by DEQ to identify sites that may require DEQ to perform follow-up monitoring.
- Data used for educational or outreach purposes.
- Data can notify DEQ of significant pollution events for rapid agency response.

Level II - **Partially approved by DEQ**. May be using a monitoring method similar to DEQ protocols but not fully approved by DEQ due to difference in sampling or testing methodology. The monitoring group may have a DEQ approved QAPP and/or SOP on file.

- All uses as stated in Level I
- Used for 305(b) assessment to identify possible waters with observed effects or waters that appear to be healthy but will need DEQ monitoring data to confirm status (Category 3C or 3D).

Level III - **Approved by DEQ.** Group follows DEQ testing protocols and quality assurance. Field sampling and laboratory testing protocols are approved by DEQ or DEQ approved accrediting authority. Group possesses a DEQ approved QAPP and SOP with no deviation from DEQ approved standardized methods (EPA methods, Standard Methods, etc.). Finally, the group must provide calibration and quality

control associated information to DEQ when submitting data. This information must meet the specific criteria stated in the QAPP.

- All uses as stated in Level II

- DEQ views this level of data as if DEQ had collected and analyzed the sample. Data that meets Level III criteria will be used in the 305(b) water quality assessment and for 303(d) listing/delisting of impaired waters.

Citizen Monitoring

Citizens of the Commonwealth monitor streams, lakes, and estuaries for a variety of parameters depending upon the goals of their own programs. Common ambient measures include many of the following physical and chemical parameters: water temperature, pH, dissolved oxygen, nutrients (various forms of nitrogen and phosphorus), or suspended solids in the water column. Biological parameters measured by citizen monitors often include benthic macroinvertebrates, *E. coli* bacteria, or chlorophyll *a*. Many of these parameters are routinely monitored by DEQ.

The Virginia Save Our Streams Program of the Virginia Division of the Izaak Walton League of America (VA SOS) took the lead in working with DEQ and the Department of Conservation and Recreation (DCR) to develop a statewide citizen monitoring program. This started with three separate letters of agreement signed by each agency in 1998 and was furthered by a three-way agreement signed in 1999. The latest version of the agreement, signed in November 2015, includes the Alliance for the Chesapeake Bay, Virginia Citizens for Water Quality and the Virginia Water Monitoring Council in addition to the original signatories from 1999.

Citizen monitoring efforts in Virginia received an additional boost in 1999 when the Virginia General Assembly approved a budget amendment to create the Citizen Water Quality Monitoring Grant Program in order to provide general funds, when available, for citizen monitoring activities. Since 1999, the Citizen Monitoring Grant Program has provided funding to over 100 different organizations. The financial support provided by the Commonwealth via this grant program has led to an increase in the quality and quantity of citizen-collected data submitted to DEQ and has proved an effective way for DEQ to encourage citizen volunteer groups to generate DEQ-approved water quality data. The grant requires recipients to submit Quality Assurance Project Plans (QAPP) and to follow DEQ approved procedures. In return, the grant recipient receives a grant award to help cover many of the costs associated with their monitoring programs.

In 2002, the Virginia General Assembly passed legislation that established the Virginia Citizen Water Quality Monitoring Program in the Code of Virginia ((§62.1-44.19:11). This legislation was later amended in 2007 under House Bill 1859 to establish a goal for DEQ to encourage citizen volunteers to monitor 3,000 stream miles by 2010. This goal was met during the 2010 305(b)/303(d) Integrated Report where 3,499 stream and for the 2014 report, 3,642 miles were monitored by volunteers.

For the 2016 assessment report, DEQ received citizen monitoring data from 1,902 sites. None of these sites met Level I requirements for all submitted parameters, 719 sites met Level II, and 916 sites met Level III for at least one water quality parameter. Of these 1,902 Level II and III stations, 128 had either missing sample site coordinates or were located in non-assessable locations such as at permitted wastewater outfalls. This assessment cycle marks the highest ever number of total number of citizen stations sampled and Level III citizen volunteer stations included in a Virginia 305(b)/303(d) Integrated Report.

Summary of Citizen Data Submissions: For the 2016 305(b)/303(d) Integrated Water Quality Assessment Report, the following citizen monitoring organizations submitted water quality data to DEQ:

Alliance for the Chesapeake Bay	Goose Creek Association	Phi Theta Kappa
Blackwater Riverkeeper	Historic Green Springs Inc.	Poquoson Citizens for the Environment
Chesapeake Beach Civic League	Hoffler Creek Wildlife Refuge	Prince William SWCD
Chesterfield WaterTrends	Isle of Wight Ruritan Club	Randolph Macon College
Chickahominy Swamp Rats	James River Association	RappFLOW
Clean Virginia Waterways	John Marshall SWCD	Rippon Middle School
Coast Guard Auxiliary Flotilla 33	Lake Anna Civic Association	Riverine Chapter VMN
Cowpasture River Preservation Association	Lake Gaston Association	Roanoke Valley Trout Unlimited
Cubitt Creek Monitors	Lake Monticello Owners Association	Smith Mountain Lake Association
Dividing Creek Association	Leesville Lake Association	Southeast CARE Coalition
Fairview Beach Residents Association	Lewis Ginter Botanical Gardens	Southern Appalachian Mountain Stewards
Four Creeks Monitors	Loudoun Watershed Watch	Southside SWCD
Fredericksburg Area Monitors for the Environment	McClure Restoration Project	Stream Watch
Friends of Norfolk Environment	Nansemond River Preservation Alliance	Thomas Jefferson SWCD
Friends of the NF Shenandoah River	New River Conservancy	Upper Tennessee River Roundtable
Friends of the Russell Fork	Northern Neck SWCD	Virginia Aquarium and Marine Science Center
Friends of the Shenandoah River	Pebble Creek Property Owners Association	VA Save Our Streams
George Mason High School	Peninsula Chapter Virginia Master Naturalists	

The Alliance for the Chesapeake Bay submitted ambient (chemical and physical) data collected by the following affiliate organizations:

City of Richmond	James River Chapter Virginia Master Naturalists	Reedy Creek Coalition
Friends of the Rappahannock Chemical Monitoring Program	Lynchburg Area Volunteers	Riverine Chapter Virginia Master Naturalists
Green Aquia	Northern Neck Chapter Virginia Master Naturalists	

The Friends of the Shenandoah River submitted ambient (chemical and physical) data collected by the following affiliate organizations:

Augusta River Monitors	Friends of the North Fork Shenandoah River	Opequon Watershed Inc.
Friends of Page Valley	Friends of the Shenandoah River	Warren County Water Monitoring Group

The VA SOS program is the largest citizen and benthic macroinvertebrate monitoring program in Virginia. The VA SOS Modified Rocky Bottom Method protocol determines the benthic community health in higher gradient streams with riffles typical to those found in the western part of Virginia. DEQ and VA SOS consider the data submitted to be Level II because it provides general information on the overall health of

a benthic community.

In response to requests from citizens located in the eastern part of Virginia, VA SOS also developed a protocol for low gradient, freshwater, non-tidal streams. At the time of this report, DEQ has not approved the low gradient freshwater streams for QA Level II or III.

The Virginia Save Our Streams Program of the Virginia Division of the Izaak Walton League of America submitted benthic macroinvertebrate data collected by the following affiliate organizations:

Albemarle County	Friends of the Rockfish Watershed	Pedlar River Institute
Amelia County Landfill	Goose Creek Association	Pound River Watershed Coalition
Blackwater SOS	Grundy High School	Prince William SWCD
Bluestone Watershed Committee	Roanoke Valley Governor's School	Radford University Green Team
Buchanan Citizens Action Group	Headwaters Association	RappFLOW
Buckingham Citizen Action League	Holston River Water Quality Monitors	Reston Association
Clinch Coalition	Hungry Mother State Park	Rivanna Conservation Society
Clinch Valley SWCD	Independence High School	Riverine Chapter of the Virginia Master Naturalists
Cowpasture River Preservation Association	John Marshall SWCD	Roanoke Valley Monitors
Culpeper SWCD	Kittrell Stream Team	Shenandoah Valley SWCD
Dan River Basin Association	Lake Anna Civic Association	Shenandoah University
Douthat State Park	Lord Botetourt High School	Smith Mountain Lake Association
Elliott Creek Watershed Protection Council	Loudoun Watershed Watch	Southwest Virginia Community College
Emory and Henry College	Loudoun Wildlife Conservancy	StreamWatch
Environmental Education Center	Maury River Middle School	Upper James River Roundtable
Environmentally Concerned Citizens Organization	Maury River Monitors	Upper Rappahannock Watershed Stream Monitoring Program
Ferrum College Dream Stream Team	Mountain Stream Stewards	Upper Tennessee Roundtable
Franklin County Master Naturalists	Middle River Monitors	Virginia Run Home Owners Association
Friends of Accotink creek	New River SWCD	Virginia's Explore Park
Friends of the Middle River	North Cross School	Virginia Tech
Friends of the North Fork of the Shenandoah River	Northern Virginia SWCD	Virginia Master Naturalists
Friends of the North River	North Virginia Chapter of Trout Unlimited	Walker Creek Watershed Group
Friends of the Rappahannock River	Oakbrook Stewards of Creation	Warren County Chapter of the Izaak Walton League
Friends of Page Valley	Patrick County Monitors	Washington and Lee University
Friends of the Pedlar River	Patrick County SWCD	

Below is an alphabetical summary of the water quality data contributions by citizen monitoring organizations that DEQ included in this report. Additional information is available in a table at the end of this summary and in Appendix D.

The **Alliance for the Chesapeake Bay** (ACB) coordinates with affiliate organizations primarily in the eastern half of Virginia. ACB volunteers monitor a conventional suite of ambient parameters including dissolved oxygen, temperature, pH, salinity, and water clarity. Trained volunteers monitored at 81 stations and collected 2,123 samples during the six-year data window for this report. Most dissolved

oxygen, pH, and temperature data met DEQ quality assurance criteria to assess water quality conditions. Of the submitted data, 7 sample sites composed of 49 sample events were not included in this assessment report due to having an unknown station location.

The **Blackwater/Nottoway Riverkeeper Program** (BNRP) is an organization that helps educate and promote environmental stewardship in the Blackwater and Nottoway Rivers. As part of this education and stewardship effort, the BNRP conducts routine monitoring for temperature, pH, dissolved oxygen, nutrients, and *E. coli* at 12 stations in several counties in southeastern Virginia. DEQ has received data from 220 sampling events for the 2016 305(b)/303(d) Integrated Report. DEQ will use this data in the assessment to determine if follow-up monitoring is needed.

The **Chesapeake Beach Civic League** conducts routine monitoring for temperature, pH, *E. coli*, and nutrients. The volunteers monitor at 14 locations covering 286 sampling events on 5 privately owned lakes. Because the lakes are not publically accessible, the data is not included in the 305(b)/303(d) assessment report. However, DEQ has been working with the volunteers to provide an informal assessment of water quality conditions at each of the monitored lakes. This information is being used to help educate homeowners on sustainable land use practices.

Chesterfield WaterTrends is a volunteer water monitoring program coordinated by Chesterfield County Department of Environmental Engineering. Chesterfield WaterTrends maintains 57 water monitoring stations in the James River watershed and collects temperature, pH, dissolved oxygen, *E. coli* bacteria, and turbidity data. DEQ has received 1,802 sample results for the 2016 305(b)/303(d) Integrated Report. DEQ will use this data in the assessment to determine if follow-up monitoring is needed.

Chickahominy Swamp Rats is a small organization founded in response to a number of bacteria impaired waters in the Chickahominy River watershed. In 2013, the organization monitored 22 locations to gauge *E. coli* levels using the Coliscan Easygel method. The results were submitted to determine if DEQ follow-up sampling is necessary.

Clean Virginia Waterways, in partnership with Longwood University, collected 788 *E. coli* samples from 21 stations along the Appomattox River as part of the Appomattox River Water Quality Monitoring Program. Upon review of sampling and laboratory procedures, DEQ will directly assess monitored waters using the *E. coli* results.

Coast Guard Auxiliary Flotilla 33, a volunteer branch of the United States Coast Guard, conducts routine monitoring for depth, temperature, pH, dissolved oxygen, and conductivity. The group monitored 7 stations in the Chesapeake Bay during the 2016 305(b)/303(d) Integrated Report time period. DEQ will use this data to assess monitored waters.

The **Cowpasture River Preservation Association** provided data to DEQ from 20 stations during this assessment cycle. The agency determined that submitted dissolved oxygen, pH, temperature and *E. coli data* are suitable to determine if follow up sampling is needed and to gauge TMDL implementation progress. Nutrient and conductivity readings were not assessed due to lack of water quality standards and the type of monitoring equipment used.

The **Cubitt Creek Monitors** collected 70 samples for temperature and *E. coli* at 10 stations in Cubitt Creek. Submitted data will be used to determine the need for additional follow-up monitoring by DEQ.

The **Dividing Creek Association** (DCA) is an active monitoring and stewardship organization located on Dividing Creek near Kilmarnock, Virginia. For the 2016 IR, DCA submitted 1261 samples from 50 stations. By following DEQ recognized protocols, DEQ will utilize temperature, dissolved oxygen, and pH data for assessing the health of Dividing Creek.

Fairview Beach Residents Association collects *E. coli* samples using the Coliscan Easygel method. DEQ received data from 69 stations. The bacteria results will be used to determine additional monitoring locations by DEQ and help with TMDL implementation efforts.

Four Creeks Monitors collects dissolved oxygen, pH, and water temperature data using DEQ approved protocols. *E. coli* samples are collected using the Coliscan Easygel method and are used to determine if follow up sampling is needed and to track TMDL implementation progress. DEQ received data from 16 stations for inclusion in the 2016 IR.

Fredericksburg Area Monitoring for the Environment (FAME) was founded in 2014 by the Tri-County City Soil and Water Conservation District. The volunteers monitor 8 sites for *E. coli* using the Coliscan Easygel method. DEQ will use the FAME results to determine if follow up sampling is required and to track local TMDL implementation progress.

Friends of Norfolk Environment collected Enterococcus samples at 11 stations during 2010. Old Dominion University performed the analysis and the data will be used by DEQ to assess recreation related water quality standards at the monitoring locations.

Friends of the North Fork of the Shenandoah River (FNSR) are an affiliated group with the Friends of Shenandoah River. Along with the routine monitoring done under the larger Friends of Shenandoah River and Virginia Save Our Streams programs, FNSR collected 98 nutrient, *E. coli* and field parameter samples at 8 stations. Of the submitted data, 2 sample sites composed of 16 data points were not included in this assessment report due to being located within VPDES permitted mixing zones.

Friends of Russell Fork monitored 19 stations and collected 324 *E. coli* and temperature readings. The data will help DEQ determine the need for additional monitoring by DEQ in the waterbodies sampled by this group.

The **Friends of the Shenandoah River** (FOSR) monitors ambient water quality for dissolved oxygen, pH, temperature, ammonia, nitrate, and orthophosphate in the Shenandoah River subbasin. From 2009 to 2014, FOSR collected 12,050 data points from 224 stations. Of the submitted data, 79 sample sites composed of 1135 data points were not included in this assessment report due to missing site coordinates or location within VPDES permitted mixing zones. DEQ is assessing FOSR data for ammonia, dissolved oxygen, *E. coli* bacteria, pH, and temperature in sampled waterbodies. The parameter nitrate is only assessed in waters designated for drinking water in this report as nitrate only has a drinking water quality standard.

George Mason High School students collected *E. coli* samples using the Coliscan Easygel method at four stations. From the start of the monitoring in February 2009 to December 2014, the students collected 112 samples. The data will help DEQ in identifying areas for future agency sampling.

The **Goose Creek Association** (GCA) collected 221 water chemistry and *E. coli* samples at 34 stations over the course of this reporting period. GCA volunteers also collected benthic macroinvertebrate data using Virginia Save Our Streams protocols and submitted results to DEQ. DEQ will use the dissolved oxygen, pH and *E. coli* data to determine if follow-up monitoring is needed. Temperature data will be assessed to indicate if the sampling stations are showing water quality attainment or impairment.

The **Historic Green Springs, Inc.** conducted monitoring in the York River Basin for temperature, pH, nutrients, and total suspended solids. Trained volunteers monitored 7 stations in this basin during the data window for this assessment. Temperature and dissolved oxygen data meeting QA/QC requirements were used to assess water quality. Total suspended solids, nutrient, and pH data was used to determine the need for follow-up monitoring.

Hoffler Creek Wildlife Foundation volunteers collected 72 dissolved oxygen, pH, and temperature samples at one site during 2009 to 2012. Data is being used to determine the need for future follow up sampling by DEQ.

The **Isle of Wight Ruritan Club** has been conducting water quality sampling at three stations. From February 2009 to December 2014, volunteers monitored on 169 occasions at 13 stations for temperature and dissolved oxygen to assess water quality. The additional parameters monitoring including pH and *E.*

coli bacteria will be used by the agency to identity need to do follow up monitoring.

James River Association (JRA) established the James River Watch program in 2013. JRA volunteers collect weekly *E. coli* samples using the Coliscan Easygel method between Labor Day and Memorial Day to gauge recreational impacts at locations not frequently monitored by other organizations. In addition volunteers collect temperature and turbidity readings while sampling. JRA volunteers sampled at 10 locations collecting a total of 141 data points. Temperature data will be used by DEQ to assess the monitored waters, and *E. coli* results will be used to determine if follow-up sampling is required. Turbidity is not assessed due to a lack of a Virginia water quality standard.

The **John Marshall Soil and Water Conservation District** (JMSWCD) conducted 1,762 sampling events at 35 sites in Fauquier County. JMSWCD volunteers collected samples to test for *E. coli* using Coliscan and sampled for temperature, dissolved oxygen, pH, and nutrients. The purpose of monitoring was to track TMDL implementation efforts and identify sites that would benefit from BMP installation. DEQ used the Coliscan results to determine the need for follow-up monitoring.

The **Lake Anna Civic Association** collected samples on Lake Anna and its tributaries using a conventional suite of ambient parameters including dissolved oxygen, temperature, pH, *E. coli*, total phosphorus, and water clarity. Trained volunteers monitored 45 stations in this basin during the data window for this report. Of the submitted data, data from 5 stations were not assessed as they are located in VPDES permitted mixing zones. DEQ is assessing the remaining data for chlorophyll a, dissolved oxygen, pH, temperature, total phosphorous, and *E. coli* for this report.

The **Lake Gaston Association** began *E. coli* sampling using the Coliscan Easygel method in 2013. Volunteers monitored 2 locations on the Virginia side of Lake Gaston. Results will be used to determine if follow-up sampling is necessary.

The **Lake Monticello Owners Association** monitors 15 stations around Lake Monticello, a privately owned lake in the Rivanna subbasin. From May 2009 to October 2014, the volunteers collected pH, dissolved oxygen, temperature, conductivity, nutrients, *E. coli* bacteria, and water clarity data during 68 sample events. Because the monitoring is on a lake that is not considered a publicly accessible waterbody, DEQ did not assess the data as part of this 305(b)/303(d) report. However, DEQ has conducted a review of the results and is working with the association to provide guidance to modify their monitoring program and provide an informal water quality assessment of lake conditions.

The **Leesville Lake Association** (LLA) volunteers are committed to monitor and promote the environmental needs of Leesville Lake located just downstream of Smith Mountain Lake. LLA volunteers, in partnership with Liberty University, have monitored 11 stations. DEQ will assess the temperature, dissolved oxygen, *E. coli*, and pH data. In addition, DEQ will use provided *E. coli* data via the Coliscan Easygel method to determine if follow-up bacteria monitoring is necessary.

Lewis Ginter Botanical Garden established a water monitoring program in 2013 to gauge water quality as it enters and leaves the property. Monitors sampled for dissolved oxygen, temperature, and pH using electronic probes and met DEQ protocols for direct assessment. The volunteers and staff also monitored for *E. coli* using Coliscan Easygel and that data will be used to determine if follow-up sampling is required by DEQ. Finally volunteers sampled for nitrate and orthophosphate using a Hach spectrophotometer. That data was not assessed because there is no existing water quality standard. 5 sites that were sampled 80 times were not assessed because the sampling locations were in privately owned ponds.

Loudoun Watershed Watch collects *E. coli* samples using the Coliscan Easygel method and benthic macroinvertebrate results using the Virginia Save Our Stream method in the Potomac watershed. DEQ received data from 13 stations. Data will be used to determine additional monitoring locations by DEQ and help with TMDL implementation efforts.

The **McClure River Restoration Project** (MRRP) is conducting an intensive *E. coli* monitoring program in the McClure River watershed. DEQ has received data from 24 stations during the assessment cycle.

Based on reviewing sampling and laboratory protocols, DEQ will use the data to assess water quality.

Nansemond River Preservation Alliance conducts routine monitoring for temperature, dissolved oxygen, salinity, water clarity, and *E. coli* at 9 stations in the James River. DEQ has received data from 244 sampling events and will use the results to assess water quality for temperature and dissolved oxygen. Water clarity and salinity will not be assessed due to a lack of an associated water quality standard.

The **National Committee for the New River** (NCNR) began monitoring at 35 locations in the New River watershed in May of 2008. Volunteers sampled for temperature, dissolved oxygen, pH, *E. coli* bacteria, and water clarity. DEQ will use the temperature, and dissolved oxygen to assess water quality at these locations. The *E. coli* and pH results will be used to determine if follow-up monitoring is necessary due to the volunteers using the Coliscan Easygel method and field pH test kits.

The **Northern Neck Soil and Water Conservation District** uses Coliscan Easygel to detect *E. coli* at several waterbodies that have a bacteria TMDL to help identify potential sources. Monitoring began in December 2012 with 4 samples collected at 4 locations.

The **Pebble Creek Property Owners Association** collected temperature and *E. coli* samples at 4 stations in the James River. DEQ received 26 data points and will use the information to determine if follow-up monitoring is needed.

The **Peninsula Chapter Virginia Master Naturalists** monitored at 4 locations 51 times during the assessment cycle. Volunteers sampled for *E. coli* using Coliscan Easygel, water temperature, salinity and water clarity. Temperature data met DEQ quality assurance standards to be used to assess monitored waters. *E. coli* will be used to determine if follow-up sampling is required. Salinity and water clarity data were not assessed due to a lack of water quality standards for Virginia waters.

The **Phi Theta Kappa Chapter of the Blue Ridge Community College** collected pH, *E. coli*, and temperature data from two stations in 2010. Results from the 24 sample events will be used to determine the need for additional agency monitoring.

Poquoson Citizens for the Environment (PCE) has been conducting temperature, pH, and *E. coli* sampling at 26 stations since January 2009. This sampling program sampled 346 times and submitted results to DEQ. Based on the protocols used by PCE, DEQ will use the pH and temperature data to assess water quality. The *E. coli* data was collected using the Coliscan Easygel method and will therefore be used to determine if follow up monitoring is necessary.

The **Prince William Soil and Water Conservation District** collected 251 *E. coli* samples at 17 locations using the Coliscan Easygel method. The data is being used by DEQ to determine if follow-up monitoring is necessary.

Randolph Macon College located in Ashland, Virginia, has used Coliscan test kits to monitor nearby Mechumps Run. Students collected 41 *E. coli* samples at 10 sites in an effort to assist DEQ in finding areas of high *E. coli* concentrations and to track TMDL implementation efforts. Based on training and technical assistance provided by DEQ, the agency is using the data to determine if follow-up monitoring is needed.

The **Rappahannock Friends and Lovers of Our Watershed** (RappFLOW) performed 24 sample events at 12 stations and collected data for temperature and *E. coli* bacteria from April to June 2009. Upon review of calibration logs and other quality assurance materials, DEQ used the data in this assessment to determine if follow-up monitoring is needed.

Rippon Middle School collected *E. coli* samples using the Coliscan Easygel method in the Potomac/Shenandoah River. DEQ received data from 6 stations. Data will be used to determine additional monitoring locations by DEQ and help with TMDL implementation efforts.

The **Riverine Chapter of the Virginia Master Naturalists** began monitoring in March 2009. Volunteers collected 104 samples for dissolved oxygen, *E. coli*, pH, and temperature at six stations. Submitted data will be used by DEQ to determine the need for future agency sampling.

Roanoke Valley Trout Unlimited collects temperature and *E. coli* samples using the Coliscan Easygel method in the Roanoke River. DEQ received data from 10 stations. Temperature data will be used for assessment. The *E. coli* results will be used to determine the need for additional agency sampling.

The **Smith Mountain Lake Association** (SMLA) and Ferrum College have partnered for many years to monitor water quality in and around Smith Mountain Lake. Currently the organization has Level III status for temperature, dissolved oxygen, pH, *E. coli* bacteria, total phosphorous and chlorophyll a. The DEQ received 2151 data points from 162 sites. DEQ will use the submitted data to assess water quality conditions at the lake.

The **Southeast CARE Coalition** is comprised of volunteers living in Newport News. Monitors collect *E. coli* using the Coliscan method along with temperature, salinity, and water clarity. Volunteers sampled at 15 locations 117 times during this assessment cycle. DEQ will use water temperature and *E. coli* data to determine if follow-up sampling is necessary. Salinity and water clarity data were not assessed because Virginia does not have a water quality standard for these parameters.

The **Southern Appalachian Mountain Stewards** collected 305 samples at 227 locations in southwestern Virginia. Volunteers monitored for water temperature, conductivity, selenium (at 5 locations) in order to identify potential impacts of nearby coal mining operations. While the data for temperature and selenium meet Level III quality assurance criteria, the data have limited use to assess monitored waters due to only receiving one or two data points at each location.

Southside Soil and Water Conservation District located in Charlotte and Lunenburg Counties collected 762 *E. coli* samples at 21 locations using the Coliscan Easygel method. Data provided to DEQ was used to determine if follow-up monitoring is necessary under the Category 3C/3D portion of the assessment report.

StreamWatch submitted benthic macroinvertebrate data. Volunteers collected 508 samples at 121 stations located around the Rivanna subbasin. Based on a validation study performed between the StreamWatch enhanced benthic monitoring program and DEQ benthic metrics, it was determined that StreamWatch data is of equal quality to DEQ benthic monitoring protocol. DEQ will use the submitted benthic data to assess water quality.

Thomas Jefferson Soil and Water Conservation District volunteers collected 395 *E. coli* samples at 26 sites using the Coliscan Easygel method. Data provided to DEQ was used to determine if follow up monitoring is necessary under the Category 3C/3D portion of the assessment report.

The **Upper Tennessee River Roundtable** (UTRR), collected *E. coli* samples using Coliscan at several creeks located around Wise, Virginia. This project was supported through DEQ in an effort to determine potential sources and areas for restoration efforts as part of the Three Creeks TMDL IP. Volunteers collected 60 samples at four stations. Based on the training and technical assistance provided by DEQ, the agency is incorporating the data into this report to determine if follow-up monitoring is needed.

The **Virginia Aquarium and Marine Science Center** volunteers sampled at seven locations 347 times during this assessment report. Monitors sampled for common field parameters including dissolved oxygen, pH, and temperature. In addition the on-site laboratory provided analysis for *E. coli* and the inorganic forms of nitrogen. The field parameters meet DEQ criteria to directly assess monitored waters. The *E. coli* results may also be assessed but only for waters where the Virginia water quality standard specifies the parameter is appropriate for assessment.

The **Virginia Save Our Streams Program** (VA SOS) is a part of the Virginia Division of the Izaak Walton

League of America who coordinates with a number of affiliate organizations across Virginia. Trained VA SOS volunteers collecting benthic macroinvertebrate samples using the VA SOS Modified Rocky Bottom Method and submitted data from 297 stations. DEQ will use SOS data to determine if follow-up monitoring is needed.

Table 3.5-1 Citizen Monitoring Data Considered for Assessment Level II and III

Citizen Monitoring Organization	Atlantic Coast		Chesapeake Bay		Chowan		James		New		Potomac/ Shenandoah		Rappahannock		Roanoke		Tennessee		Yadkin		York		Unknown VPDES		Total

Other Non-Agency Water Quality Monitoring:

By broadening the scope of our data solicitation beyond citizen monitoring, DEQ is receiving water quality data from an expanding pool of government, private industry, and other non-citizen volunteer based monitoring organizations. The guidelines for accepting these datasets are the same as with citizen monitoring data. Each organization must show documented sample collection and testing protocols and pass routine inspections and laboratory audits by the agency. Depending on the degree of compliance with the vetting of the sampling methods and test procedures, the data can either be used directly for assessment or provide locations to establish future DEQ sampling sites.

Prior to the 2004 assessment report, DEQ received water quality monitoring data from the United States Geological Survey (USGS). The data collected by the USGS follows strict adherence to EPA sampling methods and analytical procedures that are fully approved by DEQ. In addition, the United States Forest Service (USFS) routinely submits benthic macroinvertebrate data. The benthic data collected by the USFS follow standard benthic macroinvertebrate monitoring protocols that are similar to DEQ benthic monitoring methods.

Since the 2004 report, additional agencies have begun submitting water quality data for assessment. Most of the data submitted for the 2016 assessment report comes from various federal, state, and local government agencies and select academic institutions.

For the 2016 assessment report, DEQ received data from 19 non-agency organizations which monitored at 1,055 sample sites. Zero sites met Level I requirements, 31 met Level II and 1,024 met Level III for at least one water quality parameter. Of these 1,055 Level II and III stations, 4 sites had either missing sample site coordinates or were located near non representative locations such as at permitted wastewater outfalls. This is a new record in the number of non-agency sample sites included in a Virginia 305(b)/303(d) integrated report.

The following private and government organizations submitted water quality data to DEQ:

Appalachian Electric Power	Maryland Department of the Environment	Pocahontas State Park
Appalachian Technical Services	National Park Service: Assateague Island National Seashore	Tennessee Department of Environment and Conservation
City of Norfolk Department of Utilities	National Park Service: Mid-Atlantic Monitoring Network	Tennessee Valley Authority
City of Suffolk	National Park Service: Northeast Coastal & Barrier Network	United States Forestry Service
Cumberland Resources Corporation	North Carolina Department of Natural Resources	United States Geological Survey
Department of Conservation and Recreation Beach Program	Occoquan Watershed Monitoring Laboratory	Virginia Department of Health Beach Program
James City County Stormwater Division	Page County	Virginia Trout Stream Sensitivity Survey

Below is an alphabetical summary of the water quality data from non-agency organizations that DEQ included in this report. Additional information is available in a table at the end of this summary and in Appendix D.

Appalachian Electric Power monitored ten stations in the Smith Mountain Lake as part of a study on levels of dissolved copper present in the water column resulting from algae control measures. AEP staff collected 20 samples at 10 locations from January 2009 to September 2009. DEQ will use this data to determine if copper levels are within acceptable aquatic life use criteria.

Appalachian Technical Services (ATS) is a private consultant firm hired to conduct benthic macroinvertebrate sampling in streams that receive discharges from coal mining operations. In 2011 ATS staff sampled at 155 stations in the Big Sandy and Tennessee Rivers collecting benthic macroinvertebrate samples on 266 occasions. Upon review of sample collection and identification protocols, DEQ will use the submitted data to assess aquatic life use at the sampled locations.

The **City of Norfolk Department of Utilities** monitored 18 stations in public drinking water reservoirs for temperature, pH, dissolved oxygen, conductivity and nutrients. DEQ received 841 sample events worth of water quality data and will assess for temperature, pH, dissolved oxygen, and nutrients.

The **City of Suffolk** monitored 18 stations along the lower Nansemond River for temperature, pH, *E. coli, Enterococcus,* TSS, salinity, and nutrients. DEQ received 672 sample events worth of data and will assess water quality conditions for temperature, pH, bacteria, and nutrients.

The **Cumberland Resources Corporation** collected 44 samples at 2 locations in the Big Sandy River as part of a study of impacts of coal mine discharges to local streams. These samples were to test levels of chloride and will be assessed to determine impacts to aquatic life use.

The **Department of Conservation and Recreation (DCR)** performs monthly fecal bacteria sampling at beaches located in state parks. During this assessment cycle, DCR staff collected 378 *E. coli* samples at 15 locations in the York, James, Roanoke, New and Tennessee Rivers. DEQ will assess the data to determine if bacteria levels impact recreational water quality standards.

The **James City County Stormwater Division** collected *E. coli* samples using the Coliscan Easygel method. From April 2009 to March 2010, county staff collected 140 samples at 12 locations to identify areas of high *E. coli* populations. The results were submitted to DEQ to help with TMDL IP underway in the area to identify locations that could benefit from the installation of BMP's. DEQ included submitted data in this report to determine if follow-up monitoring is necessary.

The **Maryland Department of the Environment** collected and tested 29 Enterococcus samples at one location in partnership with the National Park Service Assateague Island National Seashore. DEQ will use the data to assess recreational use conditions at the site.

The **North Carolina Department of Natural Resources** conducted monitoring at two locations at 35 occasions to monitor dissolved oxygen, pH, temperature, conductivity, fecal coliform bacteria, chlorophyll a, and nutrients. DEQ will assess temperature, dissolved oxygen, and pH. Fecal coliform, conductivity, chlorophyll a, and nutrients will not be assessed due to Virginia not having quality standards for these parameters in freshwater riverine systems.

The **National Park Service Assateague Island National Seashore** participates in a multistate monitoring program in waters surrounding Assateague Island on Virginia's Eastern Shore. Park staff collected 88 samples at 7 sites located in Virginia to test for nutrient levels, algae concentration, and field parameters. DEQ will use the nutrient and field parameter data to assess water quality conditions.

The **National Park Service Mid-Atlantic Monitoring Network** is a regional program linking the various National Parks in order to conduct environmental sampling using standardized methodologies. In Virginia, the Appomattox Courthouse National Historical Park, Booker T. Washington National Monument, Fredericksburg and Spotsylvania National Military Park, Petersburg National Battlefield Park, and Richmond National Battlefield Park have participated in this program. From June 2009 to December 2014, the parks monitored 60 stations composed of 2,138 sample events. The parks sampled for dissolved oxygen, pH, temperature, and conductivity. After reviewing the protocols, DEQ will assess water quality conditions for dissolved oxygen, pH, and temperature.

The **National Park Service Northeast Coastal & Barrier Network** monitored the Potomac, James and York Rivers for temperature, dissolved oxygen, conductivity, salinity, chlorophyll a, and water clarity. DEQ received 164 samples at 84 sites. After reviewing methodologies, DEQ will assess water quality using

temperature and dissolved oxygen. Chlorophyll a and water clarity readings are not used in assessment due to the lack of numerical water quality standards in the sampled waterbodies.

The **Occoquan Watershed Monitoring Laboratory** monitors field parameters and total phosphorous at 15 sites along the Occoquan Reservoir. Trained field and laboratory staff conducted 1,640 sample events during the six year assessment window. Based on review of field and laboratory protocols, DEQ will include the results to assess water quality at the reservoir.

Page County Department of Environmental Services conducted an intensive *E. coli* monitoring program in the Hawksbill Run watershed using Coliscan Easygel. This project was supported through DEQ to determine potential bacteria sources and areas to establish restoration projects as part of the Hawksbill Run TMDL IP. Page County staff sampled at 19 stations in Hawksbill Run collecting 181samples from January 2009 through February 2010. DEQ included submitted data in this report to determine if follow-up monitoring is needed.

The **Pocahontas State Park** staff monitored a site at Bear Creek and Twin Lakes State Parks for dissolved oxygen, temperature, pH, total phosphorous, and water clarity. DEQ assessed the submitted 83 samples worth of data to determine if follow up sampling by DEQ is needed.

The **Tennessee Department of Environment and Conservation (TDEC) Division of Water Resources** collected two samples at one location in southeastern Virginia. The TDEC staff collected temperature, pH, dissolved oxygen, and *E. coli.* The data will be included in assessment.

The **Tennessee Valley Authority** (TVA) conducted one site worth of monitoring in Virginia. The monitoring consisted of collecting 14 samples for *E. coli,* temperature, dissolved oxygen, pH, and nutrients at three sites. DEQ will use the nutrient and *E. coli* results to assess water quality. Dissolved Oxygen, pH, and temperature will be used to determine the need for follow up sampling by DEQ due to questions on the frequency and procedures used to calibrate TVA field equipment.

The **United States Forest Service** (USFS) conducts an intensive benthic macroinvertebrate study in and around the national forests in Virginia. The USFS monitored at 82 stations and collected 168 benthic macroinvertebrate samples from March 2009 to April 2014. Upon review of sampling protocols, DEQ will use the benthic macroinvertebrate data for assessing water quality.

The **United States Geological Survey** (USGS) submitted water quality data for 30 stations located in the eastern and central portions of Virginia. USGS staff collected and submitted data from 794 sample events from January 2009 to December 2014. The stations monitored many ambient water quality parameters from dissolved oxygen and pH to dissolved metals. In addition, USGS conducted continuous monitoring of dissolved oxygen, pH, and temperature at 11 stations composed of 750,685 readings during the six year window. The USGS follows standard protocols for sampling and analysis of results. USGS monitoring data identified as having a Virginia Water Quality Standard were used by DEQ to assess water quality.

The **Virginia Department of Health** (VDH) collects *E. coli* and fecal Enterococcus bacteria samples from public beaches located in the eastern half of Virginia from May to October each year. For this assessment report, VDH staff collected 5,312 bacteria samples from 47 public beaches and submitted the results to DEQ. Due to VDH using the same sampling methods and laboratory procedures used by DEQ, VDH results were used by DEQ to assess water quality.

The **Virginia Trout Stream Sensitivity Survey** is managed the University of Virginia Department of Environmental Sciences and conducts a majority of water quality testing of waterbodies that support native brook trout and with an emphasis of testing on public lands such as national parks and forests. The program collected 469 sites worth of data over 2,766 sampling events. Monitoring included water temperature, pH, conductivity, hardness and ions such as chloride. This data will be used by DEQ to determine follow up sampling is needed.

The **Wolf Creek Water Reclamation Facility** submitted water quality data collected upstream of their facility to DEQ. From January 2009 through December 2014 the staff collected 52 samples from one sample site located upstream of their facility. Submitted data included stream flow, temperature, dissolved oxygen, pH, Biochemical Oxygen Demand, nutrients, and *E. coli* bacteria. DEQ will assess water quality for temperature, pH, nutrients, and *E. coli*.

Current Efforts to Support Citizen and Non-Agency Surface Water Quality Monitoring

DEQ is committed to expanding the use of non-agency surface water quality monitoring data in future assessment reports. This is primarily due to an increasing need for additional water quality data and the growth in the sophistication in water quality monitoring by sources outside of DEQ. During the past couple of years, DEQ continued to develop new content and resources to increase the amount and quality of non-agency data available.

In response to citizen concerns raised about algae growth impacting recreation use in the Shenandoah River, DEQ has committed to developing a quantifiable, repeatable field estimation method for evaluating potential impacts of algal growth in Virginia's free flowing waters. Virginia is currently testing field methods and will develop a plan for the use of citizen monitoring data in assisting with recreational use attainment determinations.

Due to the popularity of the Coliscan Easygel method by volunteer groups, the agency developed a comprehensive guide to correctly identify *E. coli* colonies using this method. The guide is available to monitoring groups by going to www.deq.state.va.us/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/CitizenMonitoring/Guidance.aspx.

Currently, DEQ is developing a series of training videos covering popular water quality monitoring methods such as Coliscan Easygel and dissolved oxygen sampling. The goal of these videos is to provide introductory or refresher training that volunteer groups can refer to. In addition, these videos will supplement material found in the popular *Virginia Citizen Volunteer Water Quality Monitoring Program Methods Manual* available on the DEQ citizen monitoring page at www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/CitizenMonitoring.aspx

Through these new and continuing efforts, DEQ is able to utilize data that was previously unavailable or unknown to the agency. DEQ values the contributions of non-agency monitoring staff and citizen volunteers and will continue to support their monitoring efforts however possible. With assistance from these organizations, DEQ is increasing monitoring coverage in Virginia.

Additional information about DEQ's continued support of volunteer and non-agency monitoring is available at:
www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/CitizenMonitoring.aspx

CHAPTER 4 SURFACE WATER QUALITY ASSESSMENT

Virginia's waters are well-known and beloved features of the state. The New River in the southwestern region of the state is considered, despite its name, to be the oldest river in North America. The famous folk song *Oh Shenandoah* refers to the Shenandoah River that runs through northwestern Virginia. The largest river in the state—the James—is considered "America's Founding River", carrying the early Jamestown settlers. Virginia Beach is a favorite destination during the summer. The Chesapeake Bay, the largest estuary in the United States, continues to delight visitors with its natural beauty, recreational opportunities, history, and seafood. Virginia's surface waters are very important to the state's welfare, and for this reason it is crucial to characterize this resource with as much accuracy as possible.

The following chapter begins by describing how DEQ accomplishes this. Results of the 2016 assessment, broken down by region, are then provided and discussed. This chapter ends an overall "snapshot" of statewide water quality captured by DEQ's freshwater probabilistic monitoring.

CHAPTER 4.1 ASSESSMENT METHODOLOGY

Revisions to the assessment guidance manual have improved assessment methodologies, quality, and consistency. Additionally, the assessment guidance manual provides the public an opportunity to review and comment on the assessment criteria and methodologies used by DEQ to determine designated use attainment. The 2016 draft manual was public-noticed in June 2016, and DEQ received public comments on the updated draft manual through July 2016. DEQ released the final 2016 Assessment Guidance Manual in September 2016.

"Ten Percent Rule"

State and federal law requires DEQ to produce a biennial report on the condition of its waters to Virginia's citizens and the EPA. The waters are evaluated in terms of whether the appropriate designated uses are met. These primary uses are: 1) wildlife, 2) aquatic life, 3) fish consumption, 4) shellfish harvest, 5) recreation (primary and secondary contact recreation) and 6) public water supply use. There are additional sub-uses associated with the Chesapeake Bay. DEQ employs the "Percent Method" to assess conventional pollutant impacts in waters for two uses: aquatic life use and recreation use.

Previous national guidance recommended that states use an assessment method based on assumptions about the kind and frequency of data needed to support an assessment. The objective of assessment is to determine whether waters are fully supporting or impaired for the designated uses of an assessment unit (AU). A 10.5% exceedence threshold is used for determining full support or impairment for conventional parameters (i.e., dissolved oxygen, pH, and temperature). An exceedance rate that is greater than 10.5% with at least 2 exceedences is considered impaired. This percentage rule is governed by the fact that sampling is associated with unknown equipment and human error, as well as an acknowledgment that designated uses are not impacted by infrequent, short-term exceedences of water quality standards.

In recent years, DEQ has been encouraged to spread its monitoring efforts over more of the state's waters. To achieve this goal with a fixed monitoring budget, the average collection frequency changed from monthly to bimonthly (every two months). This monitoring frequency has been applied to a rotating watershed scheme with approximately 1/3 of the watersheds being monitored bimonthly for a 2-year cycle with all watersheds being monitored within 6 years. The benefit from this change is that more streams and more stream miles can be assessed. The disadvantage is that the data collected from each station are fewer (12 samples/2 years). The data set has become wide geographically but more shallow in frequency. Additional monitoring program review and possible update stems from the need for additional monitoring data for Total Maximum Daily Load (TMDL) development and implementation monitoring.

Rubric Used to Assess Support of Designated Uses

Virginia bases its water quality assessment on the ability of the waters to support the associated designated uses. Designated use support is based on the waters meeting the criteria for each use as defined in the numeric and/or narrative water quality standards. The following is a general description of the criteria used to determine the quality of the waters relating to each of the designated uses. A summary is found in Table 4.1-1. Additional information related to the degree of use support can be found at the water quality standards website: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityStandards.aspx

1. Not Assessed

Waters with no data for any uses or a single sample (conventional/bacteria parameters only) (Category 3A).

2. Insufficient Information

Waters that have a single exceedance in a small dataset (2-9 samples for conventional/bacteria parameters) are considered insufficient data (Category 3B). Additionally, waters will be classified as insufficient data (Category 3B) where professional judgment is not sufficient to determine if a designated use is met. Waters where the data are not QA/QC approved but the data review indicates potential degradation are categorized as insufficient data but having observed effects (Category 3C). Waters where the data are not QA/QC approved but the assessment results indicate acceptable water quality will be considered insufficient data with no observed effects (Category 3D). Waters that were previously categorized as fully supporting a designated use (Category 2) will default to Category 3 after two assessment cycles of no new data.

3. Fully Supporting

The following is a description of the types of data and the acceptable criteria used to assess waters as fully supporting designated uses. These waters would be placed in Category 2A or 2C unless all designated uses are fully supporting, upon which the water would be placed in Category 1.

Conventional/Bacteria Parameters:

Waters that are fully supporting their designated uses can have up to 10.5% exceedences of water quality criteria for the parameters fecal coliform, *E.coli* or enterococci bacteria (recreation use), and the conventional parameters dissolved oxygen, temperature, nutrients and pH (aquatic life use) without negatively affecting designated uses. Natural variables can cause exceedences of these criteria in the 0-10.5% range and still fully support both aquatic life and recreation designated uses. All data assessed as fully supporting must be QA/QC approved.

Numerical criteria for DO, pH and Temperature (9 VAC 25-260-50) do not apply at < 7Q10 flow. 7Q10 is the lowest flow averaged (arithmetic mean) over a period of seven consecutive days that can be statistically expected to occur once every 10 climatic years (a climatic year begins April 1 and ends March 31). Data for these parameters that are from flow conditions below 7Q10 will not be used in the Integrated Report.

Toxic Pollutants:

For toxic pollutant assessment in free-flowing streams, waters where there are two or more samples and no exceedences of aquatic life criteria within a running 3-year period, using grab samples or SPMD data, are considered fully supporting for aquatic life and wildlife use. For public water supply and human health-related criteria in other surface waters, two or more samples and no exceedences during the reporting period, using grab samples or SPMD data, are considered fully supporting for PWS and/or fish consumption use. Additional information on the details of using this approach can be found in Appendix F of the 2016 Assessment Guidance Manual.

For toxic pollutant assessment in estuarine waters, where there are several types of toxic data available, a "weight of evidence" approach is used. Additional information on the details of using this approach can be found in Appendix G of the 2016 Assessment Guidance Manual.

Fish Tissue/Sediment Contamination
Waters with two or more samples, with no exceedences of the fish or fish tissue screening values found in Appendix E-1 or E-2 or sediment screening values (SVs) found in Appendix F of the 2016 Assessment Guidance Manual, are considered fully supporting.

Biological Evaluation:
For free-flowing stream biological community assessment, data for the overall assessment period are rated as not impaired where no biological assemblage (e.g. macro-invertebrates) has been modified beyond the natural range of reference conditions based on the Virginia Stream Condition Index (VSCI) or the Virginia Coastal Plain Macroinvertebrate Index (VCPMI) methodology.

Fish Advisories:
Waters where the VDH has not issued any fish advisories or prohibitions are assessed as fully supporting the fish consumption use.

Shellfish Advisories:
Those growing areas are considered fully supporting for the shellfish consumption use where no restriction or prohibition (condemnation) on shellfish harvesting is imposed as indicated by the Department of Shellfish Sanitation (DSS) summary dated January 2015.

Beach Closures/Advisories:
Beach waters are assessed as fully supporting the recreation use when no VDH beach closures were issued and/or geometric mean exceedences occurred, based on QA/QC approved sampling data, during the assessment period.

Public Water Supply Source Closures:
If no VDH public water supply source closures were issued based on sampling data during the assessment period, waters are rated as fully supporting the public water supply use.

4. Fully Supporting but Having an Observed Effect

The following is a description of the types of data and the acceptable criteria used to assess waters as fully supporting but having an observed effect for a designated use(s). It is the intent of the agency to focus additional monitoring resources on the waters that are identified as having an observed effect, based on initial monitoring data analysis. These waters would be placed in the federal Category 2 and the Virginia sub-category 2B.

Conventional Screening Parameters:
Free-flowing waters with 1 or more exceedences for sediment and/or toxicity test are considered fully supporting but having an observed effect for aquatic life use if (Category 2B) if other aquatic life criteria are met. This designation is deemed appropriate because the causative agent(s) of toxicity of an environmental sample is rarely known.

Toxic Pollutants:
For toxic pollutant assessment in free-flowing streams, a single exceedence of aquatic life criteria (in a sample of at least two) within a 3-year period, using grab samples or SPMD data, is considered fully supporting but having an observed effect for aquatic life and wildlife. For public water supply use or human health criteria in other surface waters, a single exceedence (in a sample size of at least two) is considered fully supporting but having an observed effect for PWS and fish consumption use.

For toxic pollutant assessment in estuarine waters, where there are several types of toxic data available, a "weight of evidence" approach is used. If no additional toxic data is available, the water would be assessed the same as the free-flowing waters.

Fish Tissue/Sediment Contamination:
Waters with a single exceedence of a water quality standards-based tissue value or tissue screening value found in Appendix E-1 or E-2 from one or more fish tissue or SPMD samples, or an exceedence of a screening value for sediment found in Appendix F of the 2016 Assessment Guidance Manual, are fully supporting but having an observed effect for fish consumption and aquatic life, respectively.

Biological Evaluation:
VSCI or CPMI assessment scores below the impairment threshold but the biologist's best professional judgment has determined a lack of confidence in the biological survey due to natural conditions is considered fully supporting with observed effects. If impairment was discovered from the last two samples, a documented justification for not assessing as impaired is expected. Another biological assessment should be scheduled to make a final aquatic life use determination for waters assessed as fully supporting but having an observed effect for aquatic life use.

Fish Advisories:
A VDH fish consumption advisory, where a general advisory has been issued but fish consumption is not limited, are considered fully supporting but having an observed effect. This would include the kepone advisory for the tidal James River.

Shellfish Advisories:
Those growing areas, as indicated by the DSS summary dated January 2015, that have been classified as conditionally approved (seasonal condemnations) are considered fully supporting but having an observed effect.

Beach Closures/Advisories:
One short term (less than one week in duration) beach closure and/or two short term (less than one week in duration) swimming advisories due to bacteria contamination that, based on QA/QC approved data within the 6-year assessment cycle, have a low probability that the pollution will recur (based on best professional judgment) are considered fully supporting with observed effects. Best professional judgment decisions will be based on scientific data indicating the source of the pollution causing the closure/advisory is transient and there are no plans to implement pollution reduction measures or other controls, or documentation shows that mitigation has occurred and the two most recent years of water quality data, subsequent to the mitigation, show an improvement that fully supports the designated use.

Public Water Supply Source Closure:
One short term VDH public water supply source closure during the 6-year assessment cycle with a low probability that the pollution will recur is considered fully supporting but having an observed effect. The source of the pollution is generally transient and there are no VDH plans to implement pollution reduction measures or other controls.

Other Criteria for Waters having Observed Effects
Waters for which "evaluated" data, trend analysis for parameters with no water quality standards but with screening criteria, or other water quality indicators appear to indicate an apparent effect on designated use(s) or a potential for water quality problems are considered to have "observed effects". Waters can be designated as having observed effects where there is a possible loss of a designated use documented by ancillary data such as fish kills with unknown causes and/or pollution potential documented by non-QA/QC approved non-agency studies or reports. These waters are considered insufficient data with observed effects (Category 3C). For monitoring purposes, waters with observed effects should be considered in the next regional monitoring plan for additional or continued monitoring during the next reporting period as resources allow.

5. **Pollutant Caused Impaired or Threatened Waters Not Needing a TMDL**

Impaired or threatened waters not needing a TMDL are listed in the federal Category 4. These are waters that are impaired but an EPA-approved TMDL has been developed and approved by EPA (Category 4A), waters where other pollutant control requirements are reasonably expected to result in attainment of designated use(s) (Category 4B) and waters that are naturally impaired (Category 4C).

6. Pollutant Caused Impaired or Threatened Waters Needing a TMDL

Those waters impaired or threatened by pollutant(s) and needing a TMDL are included in the 303(d) list. These waters are placed in the federal Category 5 (needing a TMDL) and the Virginia sub-categories of 5A, 5B, 5D and possibly 5C and 5E. The following is a description of the types of QA/QC-approved data and the acceptable criteria used to assess waters as impaired or threatened for the designated uses.

Conventional Parameters:

Waters with long-term or chronic pollutant-related problems based on the assessment of monitored data are considered impaired and needing a TMDL. For conventional parameters, at least two exceedences of water quality standards and exceedences >10.5% are considered impaired and needing a TMDL. Additionally, waters with one or more exceedences of a monthly geometric mean analysis are considered impaired. Geometric mean analysis is normally associated with the BEACH monitoring program conducted by VDH but also could be associated with a designed, multiple sample per month, bacteria special study.

Toxic Pollutants:

Virginia will declare waters impaired for aquatic life use and included in Category 5A if 1) an acute criterion is exceeded two or more times within a three-year period based on either grab samples or samples collected with a 30-day semi-permeable membrane device (SPMD) or if 2) a chronic criterion is exceeded two or more times within a three-year period based on either multiple grab samples collected within two separate four-day periods or multiple samples collected with a 30-day semi-permeable membrane device (SPMD). For public water supply or human health criteria in other surface waters, two or more exceedences of the same criteria within the reporting period using grab samples or SPMD data are considered impaired and needing a TMDL for PWS or fish consumption use.

For toxic pollutant assessment in estuarine waters, where there are several types of toxic data available, a “weight of evidence” approach is used.

Fish Tissue Contamination:

Waters exceeding the same toxic human health criteria-based tissue value (TV), listed in Appendix E-1 of the 2016 Assessment Guidance Manual, two or more times are impaired for fish consumption. For example, the following situations would qualify as impaired under these guidelines :1) two or more tissue samples from different fish species exceeding the same TV during one sampling event; or 2) two or more samples of the same or different species exceeding the same TV from different sampling events within the assessment period.

Biological Data:

For free-flowing waters where the biological community VSCI or CPMI survey data are confirmed to be moderately or severely impaired, are considered impaired and needing a TMDL. Based on professional judgment and/or other supplemental data, a second survey may be required to confirm moderate impairment and pollutant related causes. In this case, the initial assessment would be considered fully supporting but having an observed effect and follow-up monitoring scheduled.

Fish Advisories:

Virginia Department of Health (VDH) fish consumption prohibitions and/or advisories, where fish consumption is specifically limited, are considered evidence of non-attainment of the designated use and are therefore considered impaired and needing a TMDL.

Shellfish Advisories:

Those growing areas, as indicated by the DSS summary dated January 2015 that have been classified as prohibited or restricted (condemnations) based on bacteria data are considered impaired and needing a TMDL. Restricted areas that have been administratively condemned due solely to the presence of a VPDES permitted outfall or administrative closure where no data is available will not be assessed as the shellfish use has been administratively removed.

Beach Closures/Advisories:
One or more geometric mean exceedences, one or more beach closures of one week or more duration, or two or more swimming advisories of one week or more duration due to bacteria contamination, and, based on QA/QC approved data within the assessment cycle, there is a medium to high probability that the closure/advisory will recur (based on best professional judgment) are considered evidence of impaired recreation use and a TMDL is needed.

Public Water Supply Source Closure:
One or more VDH public water supply source closures within the assessment cycle with a medium to high probability that the pollution will recur indicate non-attainment and a TMDL is needed. There are plans to implement pollution reduction measures or controls.

Chesapeake Bay Aquatic Life
See Chapter 4.5 of this report, or Section 6.4 of the 2016 Assessment Guidance Manual.

Table 4.1-1 Summary of the designated use assessment methodology

Designated Use	Parameter/Data Type	Fully Supporting	Observed Effects (either as supporting or with insufficient data)	Impaired
Aquatic Life **Wildlife (toxics only)**	Conventional[1]	• n ≥ 2, exceedence rate ≤ 10.5% for field parameters • Median lacustrine TP[2] below criterion • 90th percentile lacustrine chlorophyll a below criterion	• Evaluated[3] data with an exceedence rate > 10.5% • Single exceedence in small dataset (n <10)	• n ≥ 2, exceedence rate > 10.5% for field parameters • Two exceedences in small dataset • Median lacustrine TP above criterion • 90th percentile lacustrine chlorophyll a above criterion
	Biological	Benthic index scores ≥ impairment threshold	• Evaluated[3] data suggest degraded community • Benthic index score conflicts with biologist's best professional judgment	Benthic index score < impairment threshold
	Toxics	n ≥ 2, no exceedences	• Single water column grab or SPMD[4] sample exceedence of acute aquatic life use criteria • Single water column grab or SPMD sample exceedence of chronic aquatic life use criteria in a 3-year period • Single sediment toxicity test or screening value exceedence (aquatic life only)	Two or more grab or SPMD exceedences of the same acute aquatic life criteria in a 3-year period Two or more exceedances of the same chronic criteria within a 3-year period based on multiple grab samples within two separate four-day periods, or two or more separate 30-day SPMD deployments.

Designated Use	Parameter/Data Type	Fully Supporting	Observed Effects (either as supporting or with insufficient data)	Impaired
Recreation	Bacteria	• No geometric mean exceedence • n ≥ 2, exceedence rate ≤ 10.5%	• Evaluated[3] data with exceedence rate > 10.5% • Single exceedence in small dataset (n <10)	• One or more geometric mean exceedences • n ≥ 2, exceedence rate > 10.5% • Two exceedences in small dataset
	VDH notice	No swimming advisory	A single short-term (< 1 week) VDH closure/advisory with low probability of recurrence, based on bacteria data	One or more closure(s) and/or two or more advisories > 1 week duration with medium or high probability of recurrence, based on bacteria data
Shellfishing	VDH notice	Approved shellfish harvest waters	Area classified as "conditionally approved"	Areas classified as "restricted" or "prohibited"—excluding VPDES[5] outfalls and administrations closures where no data are available
Fish Consumption	Toxics	No exceedences of fish tissue criteria	• Single exceedence of a human health criterion using grab sample or SPMD data • Single exceedence of a tissue value or tissue screening value	• Two or more exceedences of a human health criterion using grab sample or SPMD data • Two or more exceedences of a tissue value
	VDH notice	No advisories	A VDH advisory which does not limit consumption is in effect	A VDH advisory or restriction limiting or prohibiting consumption
Public Water Supply	Toxics	n ≥ 2, no exceedences	A single exceedence of human health criteria using grab or SPMD data	Two or more exceedences of the same human health criteria using grab samples or SPMD data
	VDH notice	No closures	A single VDH closure with low probability of recurrence	One or more closure with medium or high probability of recurrence

[1]Refer to 2016 Assessment Guidance Manual for assessment methodology specific to continuous monitoring data and Chesapeake Bay criteria.
[2]TP = total phosphorus concentration. Along with lacustrine chlorophyll a, *only data from the most recent two years are aggregated.*
[3]Evaluated data are any Level II data submitted to DEQ. See Chapter 3.5 for more information.
[4]SPMD = semi-permeable membrane device (an instrument that passively samples ambient toxics over some length of time)
[5]VPDES=Virginia Pollution Discharge Elimination System

EPA ASSESSMENT CATEGORIES and VIRGINIA SUBCATEGORIES

FULLY SUPPORTING - Waters are supporting one or more designated uses

- **EPA Category 1 -** Attaining all associated designated uses and no designated use is threatened

  Va Category 1A - waters are attaining all uses and a TMDL has been developed for one or more uses.

- **EPA Category 2 –** Available data and/or other information indicate that some, but not all of the designated uses are supported.

  Va. Category 2A - waters are supporting all of the uses for which they are monitored.

Va. Category 2B - waters are of concern to the state but no water quality standard exists for a specific pollutant, or the water exceeds a state screening value or toxicity test.

Va. Category 2C - waters are now attaining the use(s) for which they were originally 303(d) listed and the TMDL is EPA approved but other applicable use(s) were not monitored and assessed.

INDETERMINATE - Waters needing additional information

- **EPA Category 3 -** Insufficient data and/or information to determine whether any designated uses are met.

Va. Category 3A - no data are available within the data window of the current assessment to determine if any designated use is attained and the water was not previously listed as impaired.

Va. Category 3B - some data exists but it is insufficient to determine support of any designated uses. Such waters will be prioritized for follow up monitoring.

Va. Category 3C- data collected by a citizen monitoring or other organization indicate water quality problems may exist but the methodology and/or data quality has not been approved for a determination of support of designated use(s). These waters are considered as having insufficient data with observed effects. Such waters will be prioritized by DEQ for follow up monitoring.

Va. Category 3D - data collected by a citizen monitoring or other organization indicate designated use(s) are being attained but the methodology and/or data quality has not been approved for such a determination.

IMPAIRED - Waters are impaired or threatened but a TMDL is not required

- **EPA Category 4A -** water is impaired or threatened for one or more designated uses but does not require a TMDL because the TMDL for specific pollutant(s) is complete and US EPA approved.

- **EPA Category 4B -** water is impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements (such as VPDES limits under a compliance schedule) are reasonably expected to result in attainment of the water quality standard by the next reporting period or permit cycle.

- **EPA Category 4C -** water is impaired or threatened for one or more designated uses but does not require a TMDL because the impairment is not caused by a pollutant and/or is determined to be caused by natural conditions.

Va. Category 4D - part(s) of a water quality standard is attained for a pollutant with a TMDL, but the remaining criteria for the standard were not assessed due to insufficient information. (Only to be applied to dissolved oxygen in tidal waters of the Chesapeake Bay).

IMPAIRED - Waters are impaired or threatened and require a TMDL

- **EPA Category 5 - Waters are impaired or threatened and a TMDL is needed.**

Va. Category 5A - a water quality standard is not attained. The water is impaired or threatened for one or more designated uses by a pollutant(s) and requires a TMDL (303d list).

Va. Category 5B - the water quality standard for shellfish use is not attained. One or more pollutants causing impairment require TMDL development.

Va. Category 5C - the water quality standard is not attained due to "suspected" natural conditions. The water is impaired for one or more designated uses by a pollutant(s) and may require a TMDL (303d list). Water quality standards for these waters may be re-evaluated due to the presence of natural conditions.

Va. Category 5D - a water quality standard is not attained where TMDLs for a pollutant(s) have been developed, but one or more pollutants are still causing impairment requiring additional TMDL development.

Va. Category 5E - effluent-limited waters receiving discharges from facilities not expected to meet compliance schedules by next permit cycle or reporting period.

Va. Category 5F - the water quality standard is attained for a pollutant(s) with a TMDL and 303(d) delisting approved, but the water remains impaired for additional pollutant(s) requiring TMDL development.

Va. Category 5R - the Water Quality Standard is not attained and the water is impaired, and implementation of an EPA-approved restoration plan is expected to result in attainment. A status update will be provided each 303(d) cycle to evaluate progress.

- **EPA Category 5M** - waters impaired due to atmospheric mercury.

CHAPTER 4.2 WATER QUALITY ASSESSMENT SUMMARY

The overall water quality for Virginia is assessed based on whether the condition of the waterbody being assessed allows citizens to safely enjoy its designated uses as described in Virginia's water quality standards. Table 4.2-1 briefly describes the primary designated uses and the parameters used in this assessment to demonstrate their attainment. Several additional aquatic life sub-uses have been adopted for the Chesapeake Bay and the tidal tributaries. Additional information about the Bay sub-uses can be found in Chapter 4.6.

Table 4.2-1 Designated use descriptions and indicators

DESIGNATED USE	USE DESCRIPTION/INDICATORS
Aquatic Life Use, Chesapeake Bay sub-uses	Description: The propagation, growth, and protection of a balanced indigenous population of aquatic life that may be expected to inhabit a waterbody
	Indicators: Dissolved oxygen, pH, temperature, chlorophyll a, nutrients, water column and sediment toxics, toxicity tests, benthics, submerged aquatic vegetation
Fish Consumption Use	Description: Game and marketable fish species that are safe for human health
	Indicators: VDH notices, fish tissue toxics, water column toxics
Shellfishing Use	Description: Marketable shellfish (clams, oysters, mussels) that are safe for human health
	Indicators: VDH notices
Recreation (Swimming) Use	Description: Swimming, boating, and other recreational activities
	Indicators: VDH notices, bacteria
Public Water Supply Use	Description: Drinking water safe for human health
	Indicators: VDH notices, water column toxics
Wildlife Use	Description: The propagation, growth, and protection of associated wildlife
	Indicators: Water column toxics

The six-year assessment begins with an analysis of all quality assurance/quality control (QA/QC) approved data from DEQ ambient water quality, biological, sediment and fish tissue monitoring, special studies and/or other non-DEQ water quality data, including citizen monitoring data. Non-agency monitoring data is evaluated for use in the assessment using a process outlined in Part VI, Section 6.3.1 of the 2016 Assessment Guidance Manual. The results of these comprehensive data analyses are compared to both numeric and narrative criteria related to the designated uses established by Virginia's water quality standards, which are provisions of state and/or federal regulations. A description of the assessment methodology can be found in Chapter 4.1, as well as the 2016 Assessment Guidance Manual.

Statewide summaries of the river miles, estuarine square miles, and lake/reservoir acres within and bordering Virginia are presented in Tables 4.2-2 through 4.2-4. The overall assessment of each waterbody was determined by examining the support of up to six designated uses (see Figure 4.2-1), as appropriate, for each assessed waterbody. The assessment of a specific use depends on the types of data that are available. Additionally, not all uses may exist in a given water. For instance, the public water supply use only applies to the waters designated in Virginia's water quality standards. The shellfishing use only exists in estuarine waters.

Additional geographical re-indexing and use of the National Hydrologic Database (NHD) has altered the actual number of stream miles within the state from previous reports. The stream mile delineation guidance has provided basic guidelines to the regional assessment staff for associating the mileage assessed, relative to a specific sampling station. This is especially important where there are no easily identifiable changes in watershed characteristics. In some cases, the stream miles associated with a sampling station have been conservatively reduced or in other cases, slightly expanded from previous assessment reports. In many cases, additional monitoring stations have been added in the watershed and may increase the size of some impaired segments depending on the additional data collected and assessed. The stream mile delineations found in this report are only reflective of the 2016 assessment period but follow closely with the monitoring efforts reported in previous reports.

A total of 100,974 miles of rivers, 2,848 square miles of estuarine waters, and 117,215 acres of reservoir/lakes was determined to be available for assessment this cycle. This increase reflects the on-going refinement to DEQ's Geographic Information System (GIS) tools.

Table 4.2-2 Assessment Results for Rivers

Degree of Use Support	**Water Type**	**Total Miles** ***(Rounded to the Nearest Whole Number)***	**(%) Total**
Fully Support All Designated Uses **(EPA Category 1)**	River (mi.)	**34**	0.0%
Virginia Subcategory 1A		20	
Fully Support Some Uses but Insufficient Data to Assess All Uses **(EPA Category 2)**	River (mi.)	**7,082**	7%
Virginia Subcategory 2A		4,514	
Virginia Subcategory 2B		2,365	
Virginia Subcategory 2C		203	
Insufficient Data to Determine if any Uses are Being Met **(EPA Category 3)**	River (mi.)	**78,576**[1]	77.8%
Virginia Subcategory 3A		76,223	
Virginia Subcategory 3B		542	
Virginia Subcategory 3C		541	
Virginia Subcategory 3D		1,270	
Waters are Impaired or Threatened but do not need a TMDL **(EPA Category 4)***	River (mi.)	**6,924**	6.9%
EPA Subcategory 4A		6,695	
EPA Subcategory 4B		0	
EPA Subcategory 4C		228	
Waters are Impaired or Threatened and need a TMDL **(EPA Category 5)***	River (mi.)	**8,358**	8.3%

1 The conversion to the higher resolution (1:24,000) National Hydrography Dataset (NHD) resulted in a significant increase in stream mileage, and, consequently, a higher percentage of waters considered "not assessed" due to the inclusion of previously unmapped waterways—mostly small unnamed tributaries. DEQ's freshwater probabilistic monitoring program, described in chapter 4.4, includes coverage of small unnamed tributaries as part of the randomly generated station locations. Prob Mon data is used to answer questions about statewide and regional water quality conditions, and to identify problem areas for follow-up monitoring.

Degree of Use Support	Water Type	Total Miles *(Rounded to the Nearest Whole Number)*	(%) Total
Virginia Subcategory 5A		5,459	
Virginia Subcategory 5B		0	
Virginia Subcategory 5C		406	
Virginia Subcategory 5D		2,410	
Virginia Subcategory 5E		0	
Virginia Subcategory 5F		84	
Total Size	River (mi.)	**100,974**	100%

* Assessment Unit VAS-Q08R_PLR01A08 – Poplar Creek (3.03 miles) is incorrectly counted as Category 4A in the table. The aquatic life use benthic impairment could not be nested into an existing TMDL due to the lack of supporting water quality data and should remain as Category 5A. The overall Category for the Assessment Unit should be 5D.

Table 4.2-3 Assessment Results for Lakes/Reservoirs

Degree of Use Support	Water Type	Total Acres *(Rounded to the Nearest Whole Number)*	(%) Total
Fully Support All Designated Uses **(EPA Category 1)**	Lakes (acres)	**12**	0.0%
Virginia Subcategory 1A		0

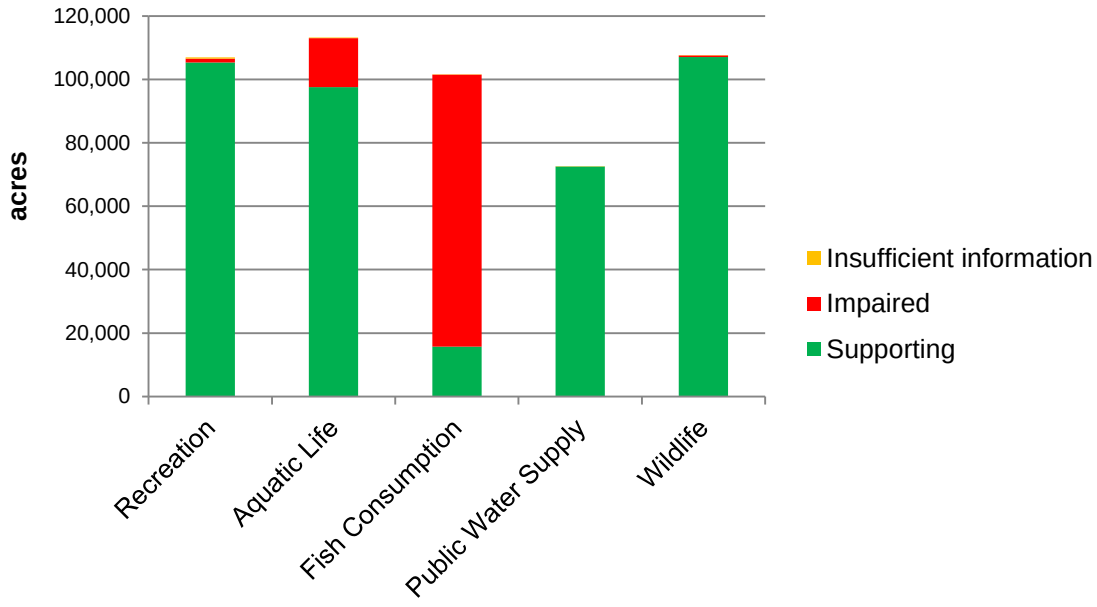

Figure 4.2-1 Designated use support summary. (Note: Waters that have some data, but not enough to determine use support, are classified as having "Insufficient information")

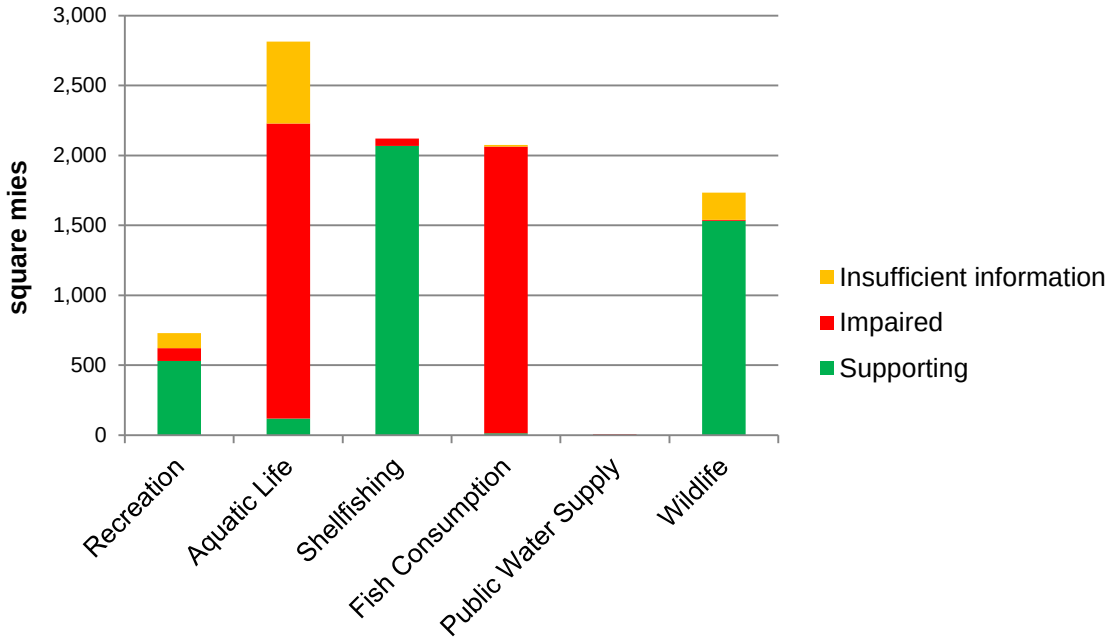
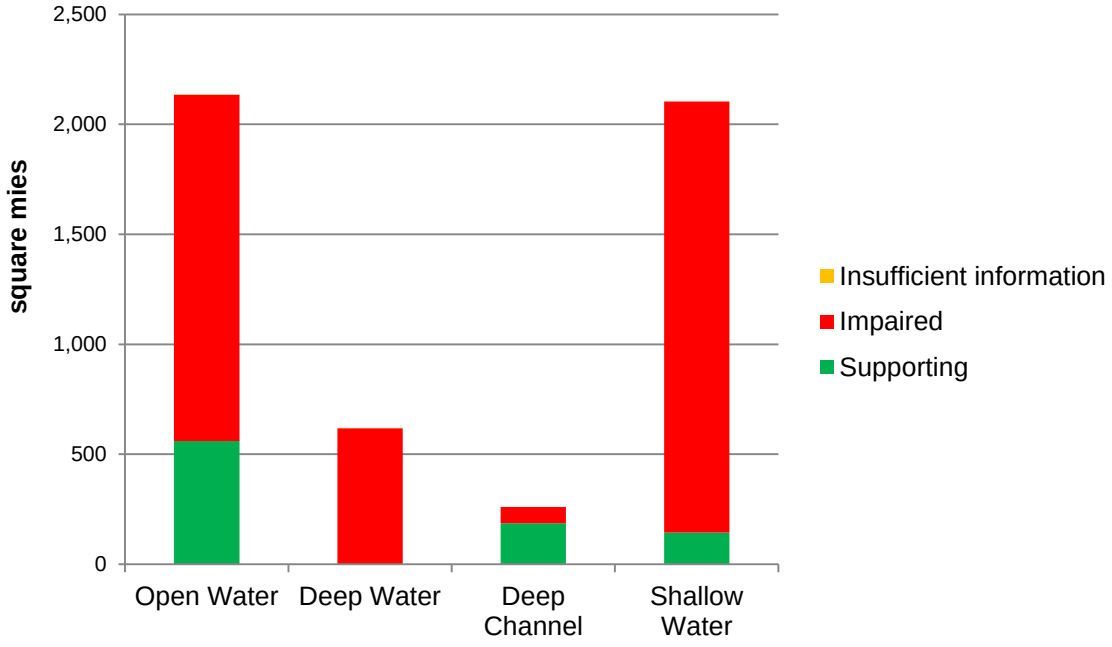
Size: ***All Sizes Rounded to the Nearest Whole Number***
Rivers - 100,974 miles
Lakes - 117,215 acres
Estuaries - 2,848 sq. miles



a) Rivers Assessment (78,576 miles were not assessed)



b) Lakes Assessment (3,373 acres were not assessed)

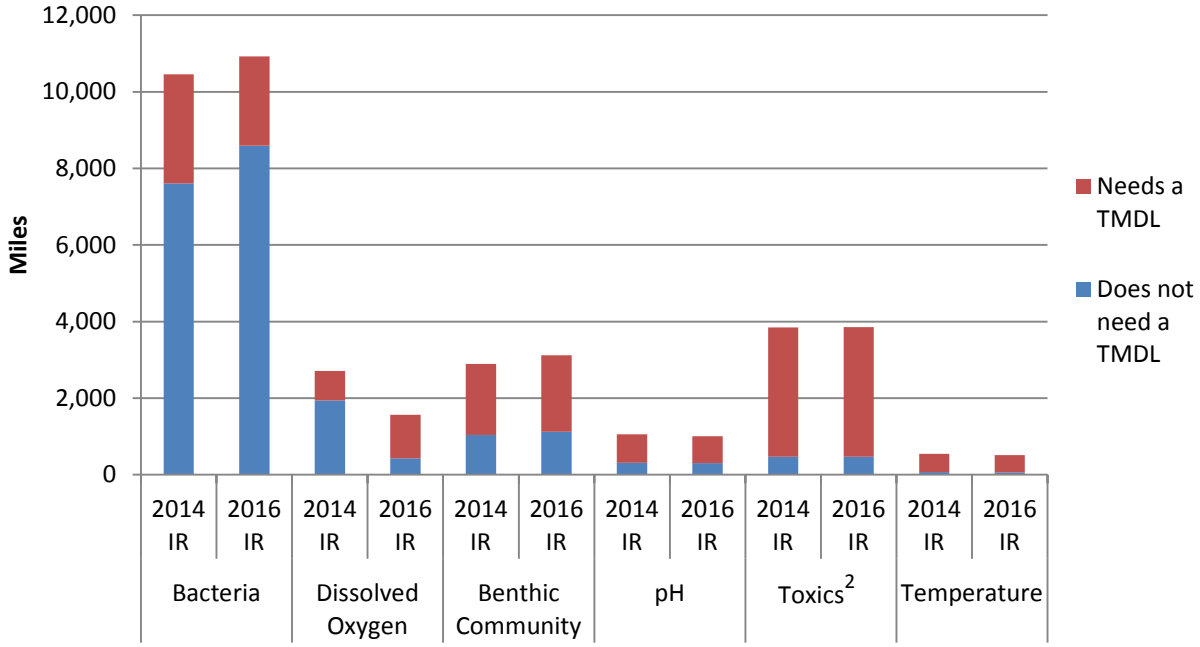
c) Estuaries assessment (400 sq miles were not assessed)

d) Assessment of Chesapeake Bay-specific designated uses (Migratory fish spawning and nursery use was not assessed.

Results

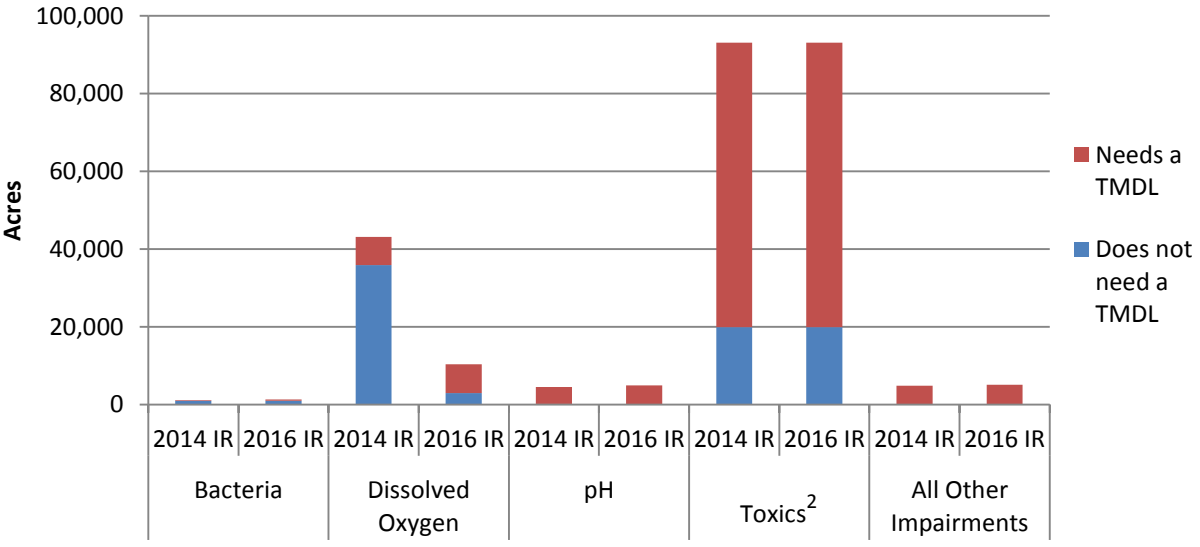
Figure 4.2-2 and Table 4.2-5 lists the major causes and sources of impairment for those waters not attaining full support for at least one designated use. Impairment causes and/or sources can be a "major impact", defined as that which causes a significant impairment to the waterbody, or moderate and minor impacts individually or in combination. Normally a major impact would be from a sole source with a large pollutant(s) contribution. Moderate and/or minor impacts have a slight to moderate effect on the waters and may be from a single moderate contributor or a combination of several minor contributors. It is important to note that moderate and minor impacts can, under certain conditions, work in conjunction to cause a major impact. Assessors take into consideration such factors as land use and co-occurring impairments when determining likely sources of pollution for a particular water.

One major cause of impairment of the aquatic life use is low dissolved oxygen concentration. All aquatic life depends on oxygen, and when it is depleted to the point where aquatic life is no longer sustainable, a water is said to be hypoxic. Hypoxia can result from natural processes, such as in slow-moving swamp waters that have large amounts of decaying plant material. It can also naturally occur in lakes/reservoirs when the water column becomes thermally stratified. However, chronic hypoxia often occurs for anthropogenic reasons. Nutrient pollution can cause hypoxia by promoting the growth of algae blooms. Excessive algae produce floating mats on the water surface which keep light from reaching rooted vegetation, therefore limiting its growth. Moreover, as algae die and settle to the bottom, decay processes reduce oxygen levels and create unfavorable conditions for other aquatic organisms. Fish kills often result from hypoxic conditions. Stormwater runoff, which often carries lawn/agricultural fertilizers and nutrient-rich animal wastes, is a major contributor of nitrogen and phosphorus pollution.



The major cause of impairment of the recreation and shellfishing uses is excessive bacteria. *Escherichia coli* (*E. coli*) is the pathogenic indicator used in freshwater, while enterococci is used in estuarine/coastal waters. These bacteria are associated with the fecal matter of warm-blooded animals. Bacteria and other microorganisms are found naturally in water, but can become harmful to human health in high concentrations. Exposure to water-borne pathogens can cause various gastrointestinal, skin, neurological, and other serious diseases. Stormwater runoff often carries domestic and livestock animal wastes, and it is a major source of impairment. Inadequate sewerage and combined sewer overflows are other major sources.

Mercury and polychlorinated biphenyls (PCBs) are the major causes of impairment of the fish consumption and public water supply uses. Mercury, specifically in the form of methylmercury, causes damage to the human central nervous system and brain. The metal can be found naturally, but its appearance in the environment is often due to anthropogenic reasons. Mercury commonly enters water through atmospheric deposition. Air particles can travel vast distances, so locating a single source is not possible in most cases. Some anthropogenic sources of atmospheric mercury are coal combustion, waste incineration, and metal processing. PCBs are another common cause of impairment. While the toxicity of individual PCBs depends on the specific form (or congener), this class of organic compounds contains endocrine disruptors, neurotoxins, and carcinogens. Like methylmercury, PCBs accumulate in fish tissues. The production of PCBs, used mainly as coolants and insulating fluids, was banned in the US in the late 1970s. However, PCBs are still quite ubiquitous, frequently appearing as "legacy contaminants" in soils close to where dischargers once used PCBs in industrial processes. These soils can then enter nearby water sources through stormwater runoff.



As evident in Figure 4.2-2, below, the Commonwealth has made significant progress on completing TMDL plans for many impairments, including bacteria, benthics, and dissolved oxygen, while other impairments, such as toxics in fish tissue, still require a TMDL. DEQ currently has TMDL projects underway to address toxics in fish tissue in the New River and lower James River basins, and is initiating a TMDL study to address toxics in fish tissue in the upper James River. Chapter 7.2 provides more information on the prioritization process for TMDL development through 2022.

Figure 4.2-2. Summary of impaired waters as reported in the 2014 and 2016 Integrated Reports. Differences between reporting periods reflect both proposed delistings and new impairment listings. Blue shading indicates the size of the waterbody that does not require a TMDL because one has been developed, other pollution controls are in place or the condition in considered natural (category 4). Red shading indicates that a TMDL is required (category 5).

a. Stream miles.

b. Acres of lakes.

[2] The overwhelming majority of toxics impairments in rivers, lakes and estuaries are due to exceedences of thresholds for PCBs and Mercury in fish tissue.

c. Square miles of estuarine waters.

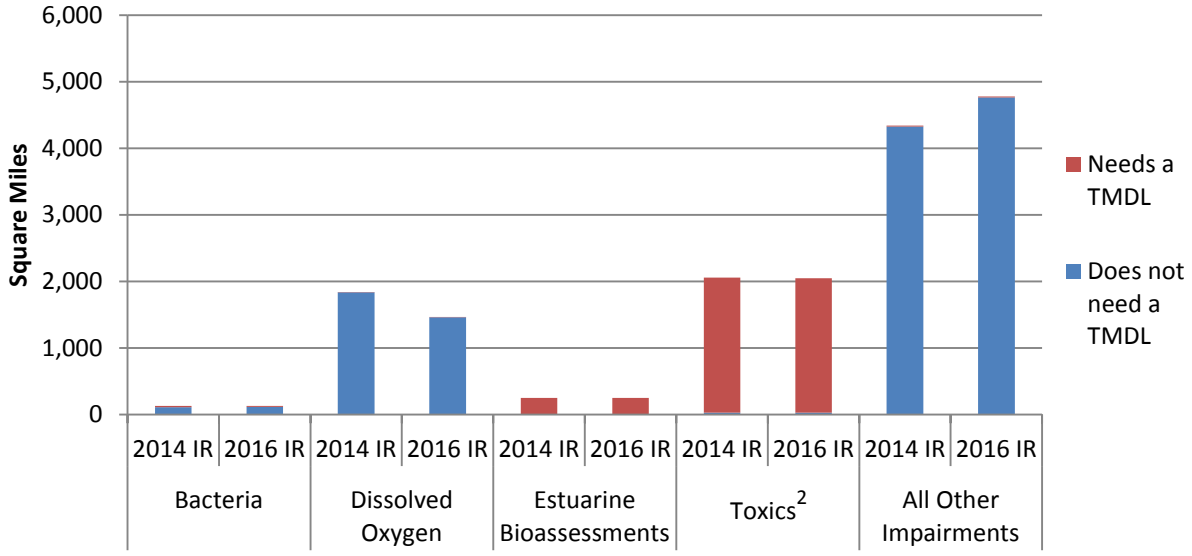


Table 4.2-5 Suspected sources of designated use impairment, by water body type, ranked by percentage of impaired water size. (Note: Waters can have multiple sources of pollution.)

CHAPTER 4.3 INDIVIDUAL RIVER BASIN DESCRIPTION AND ASSESSMENTS

Potomac and Shenandoah River Basin

The Potomac-Shenandoah River basin, as its name implies, is made up of the Shenandoah River sub-basin and the Potomac River sub-basin. It occupies the northern portion of Virginia and covers 5,681 square miles or 13% of the Commonwealth's total area.

In Virginia, the Potomac-Shenandoah basin is defined by both hydrologic and political boundaries. The James River and Rappahannock River basins bound the basin to the south. The West Virginia and Maryland State lines and the District of Columbia bound the northern and western perimeter of the basin.

The headwaters of the Shenandoah River sub-basin begin in Augusta County and flow in a northeasterly direction for approximately 100 miles to the West Virginia state line. The basin averages 30 miles in width and covers 3,384 square miles.

The topography of the Shenandoah River sub-basin is characterized by rolling hills and valleys bordered by the Appalachian Mountains to the west and the Blue Ridge Mountains to the east. The Massanutten Mountain Range divides the Shenandoah River into the North and South Forks. Tributaries of the Shenandoah River exhibit steep profiles as they drain the surrounding mountain ridge. The mainstem of the Shenandoah exhibits a moderately sloping profile with occasional riffles and pools. Approximately 45% of the land is forested due to the large amount of federally-owned land and the steep topography. Farmland and pasture account for 39% of the land area, while 16% is urban.

The Potomac River sub-basin headwaters begin in Highland County. The drainage area is 323 square miles for the headwaters. The river then flows in a northeasterly direction through West Virginia and Maryland before joining the Shenandoah at Harper's Ferry, West Virginia. The Potomac River continues as the border between Maryland and Virginia. These waters flow approximately 200 miles in a southeasterly direction along Loudoun and Fairfax counties to its confluence with the Chesapeake Bay in Northumberland County. Approximately 2,298 of the 14,700 square miles of the Potomac River sub-basin drainage area lie in Virginia. The rest covers four states and the District of Columbia.

Gently sloping hills and valleys from Harpers Ferry to approximately 45 miles downriver characterize the topography of the upper Piedmont region of the Potomac River sub-basin. In the central Piedmont area, the profile is rather flat until it nears the fall line at Great Falls, where the stream elevation rapidly descends from over 200 feet to sea level. Tributaries in the central Piedmont exhibit moderate and near constant profiles. Their flat slope largely characterizes streams in the Coastal Plain area. Approximately 40% of the Potomac River basin is forested, 33% is farmland and pasture and an estimated 27% is urban.

The 2010 population for the Potomac-Shenandoah River basin was approximately 3,141,200. The majority of the population resides in urban Virginia surrounding Washington, D.C. All or part of the following jurisdictions lie within the basin: Counties – Arlington, Augusta, Clarke, Fairfax, Fauquier, Frederick, Highland, King George, Loudoun, Northumberland, Page, Prince William, Rockingham, Shenandoah, Stafford, Warren, and Westmoreland; Cities – Alexandria, Fairfax, Falls Church, Harrisonburg, Manassas, Manassas Park, Staunton, Waynesboro, and Winchester.

The Potomac-Shenandoah River basin is divided into eight USGS hydrologic units as follows: HUC 02070001- South Branch Potomac; HUC 02070004 - Conococheague-Opequon; HUC 02070005 - South Fork Shenandoah; HUC 02070006 - North Fork Shenandoah; HUC 02070007 - Shenandoah; HUC 02070008 - Middle Potomac-Catoctin; HUC 02070010 - Middle Potomac-Anacostia-Occoquan; HUC 02070011 - Lower Potomac. The eight hydrologic units are further divided into 92 waterbodies or watersheds and 181 6th order sub-watersheds.

Public Concerns over Excessive Algae in the Shenandoah River

During the public comment periods for the 2012 and 2014 Integrated Reports, DEQ received comments from citizens regarding the presence of algae in the Shenandoah River and concern that the algae in the river impaired the recreation designated use. In response to citizen comments, additional photographic evidence, and recent information provided by citizen groups, DEQ determined that there was uncertainty about the attainment status of the recreation designated use for 7 assessment units (5 stream segments) in the Shenandoah River basin. These waters (listed in Table 4.3-a) comprise a total of 25 stream miles and were classified in the 2014 Assessment Database as Category 3C for the recreation use, which indicates an observed effect, but insufficient data to determine whether or not the recreation use is supported. These segments have been prioritized for follow-up monitoring in 2016 and 2017 by DEQ to develop and test field methods for estimating the percent coverage of river bottom by filamentous algae that are scientifically based, defensible and reproducible. DEQ made additional commitments for future activities, including decisions on thresholds for percent coverage that constitute a "nuisance" condition and impairment under the general narrative water quality standard, and inclusion of such thresholds in DEQ's guidance for the 2018 Assessment Report.

In May 2016, DEQ began developing a scientifically valid field method for evaluating algae cover that can be applied consistently throughout the state, with an initial study area focused on the Shenandoah River. The 2016 field season extended through early November. To meet the demanding field schedule, DEQ hired two employees who were solely dedicated to algae monitoring. DEQ's monitoring staff visited each of the five sites weekly, as conditions permitted. During 2016, DEQ tested three lateral transect methods to estimate percent cover by filamentous algae at evenly spaced increments along the wetted channel width. Of the three methods tested, staff found that the Quadrat method results showed greatest agreement among field staff. DEQ found that the lateral transects provided good estimates of algal percent cover, but given the potential for bias and error, staff began reviewing analytical methods to more objectively and consistently determine numeric algae densities. Based on methods in place in Montana[1], DEQ staff began collecting chlorophyll-a (the green pigment in algae that coverts light to energy) and Ash Free Dry Mass (a weight measurement) data to estimate algal densities on the substrate of the rivers. 15 data points were collected in the 2016 field season.

What is the Quadrat Method?

For the Quadrat method, monitoring staff use a view scope to compare percent coverage of algae within a square frame to a visual percent cover chart. Several measurements are taken along the width of the channel. The individual values are averaged to generate a single estimate of percent cover by filamentous algae for the site.

The results of the 2016 monitoring season were made available on the agency's Shenandoah River Algae website[2], and presented to the public during a public information webinar in December 2016 and at the Environment Virginia Conference in April 2017. In general, the results from the 2016 monitoring season indicate that more data is needed before decisions on recreation use impacts can be made. Many of the South Fork Shenandoah segments showed little to no algae throughout the 2016 growing season. The North Fork segments did have filamentous algae present during periods of prolonged low flow, but the algae was ephemeral and dependent on multiple variables including precipitation, river flows, and sunlight. Consequently, the 7 Assessment Units remain in Category 3C in the 2016 IR.

[1] http://deq.mt.gov/Portals/112/Water/WQPB/QAProgram/Documents/PDF/SOPs/WQPBWQM-011v6_FNL.pdf

[2] http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityAssessments/ShenandoahAlgae.aspx

During the 2017 growing season, DEQ staff conducted algal monitoring weekly from June through October. Monitoring focused on the collection of transect data and analytical data, as conditions allowed. Additional goals include:

- further developing the Monitoring Plan to define sample intervals;
- proposing impairment thresholds and assessment methods based on 2016 and 2017 data results;
- holding a public webinar to present updated findings and recommendations to the public;
- incorporating decisions on impairment thresholds and assessment method as well as information on monitoring results in 2018 Integrated Report;
- working with local citizen monitoring groups to determine meaningful and discrete ways in which they can assist with this effort.

DEQ will continue to consider recommendations from the Interstate Commission on the Potomac River Basin, the Academic Advisory Committee, and the Mid-Atlantic jurisdictions that comprise EPA Region III (PA, WV, MD, VA, DE and DC).

Table 4.3-a. Assessment units in the Shenandoah River that have been classified as having an indeterminate recreation use status, with algae identified as a potential cause of impairment.

James River Basin

The James River Basin occupies the central portion of Virginia and covers 10,265 square miles or approximately 24% of the Commonwealth's total land area. It is Virginia's largest river basin and is made up of the Upper, Middle, and Lower James River sub-basins as well as the Appomattox River sub-basin.

The James River basin is defined by both hydrologic and political boundaries. The Potomac-Shenandoah River basin, the Rappahannock River basin and the York River basins bound the basin to the north. The southern boundary is made up of the New River basin, the Roanoke River basin and the Chowan River basin. Its headwaters originate along the Virginia/West Virginia state line.

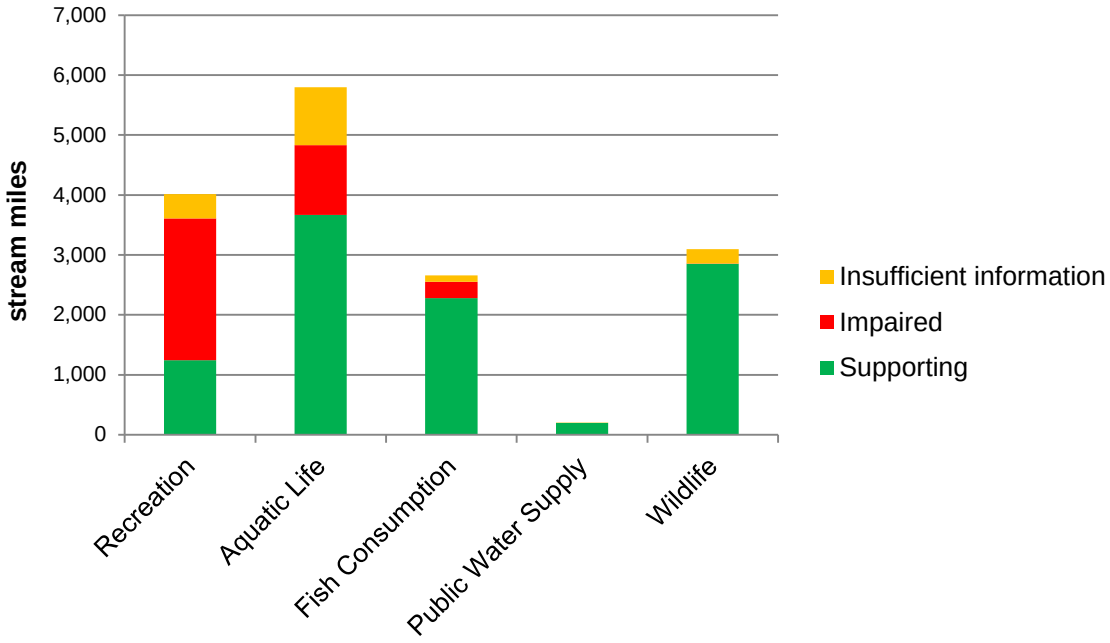
The James River basin begins in the Alleghany Mountains and flows in a southeasterly direction to Hampton Roads where it enters the Chesapeake Bay. The James is formed by the confluence of the Jackson and Cowpasture Rivers and flows 242 miles to the Fall Line at Richmond and another 106 miles to the Chesapeake Bay.

The topography of the James River basin varies throughout the four physiographic provinces that it spans. The Valley and Ridge Province extends from the Appalachian Plateau in West Virginia to the Blue Ridge Province. The Blue Ridge Province, a remnant of a former highland, differs from the Valley and Ridge Province. It is a province of rugged terrain with steep slopes and narrow ridges in the north and broad moderate slopes in the south. The Piedmont Province extends to the Fall Line and has scattered hills and small mountains, gradually turning into gently rolling slopes and lower elevation in the eastern portion of the province. The Fall Zone separates the Coastal Plain Province from the Piedmont. The Fall Zone is a three-mile stretch of river running through Richmond where the river descends 84 feet as it flows from the resistant rocks of the Piedmont to the softer sediments of the Coastal Plain.

Over 65% of the James River basin is forested, with 19% in cropland and pasture. Approximately 12% is considered urban. The 2010 population for the James River basin was approximately 2,892,000. This population is concentrated in two metropolitan areas: Tidewater, with over one million people, and the Greater Richmond – Petersburg area with over 650,000. Two smaller population centers are the Lynchburg and Charlottesville areas, each with over 100,000 people. All or portions of the following 38 counties and 17 cities lie within the basin: counties - Albemarle, Alleghany, Amelia, Amherst, Appomattox, Augusta, Bath, Bedford, Botetourt, Buckingham, Campbell, Charles City, Chesterfield, Craig, Cumberland, Dinwiddie, Fluvanna, Giles, Goochland, Greene, Hanover, Henrico, Highland, Isle of Wight, James City, Louisa, Montgomery, Nelson, New Kent, Nottoway, Orange, Powhatan, Prince Edward, Prince George, Roanoke, Rockbridge, Surry, and York; cities - Buena Vista, Charlottesville, Chesapeake, Colonial Heights, Covington, Hampton, Hopewell, Lexington, Lynchburg, Newport News, Norfolk, Petersburg, Portsmouth, Richmond, Suffolk, Williamsburg, and Virginia Beach.

Average annual precipitation is 42.5 inches. Average annual snowfall amount ranges from over 30 inches in the mountains to less than 10 inches along the coast.

Major tributaries to the James River are Jackson River, Cowpasture River, Craig Creek, Maury River, Tye River, Rockfish River, Slate River, Rivanna River, Willis River, Appomattox River, Chickahominy River, Pagan River, Nansemond River, and the Elizabeth River.



The James River Basin is divided into eight USGS hydrologic units as follows: HUC 02080201 –Upper James, HUC 02080202 – Maury, HUC 02080203 – Upper Middle James, HUC 02080204 – Rivanna, HUC 02080205 – Lower Middle James, HUC 02080206 – Lower James, HUC 02080207 – Appomattox, and HUC 02080208 – the Elizabeth. The eight hydrologic units are further divided into 109 waterbodies or watersheds and 298 6th order sub-watersheds.

Basin assessment information is presented in the following tables and figures.

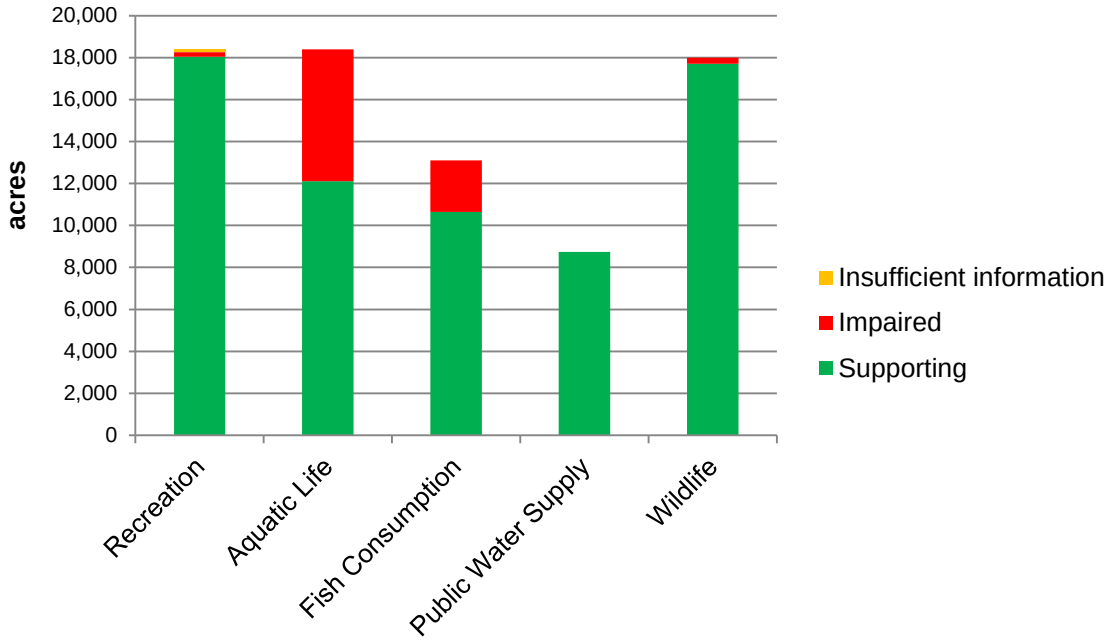


Figure 4.3-2 Designated Use support summary for the James River basin.

Rappahannock River Basin

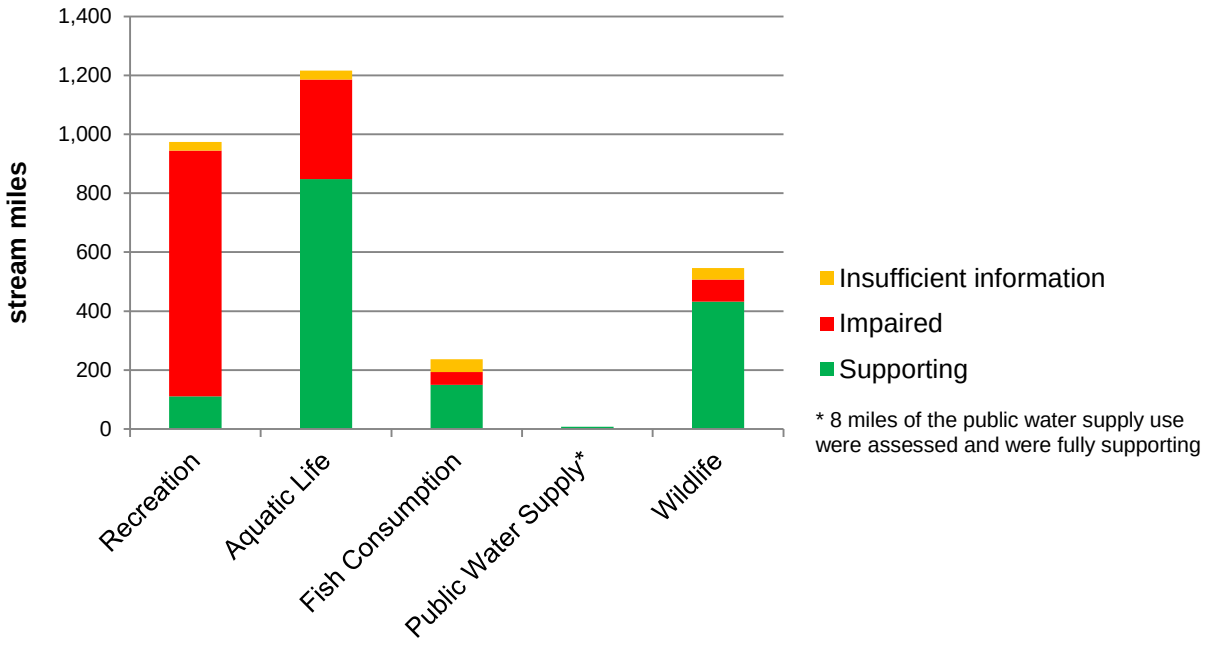
The Rappahannock River basin is located in the northeastern portion of Virginia and covers 2,712 square miles or approximately 6% of the Commonwealth's total area.

The Rappahannock River basin is bordered by the Potomac-Shenandoah basin to the north and the York River basin and Chesapeake/Atlantic Coastal basin to the south and east. The headwaters lie in Fauquier and Rappahannock counties and flow in a southeasterly direction to its confluence with the Chesapeake Bay between Lancaster and Middlesex counties. The Rappahannock River basin is 184 miles in length and varies in width from 20 to 50 miles. The Rappahannock River basin's major tributaries are the Hazel River, Thornton River, Mountain Run, Rapidan River, Robinson River, Cat Point Creek, and the Corrotoman River.

The topography of the Rappahannock River basin changes from steep slopes to flat land as it flows from the Blue Ridge Mountains to the Chesapeake Bay. About 51% of the basin land is forested, while pasture and cropland make up another 36%. Only about 6% of the land area is considered urban.

Most of the Rappahannock River basin lies in the eastern Piedmont and Coastal Plain areas of the Commonwealth while its headwaters, located on the eastern slopes of the Blue Ridge, are considered to be in the northwestern Piedmont section.

The 2010 population of the Rappahannock River basin was approximately 483,770. The basin is mostly rural in character with no large population centers. However, the basin has seen increasing urban pressure from the influence of metropolitan Washington in the Fredericksburg and Fauquier areas of the basin. All or portions of the following 17 counties and one city lie within the basin: Albemarle, Caroline, Culpeper, Essex, Fauquier, Greene, King George, Lancaster, Madison, Middlesex, Northumberland, Orange, Rappahannock, Richmond, Spotsylvania, Stafford, and Westmoreland; City - Fredericksburg.



The Rappahannock River Basin is divided into two USGS hydrologic units as follows: HUC 02080103 – Rapidan – Upper Rappahannock; and HUC 02080104 – Lower Rappahannock. The two hydrologic units are further divided into 26 waterbodies or watersheds and 74 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

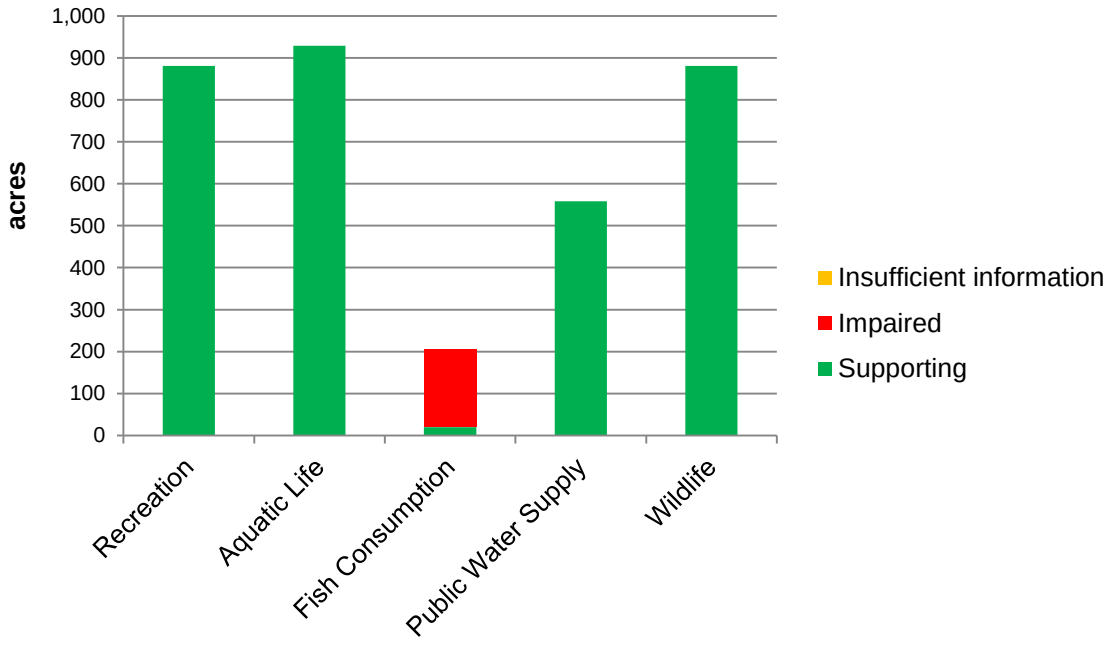


Figure 4.3-3 Designated use support summary for the Rappahannock River basin. (Note: Waters that have some data, but not enough to determine use support, are classified as having "Insufficient information".)

Roanoke River Basin

The Roanoke River basin covers 6,393 square miles or approximately 15% of the Commonwealth's total area. In addition to the Roanoke itself, the basin also contains the Yadkin River sub-basin.

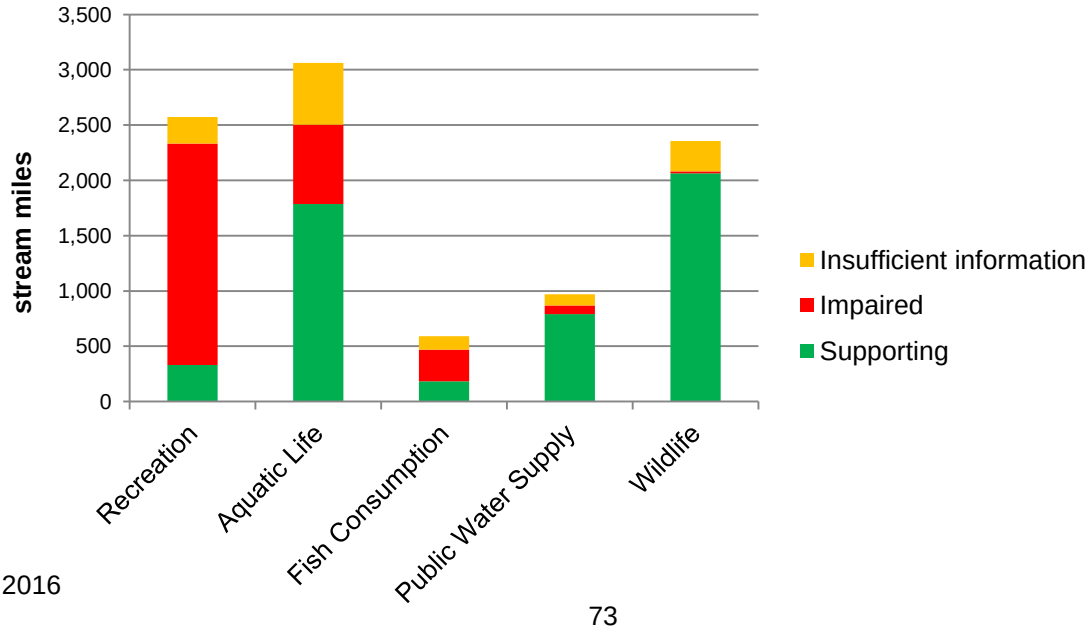
The Virginia portion of the Roanoke River basin is defined by both hydrologic and political boundaries. The basin is bound by the James River basin on the north, to the east by the Chowan River basin, and to the west by the New River basin. The southern boundary of the basin is the Virginia/North Carolina state line.

The topography of the Roanoke River basin ranges from steep slopes and valleys in the Valley and Ridge Province to gently sloping terrain east of the mountains in the Piedmont Province.

The Roanoke River basin headwaters begin in the mountainous terrain of eastern Montgomery County and flow in a southeasterly direction to the Virginia/North Carolina state line. The Roanoke basin passes through three physiographic provinces- the Valley and Ridge Province to the northwest, and the Blue Ridge and Piedmont Provinces to the southeast.

The Roanoke watershed is large enough to accommodate two major reservoirs, Smith Mountain and Leesville Lakes to the north and Kerr Reservoir and Lake Gaston located at the junction of the Roanoke River and the North Carolina state line. These reservoirs range in size from the 33,300 acre Kerr Reservoir to the 2,600-acre Leesville Lake. These impoundments are used for both recreation and hydroelectricity. Major tributaries in the northern section of the basin are the Little Otter and Big Otter Rivers along with the Blackwater and Pigg Rivers. Major tributaries in the southern portion include the Dan River, Smith River, and Banister River. Over 62% of the Roanoke River Basin is forested, while nearly 25% is in cropland and pasture. Approximately 10% is considered urban.

The 2010 population for the Roanoke River Basin was approximately 943,200. All or portions of the following 17 counties and 4 cities lie within the basin: counties – Appomattox, Bedford, Botetourt, Brunswick, Campbell, Carroll, Charlotte, Floyd, Franklin, Grayson, Halifax, Henry, Mecklenburg, Montgomery, Patrick, Pittsylvania, and Roanoke; cities – Danville, Martinsville, Roanoke, and Salem.



The Roanoke River basin is divided into seven USGS hydrologic units as follows: HUC 03010101 – Upper Roanoke; HUC 03010102 – Middle Roanoke; HUC 03010103 – Upper Dan; HUC 03010104 – Lower Dan; HUC 03010105 – Banister; HUC 03010106 – Roanoke Rapids and HUC 03040101 – Upper Yadkin. The seven hydrologic units are further divided into 87 waterbodies or watersheds and 202 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

Figure 4.3-4 Designated use support summary for the Roanoke River basin. (Note: Waters that have some data, but not enough to determine use support, are classified as having "Insufficient information".)

Chowan River-Dismal Swamp Basin

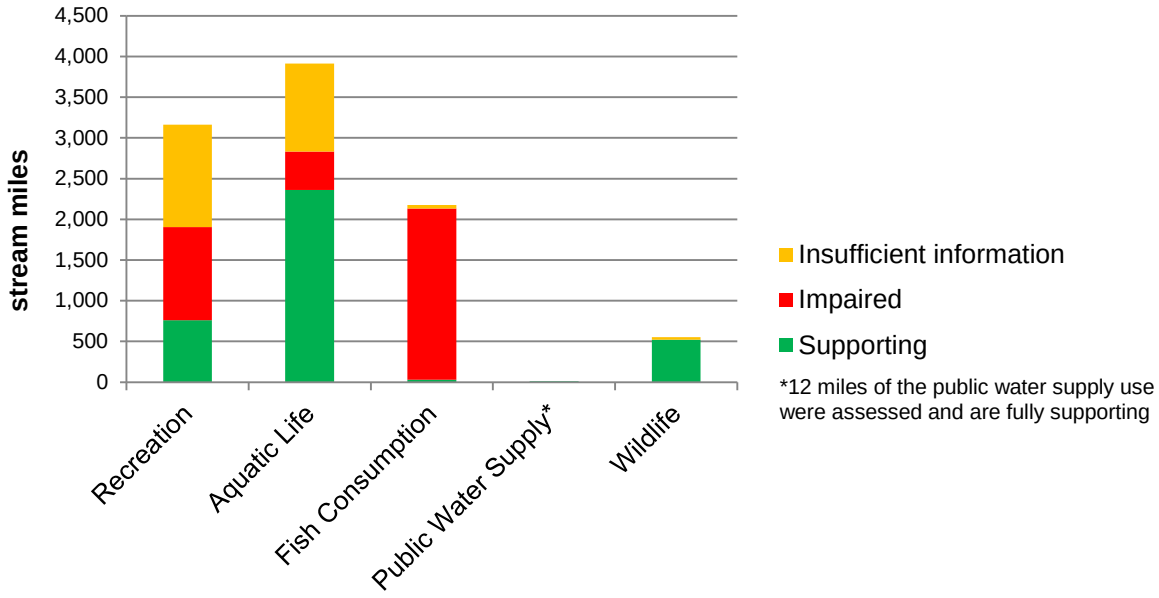
The Chowan River and Dismal Swamp basin is located in the southeastern portion of Virginia and covers 4,220 square miles or approximately 10% of the Commonwealth's total area.

The basin extends eastward from Charlotte County to the Chesapeake Bay. The Chowan River-Dismal Swamp basin in Virginia is defined by both hydrologic and political boundaries - the James River basin to the north, the Chesapeake/Atlantic and Small Coastal River basins to the east, the Roanoke River basin to the west and the Virginia/North Carolina State line to the south. The basin is approximately 145 miles in length and varies from 10 to 50 miles in width. The Chowan River-Dismal Swamp basin flows through the Piedmont and Coastal Plain Physiological Provinces. The Chowan portion flows 130 miles from west to east, crossing both the Piedmont and Coastal Plain, while the Dismal Swamp lies entirely within the Coastal Plain. The Piedmont portion is characterized by rolling hills, steeper slopes and somewhat more pronounced stream valleys. The Coastal Plain, in contrast, is nearly flat with a descending series of terraces.

The Chowan River-Dismal Swamp basin is mostly rural with approximately 64% of its land covered by forest. Cropland and pasture make up another 28%, while only about 6% is classified as urban.

The 2010 population for the Chowan River-Dismal Swamp basin was approximately 597,900. All or portions of the following 13 counties and 6 cities lie within the basin: counties – Brunswick, Charlotte, Dinwiddie, Greensville, Isle of Wight, Lunenburg, Mecklenburg, Nottoway, Prince Edward, Prince George, Southampton, Surry, and Sussex; Cities – Chesapeake, Emporia, Franklin, Petersburg, Suffolk, and Virginia Beach.

Major tributaries of the Chowan River are the Meherrin, the Nottoway and the Blackwater. The Nottoway and the Blackwater join at the Virginia/North Carolina state line to form the Chowan River. The Dismal Swamp portion is mostly flat with many swamp and marshland areas.



The Chowan River-Dismal Swamp basin is divided into five USGS hydrologic units as follows: HUC 03010201 – Nottoway; HUC 03010202 – Blackwater; HUC 03010203 – Chowan; HUC 03010204 – Meherrin; and HUC 03010205 – Albemarle Sound. The five hydrologic units are further divided into 42 waterbodies or watersheds and 127 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

Tennessee-Big Sandy River Basin

The segment of the Tennessee and Big Sandy River basin which lies in Virginia is made up of the Holston, Clinch-Powell, and Big Sandy River sub-basins. These sub-basins are located in the extreme southwest portion of Virginia and cover 4,132 square miles or approximately 10% of the Commonwealth's total land area.

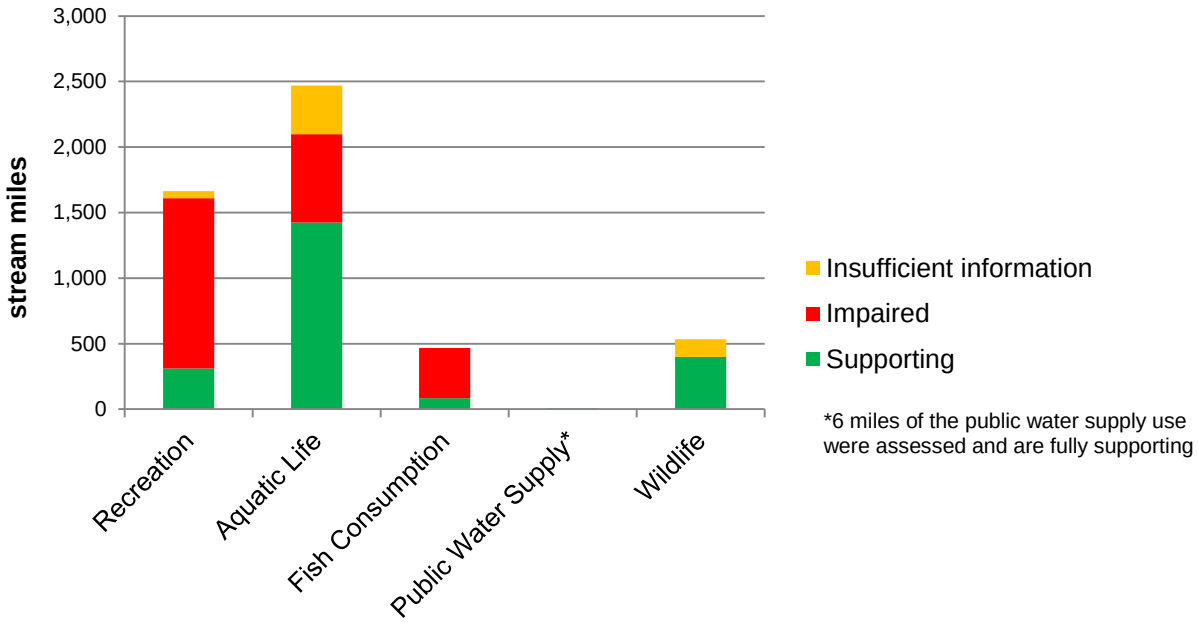
The Virginia portion of the Tennessee-Big Sandy River basin is defined by both hydrologic and political boundaries. The West Virginia state line lies to the north, Kentucky to the west, and Tennessee to the south. The New River basin makes up the eastern boundary.

While numerous southwestern Virginia streams feed the Tennessee and Big Sandy Rivers, neither river forms within the Commonwealth itself. The Big Sandy sub-basin contains the Levisa and Tug Forks that flows northward into Kentucky forming the Big Sandy River. The southwestward flowing Holston, Clinch, and Powell tributaries form the Tennessee River in Tennessee. Both of the major river sub-basins eventually empty into the Gulf of Mexico via the Ohio and Mississippi Rivers.

The Tennessee-Big Sandy River basin spans three physiographic provinces: Appalachian Plateau, Valley and Ridge, and the Blue Ridge. The Big Sandy portion of the basin lies within the Appalachian Plateau. This province is characterized as rugged, with mountainous terrain and steep valleys. Parallel valleys and ridges running in a northeast to southwest direction characterize the Tennessee portion, lying in the Valley and Ridge Province. A small portion of the basin, located in the Blue Ridge Province, is more like a plateau with no single, prominent ridge that characterizes the province to the southeast.

Within Virginia, approximately 48% of the Tennessee River basin is forested, while cropland and pasture make up another 39.7%. The Big Sandy portion of the basin is approximately 86% forest, with only about 5% in cropland and pasture. Urban areas make up only a small percentage of the total land area.

The 2010 population for the Tennessee-Big Sandy River Basin was approximately 458,700. All or parts of the following jurisdictions lie within the basin: counties – Bland, Buchanan, Dickenson, Grayson, Lee, Russell, Scott, Smyth, Tazewell, Washington, Wise, and Wythe; Cities – Bristol and Norton.



The Tennessee-Big Sandy River basin is divided into six USGS hydrologic units as follows: HUC 05070201 – Tug Fork; HUC 05070202 – Upper Levisa; HUC 06010101 – North Fork Holston; HUC 06010102 - South and Middle Fork Holston; HUC 06010205 – Upper Clinch; and HUC 06010206 – Powell River. The six hydrologic units are further divided into 56 waterbodies or watersheds and 135 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

Figure 4.3-6 Designated use support summary for the Tennessee-Big Sandy River basin. (Note: Waters that have some data, but not enough to determine use support, are classified as having "Insufficient information".)

Chesapeake Bay/Atlantic Ocean and Small Coastal Basins

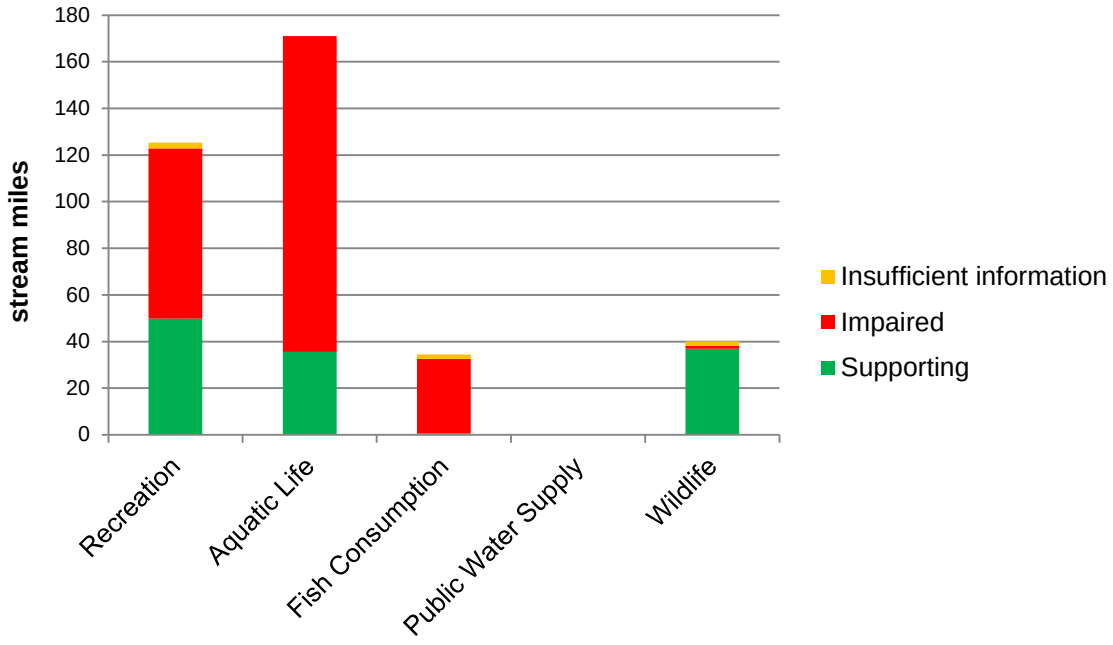
The Chesapeake Bay/Atlantic Ocean and small coastal basins are located in the eastern part of Virginia and covers 3,592 square miles or approximately 8% of the Commonwealth's total land area. The combined basins encompass the small bays, river inlets, islands and shoreline immediately surrounding the Chesapeake Bay and the southern portion of the Delmarva Peninsula. These basins also include the Chesapeake Bay itself.

The Chesapeake Bay/Atlantic Ocean and small coastal basins are defined by both hydrologic and political boundaries. The Potomac River, the Rappahannock River, the York River, the James River, and the Chowan River-Dismal Swamp basins border the small coastal basins to its west. The Eastern Shore portion is bordered on the west by the Chesapeake Bay, on the north by Maryland, and on the east by the Atlantic Ocean.

The topography of the Chesapeake Bay/Atlantic Ocean and small coastal basins vary little. The basins lie within the Coastal Plain Physiographic Province where elevations average no more than a few feet above sea level. More significant elevation occurs along the central spine of the Eastern Shore portion, which forms a plateau about 45 feet above sea level. Much of these basins consist of marshland. About 30% of the Chesapeake Bay/Atlantic Ocean and small coastal basins are forested, while nearly 22% is in cropland and pasture. Approximately 24% is considered urban.

The 2010 population for the Chesapeake Bay/Atlantic Ocean and small coastal basins was approximately 741,800. All or portions of the following jurisdictions lie within these basins: Counties – Accomack, Essex, Gloucester, King and Queen, Lancaster, Matthews, Middlesex, Northampton, Northumberland, and York; Cities – Hampton, Newport News, Norfolk, Poquoson, and Virginia Beach.

Tributaries in the Chesapeake Bay/coastal basins drain into the Chesapeake Bay or the Atlantic Ocean. Major tributaries flowing into the Chesapeake Bay from the western shore are the Great Wicomico River, Piankatank River, Fleets Bay, Mobjack Bay including the East, North, Ware, and Severn Rivers, Poquoson River, Back River and Lynnhaven River. Tributaries in the Eastern Shore portion that drain into the Bay are Pocomoke River, Onancock, Pungoteague, Occohannock, and Nassawadox Creeks. Machipongo River, Assawoman Creek, Parker Creek, Folly Creek, and Finney Creek drain east directly into the Atlantic Ocean.



The Chesapeake Bay/Atlantic Ocean and small coastal basins are divided into seven USGS hydrologic units as follows: HUC 02060009 – Pocomoke; HUC 02060010 – Chincoteague; HUC 02080101 – Lower Chesapeake Bay; HUC 02080102 – Great Wicomico-Piankatank; HUC 02080108 – Lower Lynnhaven-Poquoson; HUC 02080109 – Western Lower Delmarva; and HUC 02080110 – Tangier. The seven hydrologic units are further divided into 24 waterbodies or watersheds and 73 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

York River Basin

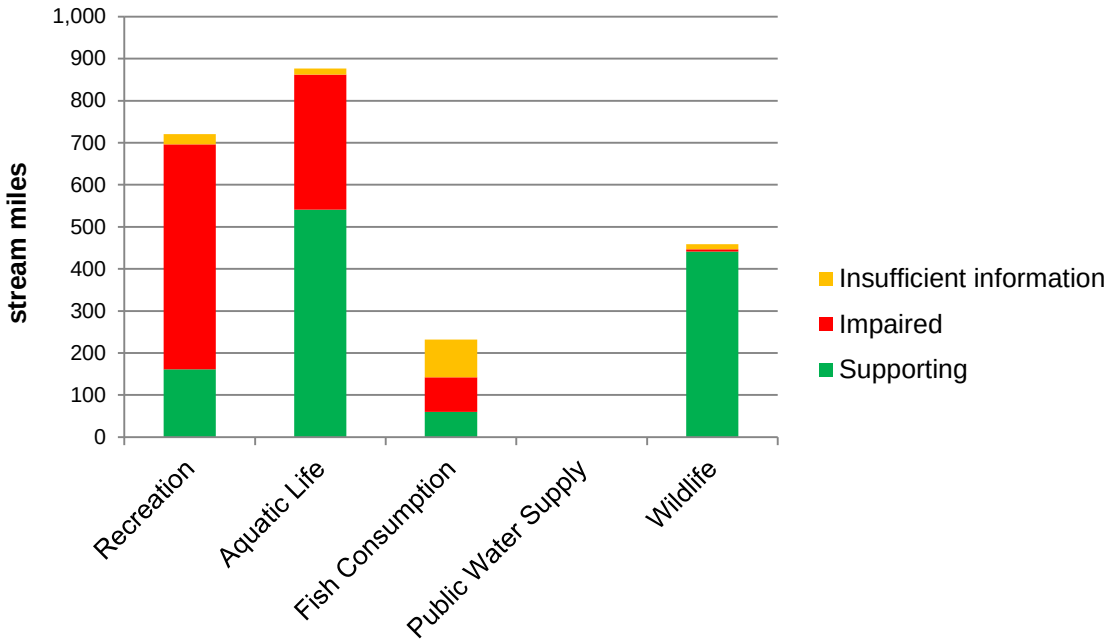
The York River basin lies in the central and eastern section of Virginia and covers 2,674 square miles or 6% of the Commonwealth's total area. It is defined by hydrologic boundaries. The basin is bound by the Rappahannock River basin to the north, the James River basin to the south and west and the Chesapeake Bay/Atlantic Ocean and small coastal basins to the east.

The headwaters of the York River begin in Orange County and flow in a southeasterly direction for approximately 220 miles to its mouth at the Chesapeake Bay. The basin's width varies from five miles at the mouth to 40 miles at its headwaters.

The basin is comprised of the York River and its two major tributaries, the Pamunkey and the Mattaponi Rivers. The York River itself is only about 30 miles in length. The Pamunkey River's major tributaries are the North and South Anna Rivers and the Little River, while the major Mattaponi tributaries are the Matta, Po, and Ni Rivers.

Lying in the Piedmont and Coastal Plain physiographic provinces, the basin's topography is characterized by slightly rolling hills at the headwaters or extreme western portion, to gently sloping hills and flat farmland near its mouth. Tributaries in the central Piedmont exhibit moderate and near constant profiles. Their flat slope largely characterizes streams in the Coastal Plain. Approximately 65% of the land area is forest. Farmland and pasture account for approximately 20% of the land area. Approximately 10% of the river basin land area is urban.

The 2010 population for the York River basin was approximately 435,400. The majority of the population is rural and is evenly distributed throughout the basin. The only major city that falls within this basin is a portion of Williamsburg. All or portions of the following thirteen counties lie within the basin: Albemarle, Caroline, Fluvanna, Gloucester, Goochland, Hanover, James City, King and Queen, King William, Louisa, New Kent, Orange, Spotsylvania, and York.



The York River basin is divided into three USGS hydrologic units as follows: HUC 02080105 – Mattaponi; HUC 02080106 - Pamunkey and HUC 02080107 - York. The three hydrologic units are further divided into 27 waterbodies or watersheds and 69 6th order sub-watersheds.

Basin assessment information is presented in the following figures and tables.

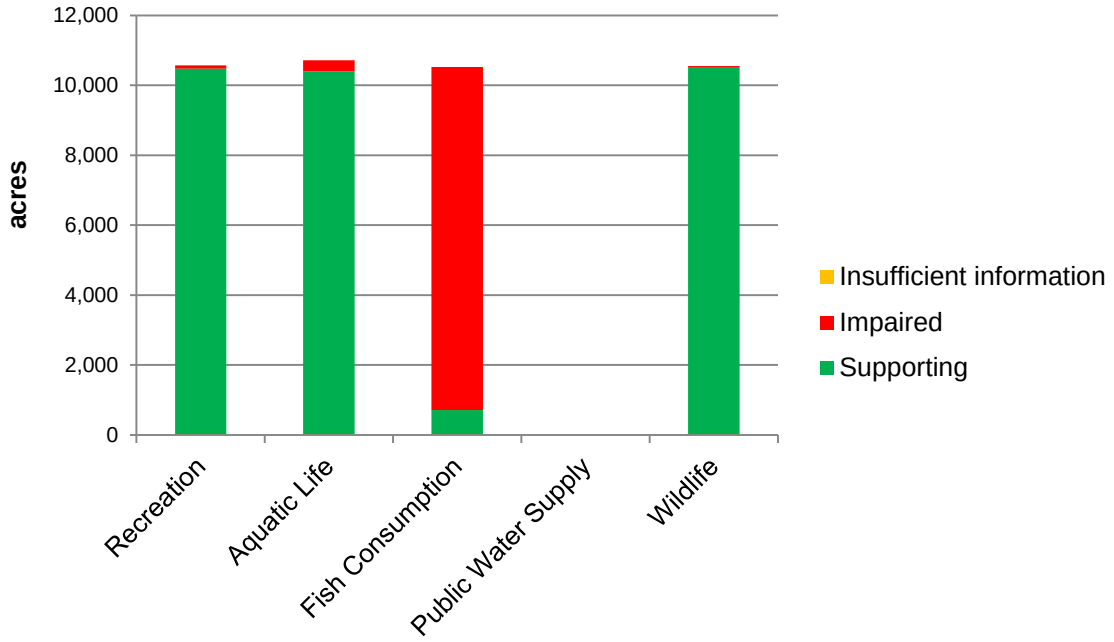


Figure 4.3-8 Designated use support summary for the York River basin. (Note: Waters that have some data, but not enough to determine use support, are classified as having "Insufficient information".)

New River Basin

The New River basin is located in southwest Virginia and covers 3,068 square miles or approximately 7% of the Commonwealth's total land area. The New River flows from its headwaters in Watauga County, North Carolina in a northeasterly direction to Radford, Virginia, and then in a northwesterly direction to Glen Lyn, where it exits into West Virginia. There it flows to the confluence of the Gauley River forming the Kanawha River, a tributary to the Ohio River.

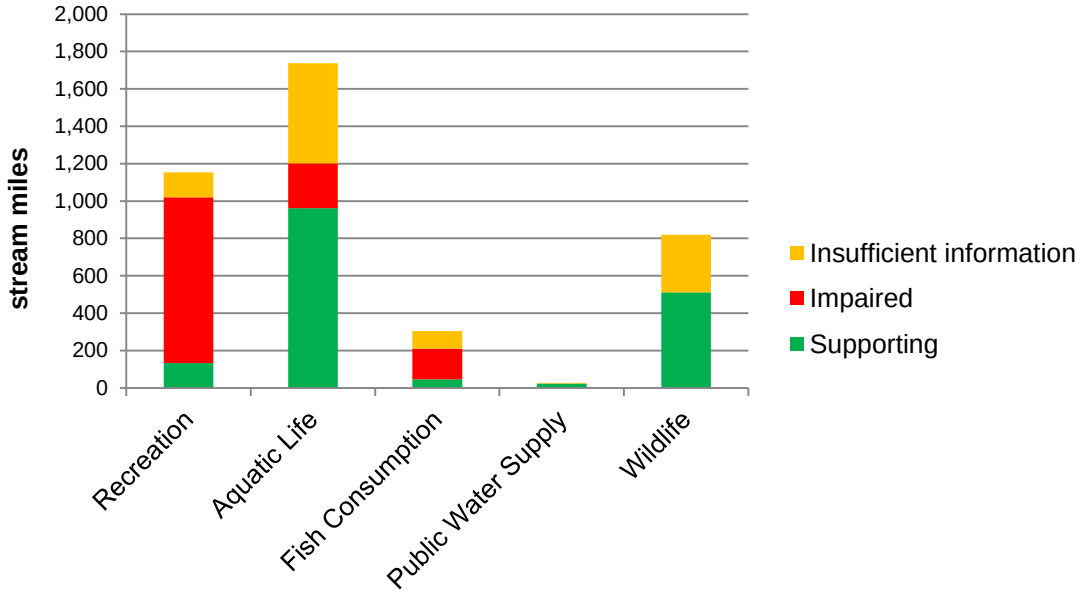
The New River basin in Virginia is defined by both hydrologic and political boundaries. It is bordered by the James River basin and Roanoke River basin to the east, and the Tennessee and Big Sandy River basin to the west. The southern boundary of the Virginia portion is the North Carolina state line and its northwest boundary is the West Virginia state line.

The New River basin runs 115 miles in length from Blowing Rock, North Carolina to Bluestone Dam near Hinton, West Virginia with a maximum basin width of 70 miles near Rural Retreat, Virginia. The Virginia portion of the New River basin is 87 miles in length.

The topography of the New River basin is generally rugged; the upper reaches of its tributaries are extremely steep. High mountains, narrow valleys and steep ravines characterize the basin. There are ten tributaries in the Upper New River basin each having more than 100 square miles in drainage area and many others with forty or more square miles.

The New River basin is the least densely populated of the Commonwealth's major river basins. The higher elevations of the basin have steep slopes and are thickly forested, while the mount bases are mostly used for agriculture. Approximately 59% of its land is forested. Cropland and pasture make up another 35%, with approximately 3% considered urban.

The 2010 population for the New River basin was approximately 412,900. All or portions of the following jurisdictions lie within the basin: Counties - Bland, Carroll, Craig, Floyd, Giles, Grayson, Montgomery, Pulaski, Smyth, Tazewell, Wythe; Cities - Galax and Radford.



The New River basin is divided into two USGS hydrologic units as follows: HUC 05050001 – Upper New; and HUC 05050002 – Middle New. The two hydrologic units are further divided into 38 waterbodies or watersheds and 88 6th order watersheds.

Basin assessment information is presented in the following figures and tables.

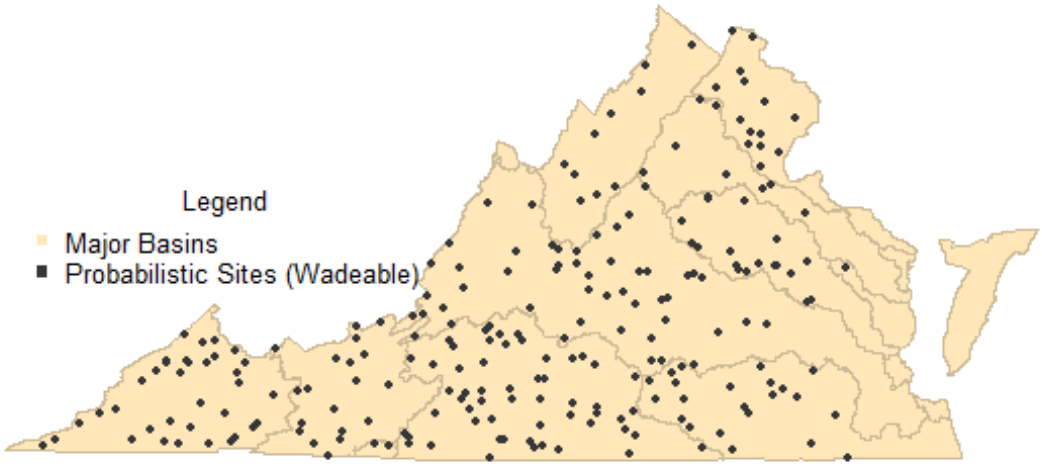
CHAPTER 4.4 FRESHWATER PROBABILISTIC MONITORING RESULTS

Executive Summary

Probabilistic monitoring is designed to answer questions about statewide and regional water quality conditions. The DEQ Probabilistic Monitoring Program, or ProbMon, has evaluated nearly 1000 wadeable sites statewide since the program began in 2001 and sampled 646 stations (Figure 4.4-3). Over 250 sites were sampled during the 2016 assessment period (Figure 4.4-2). Although the majority of water quality parameters meet applicable water quality criteria, the biological condition of Virginia streams are rated as degraded in approximately 46% of stream miles (Figure 4.4-1). Biological condition is assessed based on the ecological health of aquatic macroinvertebrates. Degraded aquatic macroinvertebrate communities are believed to be caused in part by stressors such as streambed sedimentation, habitat disturbance, and nutrients. The most frequently occurring water quality problems are presented in Figure 4.4-1. ProbMon is a cost-effective way to evaluate Virginia streams and rivers, test new sampling methods, and support other DEQ water quality management activities like water quality standards development and Total Maximum Daily Load (TMDL) studies.

Figure 4.4-1. Percentage of stream miles with water quality parameters exceeding criteria/screening values. Red bars indicate a parameter with no water quality standard and green bars indicate a parameter with water quality standard or screening value. Data represents 2009 - 2014 Integrated Report sampling window.



Introduction

Probabilistic monitoring is designed to answer basic questions like: “What are the primary water quality problems in Virginia? How widespread are these problems, and what pollutants cause the greatest environmental stress to Virginia’s water resources?” The Virginia General Assembly, citizens, environmental stakeholders, and the United States Environmental Protection Agency (USEPA) have encouraged the Virginia Department of Environmental Quality (DEQ) to answer these questions and to establish baseline water quality conditions for Virginia’s streams and rivers. ProbMon is one component of DEQ’s Water Quality Monitoring Strategy. Typically water quality monitoring stations are located at bridges, boat ramps or other public access points. These monitoring stations are known as targeted monitoring sites. Targeted monitoring has great utility for identifying impaired waters, supporting TMDL and Implementation Plan modeling efforts, monitoring water quality trends over time, tracking local pollution events, and monitoring regulatory compliance of pollution sources. However, it is not appropriate to extrapolate results from targeted stations to un-sampled watersheds over large geographic areas. Data

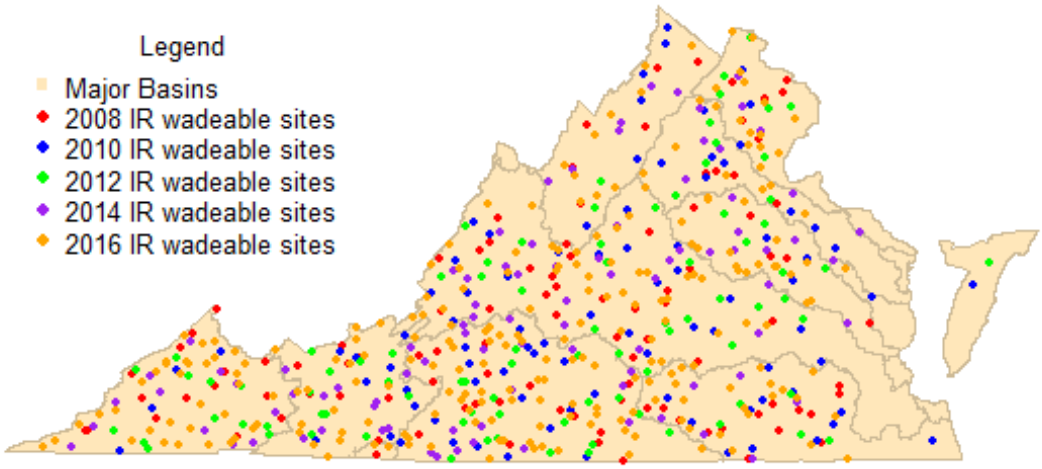
to address water quality questions from large geographic areas are best obtained from statistically designed studies with randomly chosen sample locations.

In Virginia, ProbMon sites are randomly selected using USEPA's probability survey design program (Stevens 1997; USEPA 2006). DEQ samples 50 to 60 random stations per year throughout Virginia for a variety of chemical, biological, and habitat parameters. From January 1st, 2009 until December 31st, 2014 DEQ evaluated 398 sites and sampled 254 stations (Figure 4.4-2). From 2001 to 2014, 646 sites have been sampled (Figure 4.4-3). In some cases, stations were evaluated, but not sampled for a variety of reasons including: the stream was not perennial, it was saltwater influenced, or the landowner denied access.

Figure 4.4-2. Virginia probabilistic monitoring locations from 2009-2014 (n=254).

Estimates of percent river miles not meeting water quality criteria or established screening values are reported with 95% confidence intervals. The sampling frame provided by USEPA for Virginia streams and rivers includes 49,100 miles. It is important to note that the total amount of assessed river miles may vary to some extent by parameter. This number varies based on whether a monitoring tool was appropriate for the sampling location. For example, DEQ biological monitoring tools are not validated for streams without a defined channel, thus streams dominated by wetlands cannot be assessed (approximately 5,000 miles). The actual number of target stream miles (perennial, flowing freshwater) is much less because several thousands of stream miles are not perennial (e.g. the stream was dry when DEQ visited) or were found to be saltwater influenced. There is an estimated 1,200 miles of non-wadeable streams (also referred to as boatable sites), which must be sampled using large river habitat and biological sampling methods. Non-wadeable and wadeable watersheds and sample sites sampled since 2001 are presented in Figure 4.4-4. Large river data collection, using a non-wadeable (boatable) methodology, is underway and the results will be included in future integrated report chapters. The ProbMon chapter provides estimates for all perennial, non-tidal, wadeable stream and river miles which equates to approximately 41,500 miles.

Figure 4.4-3. Virginia probabilistic monitoring wadeable locations from 2001-2014 (n=646).



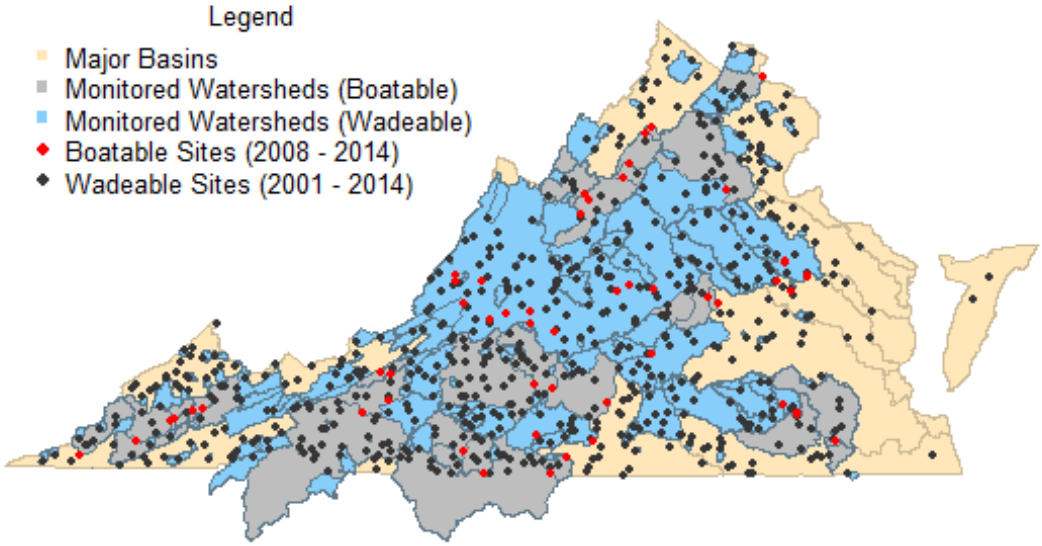


Figure 4.4-4. Virginia probabilistic monitoring wadeable and boatable watersheds and sample sites from 2001-2014 (n=715).

Parameters with Water Quality Standards or Screening Values

Dissolved oxygen, pH, temperature, metals (dissolved and sediment), organic chemicals, and bacteria have applicable water quality criteria or screening values. Water quality standards are regulatory thresholds developed to protect water quality conditions in support of swimming, fishing, and aquatic life designated uses. Screening values are non-regulatory thresholds used to interpret select water quality parameters. Overall results are summarized in Figure 4.4-1 and individual parameter results are discussed below.

Dissolved Oxygen

Dissolved oxygen (DO) is one of the most important measures of water quality for aquatic organisms. Adequate DO is a fundamental physiological requirement for aquatic life. In streams, the DO concentration may be altered by photosynthesis, respiration, nutrient input, re-aeration, and temperature,

all of which have seasonal and daily cycles. This natural variability is reflected in the stream classification component of Virginia's Water Quality Standards (9 VAC 25-260, Commonwealth of Virginia 2011). For example, a mountain stream that supports native trout is expected to have higher DO than a low-gradient, warm water stream. Although expectations for DO concentration vary, all waters (excluding swamps) in Virginia are required to have a DO concentration of 4 mg/L or above. DO standards can be determined on a case-by-case basis if DO deviates due to natural conditions as in swamps and other wetlands (Commonwealth of Virginia 2011). Pollution plays an important role in dissolved oxygen concentration. Human and animal wastes released into streams provide nutrients which cause excessive growth of algae and aquatic plants. As microbes break down organic matter, their respiration can deplete the available DO and the aquatic biota may become stressed and die due to low DO concentration.

ProbMon results indicate that DO conditions for the majority of Virginia's streams and rivers are above the minimum value of 4 mg/L (Table 4.4-1). Most stations with values below 4 mg/L are located in coastal ecoregions where the DO is naturally lower due to swamp conditions. These sites with low DO need to be reviewed as candidates for site specific DO standards. ProbMon results suggest that the majority of mountainous zone waters, stockable trout waters, and natural trout waters are meeting DO standards.

Table 4.4-1. Dissolved oxygen results (2009 - 2014, n=254) compared to Virginia's Water Quality Standard.

Parameter	Below Standard (4 mg/L)
Dissolved Oxygen	0.3% (+/- 0.3%)

pH

Another primary parameter used to evaluate water quality is pH. pH measures the concentration of hydrogen ions in water or the amount of acidity present. Since the pH scale is logarithmic to base 10, a decline in pH by one unit indicates a tenfold decrease in hydrogen ions. At pH 7, a solution is neutral whereas pH values below 7 indicate acidic conditions and values above 7 indicate basic conditions.

Stream pH depends on local geology, ecology, and anthropogenic influences. If a stream has poor buffering capacity as is the case for a stream flowing over granite or shale, it may be naturally acidic. In the case where inorganic acids such as sulfuric or nitric acid are introduced via rain, the low buffering capacity can be rapidly exhausted and the pH declines. The resulting low pH may be detrimental to aquatic biota unaccustomed to low pH. pH values harmful to aquatic life are below 6 or above 9. This range is reflected in Virginia's Water Quality Standards, where most waters must fall within a pH range of between 6 and 9. Natural pH values of 5 or below occur in swamp waters and should not be considered harmful to the native fauna common to those ecosystems. pH standards can be determined on a case-by-case basis if pH deviates due to natural conditions as in swamps and other wetlands (Commonwealth of Virginia 2011).

ProbMon results show that 3.1% of wadeable Virginia streams and rivers are estimated to have pH below 6 (Table 4.4-2). All stations with deviations in pH occurred at sites located in the coastal ecoregion where swamp waters are common, which indicates the need to continue revising site specific water quality standards. DEQ collects additional parameters, including Acid Neutralizing Capacity (ANC) and sulfate data at ProbMon stations to estimate the percent of streams impacted by acid rain and acid mine drainage. High sulfate values in low pH streams are indicative of acid mine drainage whereas streams with low ANC values are susceptible to episodic acidification from acid rain runoff (USEPA 2000). However, based on ProbMon data collected during the 2016 assessment period, DEQ estimates that no pH values are below 6 in the mountain ecoregions.

Table 4.4-2. pH results (2009 - 2014, n=254) compared to Virginia's Water Quality Standard.

Parameter	Below Standard (pH 6)	Above Standard (pH 9)
pH	3.1% (+/- 2.1%)	0% (+/- 0%)

Temperature

Temperature affects water quality by potentially imposing a heat burden on aquatic life and by limiting the level of dissolved oxygen in water. Temperature in streams varies in relation to seasonal and daily changes. Sunlight is the primary source of temperature change. Stream temperature is also influenced by the temperature of the stream bed, groundwater inputs, and air in contact with the water surface. Temperature is inversely related to bank vegetation cover as less cover results in more exposure to the sun and higher temperature. Also, runoff from impervious surfaces in urban areas may increase water temperature. Finally, effluent that is discharged to a waterbody tends to have higher temperature than the receiving stream and may elevate instream water temperature.

Stream temperature has a significant effect on aquatic organisms. It can directly influence the types of organisms found in an aquatic system as well as their growth, behavior, metabolism, reproduction and feeding habits. Virginia's temperature standards reflect the upper limit for the support of different forms of aquatic life (Commonwealth of Virginia 2011). Standards for temperature vary, notably in cold water fisheries, but as a general rule, all waters in Virginia are required to have a temperature at or below 31 or 32 degrees Celsius.

Overall, DEQ estimates that temperature violations will be rare in Virginia's wadeable streams (Table 4.4-3) during the spring and fall. However, it is important to note that ProbMon temperature data is seldom collected during the most stressful hydrologic and weather conditions. In order to properly estimate temperature problems, temperature data must be collected continuously. Continuous temperature collection began in 2016 at probabilistic trend sites.

Table 4.4-3. Temperature results (2009 - 2014, n=254) compared to Virginia's Water Quality Standard.

Parameter	Above Standard (31/32 degrees Celsius)
Temperature	0.0% (+/- 0.0%)

Dissolved Metals

Heavy metals have been identified as an important influence on benthic community structure in streams (Clements et al. 2000). Some taxa appear to be relatively tolerant to metals while other taxa are intolerant of heavy metals. Metals are most biologically available and toxic when dissolved in water. Toxicity of many metals is dependent on water hardness making it necessary to calculate site specific water quality criteria from hardness values. Table 4.4-4 lists the Virginia Water Quality Criteria for metals assuming a hardness (expressed as $CaCO_3$) of 100 mg/L for most dissolved metals. The table also summarizes the number of sites that had detectable analytical results and the number of criterion exceedences based on site specific hardness values.

No samples were measured above their respective chronic or acute sample criteria during the 2016 Integrated Report sample window (2009 - 2014). Results are shown in Table 4.4-4.

Table 4.4-4. Dissolved metals results (2009 - 2014, n=251) compared to Virginia's Water Quality Standards. ppb[1] = parts per billion.

Metal	DEQ Acute Criteria (ppb[1])	DEQ Chronic Criteria (ppb[1])	# Above Criteria	% of Miles Above Criteria
Arsenic	340	150	0	0% (+/- 0%)
Cadmium	3.9 $CaCO_3$=100	1.1 $CaCO_3$=100	0	0% (+/- 0%)
Chromium	570 $CaCO_3$=100	74 $CaCO_3$=100	0	0% (+/- 0%)
Copper	13 $CaCO_3$=100	9 $CaCO_3$=100	0	0% (+/- 0%)
Lead	120 $CaCO_3$=100	14 $CaCO_3$=100	0	0% (+/- 0%)
Mercury	1.4	0.77	0	0% (+/- 0%)
Nickel	180 $CaCO_3$=100	20 $CaCO_3$=100	0	0% (+/- 0%)
Selenium	20	5	0	0% (+/- 0%)
Silver	3.4 $CaCO_3$=100	NA	0	0% (+/- 0%)
Zinc	120 $CaCO_3$=100	120 $CaCO_3$=100	0	0% (+/- 0%)

Sediment Metals

DEQ collected 492 sediment metals (arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, and zinc) samples from 2001 through 2012 and reported results in the 2008, 2010, 2012, and 2014 Integrated Reports. Sediment metals concentrations were below Probable Effects Concentrations (PECs) and affected a low percentage of stream miles. Due to the low prevalence of metals above PECs in Virginia's wadeable streams and high sampling costs, DEQ has suspended sediment metals sampling. Consequently DEQ will not report on sediment in the 2016 assessment cycle. Integrated Report chapters from previous assessment cycles contain estimates of sediment metals in sediment.

These chapters can be accessed at:
http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/ProbabilisticMonitoring.aspx#reports.

Organic Chemicals in Sediment

In 2001 and 2002, DEQ collected organic chemicals, organic pesticides, polychlorinated biphenyls, semi-volatile constituents, and herbicides in sediment but the data were not analyzed at a low enough detection limit to provide useful information. DEQ collected 209 organic chemical samples (total PCB, total PAH, heptachlor, chlordane, dieldrin, lindane, endrin, DDT, DDD, DDE, Total DDT, anthracene, chysene, fluoranthene, naphthalene, phenanthrene, pyrene, benzoanthracene, benzo-a-pyrene) in sediment samples from 2003 through 2006 and reported results in the 2008 and 2010 Integrated Reports Probabilistic Monitoring chapters. A low percentage of wadeable stream miles had concentrations above PECs. DEQ has suspended sampling for organic chemicals across all monitoring programs due to low concentrations and high sampling costs, and will not report on organic chemicals during this assessment cycle. Integrated report chapters from previous assessment cycles contain estimates of organic chemicals in sediment.

These chapters can be found online at:
http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/ProbabilisticMonitoring.aspx#reports.

Bacteria

Escherichia coli (E. coli) bacteria are found in the intestines and fecal matter of warm-blooded animals. High counts of E. coli bacteria in a stream indicate that there is an elevated risk of illness from

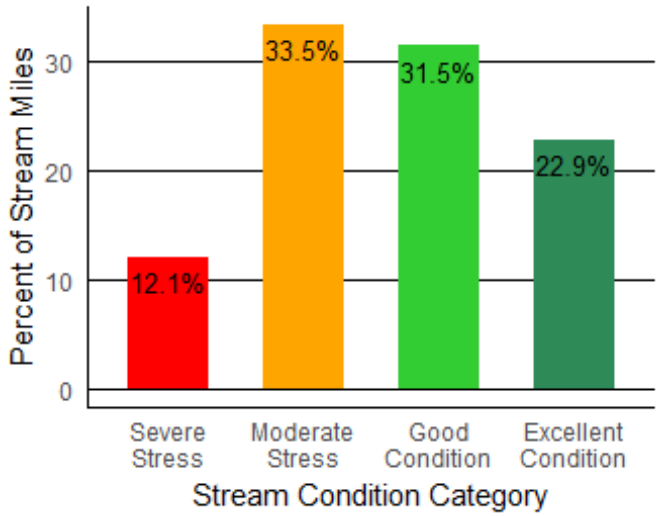
pathogenic organisms. According to Virginia's Water Quality Standard for E. coli, a stream should not exceed a geometric mean (for two or more samples taken within a calendar month) of 126 colony forming units (cfu) per 100mL of water or an instantaneous maximum of 235 cfu/100mL (Commonwealth of Virginia 2011).

DEQ bacterial impairment listing is determined based on a temporal data set where bimonthly bacteria samples are collected from a single site over two years. Bacteria are only sampled once at each ProbMon site. Site specific bacteria problems are best characterized by repeated samples over several months as is the approach in DEQ's ambient monitoring program. For this reason, bacteria results from the freshwater ProbMon program and ambient monitoring program are not comparable and as such the results are not presented.

Beginning in 2013, DEQ sampled bacteria monthly at probabilistic monitoring sites that met certain criteria. Monthly sampling efforts will allow DEQ to make temporally accurate bacteria estimates, which will be considered for inclusion in future reports.

Biological Monitoring

Biological monitoring, or biomonitoring, of streams and rivers is an integral component of DEQ's water quality monitoring program. Biomonitoring allows DEQ to assess the overall ecological condition of streams and rivers by evaluating stream condition with respect to suitability for support of aquatic communities. In Virginia, benthic macroinvertebrate communities are used as indicators of ecological condition and to address the question of whether a waterbody supports the aquatic life designated use.



DEQ uses multimetric macroinvertebrate indices, specifically the Virginia Stream Condition Index (VSCI) and the Virginia Coastal Plain Macroinvertebrate Index (VCPMI), to assess the aquatic life use status of wadeable streams and rivers. The VSCI and the VCPMI are applied to biomonitoring data collected in freshwater non-coastal areas and freshwater coastal areas, respectively. These indices utilize several biological metrics that are regionally calibrated to the appropriate reference condition (DEQa 2006; DEQ 2013). Results are calculated into a single value, or score, that is sensitive to a wide range of stressors.

Table 4.4-5. VSCI/CPMI (2009 - 2014, n=254) Scores compared to Virginia's Assessment thresholds.

Parameter	Below Standard
VSCI/VCPMI	45.6% (+/- 7.0%)

VSCI and VCPMI scores were scaled for comparability in all analyses. Based on VSCI and VCPMI ProbMon results, VADEQ estimates that 45.6% of Virginia streams and rivers do not meet the aquatic life use standard (Table 4.4-5). An estimate of statewide biological health by condition category is shown in Figure 4.4-5. VSCI scores less than 42 are considered severely ecologically stressed, scores between 42 and 60 are moderately stressed, while sites above 60 to 72 are thought to have good ecological conditionals and sites with VSCI scores above 72 are considered to have excellent water quality and habitat conditions (DEQ, 2006a). It is important to remember that biological indicators represent long-term water quality conditions and respond to all sources of stress.

Figure 4.4-5. Biological stream condition index based on VSCI/VCPMI Scores (2009 - 2014, n = 254).

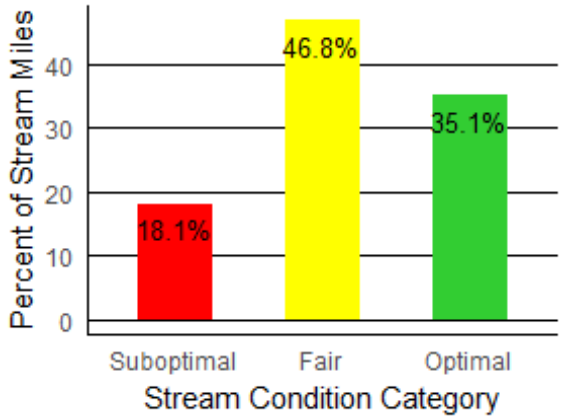
Parameters without Water Quality Standards

Stressors that increase the risk to benthic macroinvertebrate communities and do not have specific water quality standards include streambed sedimentation, habitat degradation, nutrients, ionic strength, and water column cumulative metals. Thresholds for the aforementioned stressors are presented in Tables 4.4-6 and 4.4-7 and are derived from literature values. The 'optimal' classification represents water quality conditions that are not associated with degraded aquatic communities. Stressors classified as 'suboptimal' increase the likelihood of finding an impacted aquatic community. The condition class between optimal and suboptimal is termed 'fair' as the stress to the aquatic community is less certain.

Table 4.4-6. Thresholds of condition classes for biological indicators.

Response Parameters	Optimal	Suboptimal	Classification Reference
Virginia Stream Condition Index	> 60	<50	(DEQ 2006a)
Virginia Coastal Plain Macoinvertebrate Index	> 40	<30	(DEQ 2013)

Table 4.4-7. Thresholds of condition classes for stressor indicators[1].



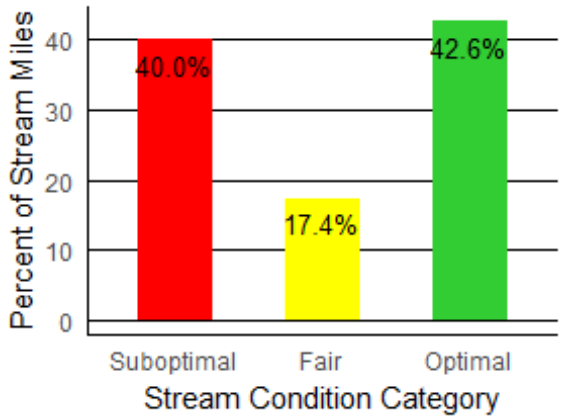
Stressor Parameters	Optimal	Suboptimal	Classification Reference
Total Nitrogen (mg/L)	< 1	> 2	(DEQ 2006a)
Total Phosphorus (mg/L)	< 0.02	> 0.05	(DEQ 2006a)
Habitat Degradation (unitless)	> 150	< 120	(USEPA 1999)
Streambed Sedimentation (unitless)	> -0.5	< -1.0	(Kaufmann 1999)
Ionic Strength (TDS mg/L)	< 100	> 350	(DEQ 2006b)
Cumulative Dissolved Metals (unitless)	< 1	> 2	(Clements 2000)

[1] The relative risk screening values presented in Tables 4.4-8 do not represent water quality criteria nor are they intended for establishing TMDL endpoints. The values represent an increase in the probability of stress to benthic communities.

Habitat Disturbance

Habitat is defined as the area or environment where an organism resides. It encompasses its surroundings, both living and non-living. Fish, aquatic insects, and plants require certain types of habitat to thrive, so in-stream and riparian (stream bank) habitat is evaluated when a biomonitoring sample is collected. Because different organisms have diverse habitat requirements, a variety of available habitat types in a stream or river will support a diverse aquatic community. Habitat is scored by evaluating ten habitat parameters and adding them together (total scores range from 0 to 200). Habitat scores above 150 indicate habitat conditions favorable for supporting a healthy aquatic community and are considered optimal. Scores lower than 120 are considered suboptimal and scores between 120 and 150 are fair (EPA 1999). As indicated in Figure 4.4-6, DEQ estimates that slightly over 35% of stream and river miles have available habitat that is considered optimal.

Figure 4.4-6. Estimate of Habitat Condition in Virginia Streams and Rivers. Data presented is from 2009 - 2014 (n = 254).



Streambed Sedimentation

Excessive sedimentation is a component of habitat and is one of the most pronounced impacts to benthic communities. Excess sediment fills interstitial spaces in the stream substrates used by aquatic organisms, disturbs refuge areas, and can potentially smother the organisms. Until recently, tools for quantifying sedimentation impacts in streams have been inadequate. Methods existed for describing dominant instream particle size, but it was difficult to differentiate between natural conditions and man-made problems. Virginia has a variety of stream types; many are naturally sand/silt bed streams, so simply measuring the size of the sediment particles cannot differentiate natural and human-influenced sediment load.

DEQ uses the relative bed stability (RBS) method for predicting the expected substrate size distribution for streams (Kaufmann 1999). RBS incorporates stream channel shape, slope, flow, and sediment supply. The method calculates a 'stream power' based on channel measurements to predict the expected sediment size distribution. The ratio of the observed sediment to the expected sediment is a measure of the RBS. A stream with a log RBS of less than -1 is carrying excess sediment while streams above -0.5 have a normal sediment load (Kaufmann 1999 and USEPA 2000). Nearly 40% of Virginia's stream and river miles are estimated to have suboptimal sedimentation values (Figure 4.4-7).

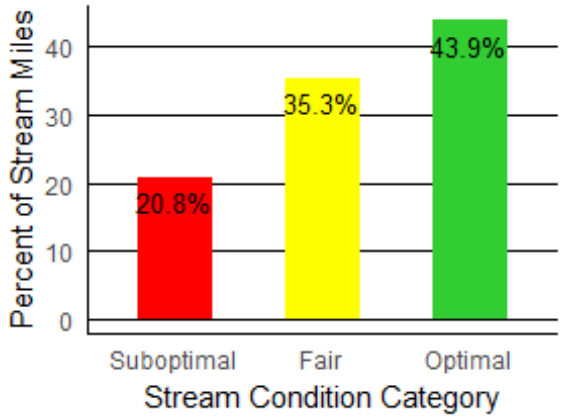
Figure 4.4-7. Estimate of streambed sedimentation conditions in Virginia streams and rivers as defined by LRBS measures. Data presented is from 2009 - 2014 (n = 231).

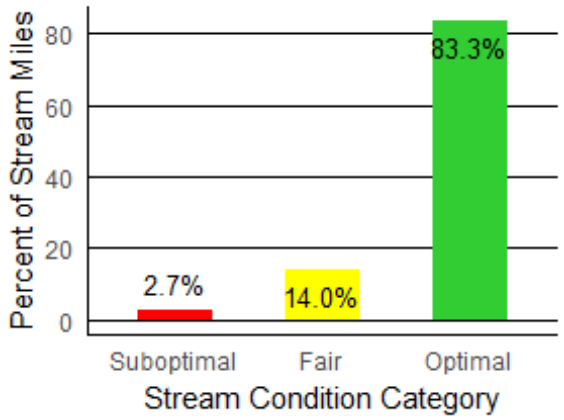
Nutrients

Nutrients are substances assimilated by living organisms that promote growth. Nitrogen and phosphorus are the two most important nutrients in Virginia streams and rivers. Excess nutrients can stimulate in-stream plant and algal growth. Characteristics of nutrient enriched streams may include low dissolved oxygen, frequent fish kills, shifts in aquatic communities, and blooms of nuisance algae. Nutrients may come from fertilized lawns and cropland, failing septic systems, municipal and industrial discharges, and/or livestock manure.

Total phosphorus above 0.05 mg/L and total nitrogen above 2 mg/L is considered suboptimal (Table 4.4-7) and can result in undesirable algae growth and shifts in aquatic communities (DEQ 2006a). DEQ estimates that nearly 44% and over 83% of stream and river miles are classified as optimal for total phosphorus and total nitrogen, respectively (Figures 4.4-8 and 4.4-9).

Figure 4.4-8. Estimate of Total Phosphorus Conditions in Virginia Streams and Rivers. Data presented is from 2009 - 2014.





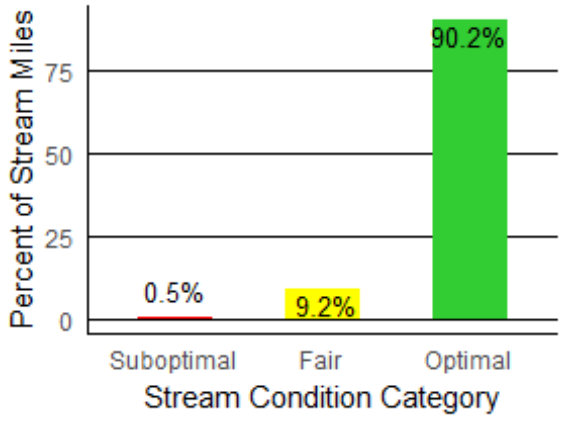


Figure 4.4-9. Estimate of Total Nitrogen Conditions in Virginia Streams and Rivers. Data presented is from 2009 - 2014.

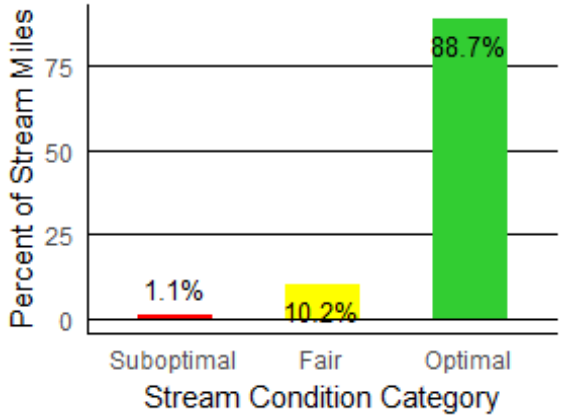
Ionic Strength (Total Dissolved Solids)

Ionic strength varies with natural geology, but increases significantly in response to anthropogenic activities such as surface mining, road salts, or other industrial discharges. DEQ uses total dissolved solids (TDS) to measure ionic strength. Ionic strength is a measure of dissolved ions, dissolved metals, minerals, and organic matter in the water column. Water quality studies have consistently demonstrated that high levels of TDS in the water column impact aquatic life (DEQ 2006b). TDS levels above 350 mg/L increase the likelihood of having a degraded aquatic community and are considered suboptimal (Table 4.4-7). Results are shown in Figure 4.4-10; DEQ estimates that about 0.5% of Virginia streams have TDS levels in the suboptimal range.

Figure 4.4-10. Estimate of Ionic Strength Conditions in Virginia Streams and Rivers. Data presented is from 2009 - 2014.



Cumulative Dissolved Metals (Cumulative Criterion Unit Metals Index)

Heavy metals such as mercury, chromium, cadmium, arsenic and lead in streams and rivers can be harmful to aquatic insects at low concentrations. The metals tend to accumulate in the gills and muscles of aquatic organisms. Dissolved metals have been identified as important predictors of stream health. Toxicity of many metals is dependent on water hardness, making it necessary to calculate site specific water quality criteria from hardness values.

In the context of water quality criteria, dissolved metals are typically treated independently (as discussed in Section 4.4.3); however there is strong evidence that metals have a cumulative effect (Clements 2000). Cumulative Criterion Units (CCU) account for this additive effect by standardizing each dissolved metal's concentration. The metals are summed together and the result is the CCU Metals Index score. When the CCU Metals Index is above 2, the cumulative effect is considered likely to harm aquatic life (Clements 2000). DEQ estimates that around 1% of river miles in Virginia have Cumulative Criterion Units that are considered suboptimal (Figure 4.4-11; Table 4.4-7).

Figure 4.4-11. Estimate of Cumulative Criterion Unit Metals Index in Virginia Streams and Rivers. Data presented is from 2009 - 2014.

Stressor Extent and Relative Risks

One of the advantages of probabilistic datasets is the ability to calculate the stressor extent (Figure 4.4-12, Figure 4.4-14), and relative risks (Figure 4.4-13) that different environmental stressors have on the ecological health of rivers and streams across large regions. Since the stations are selected at random, DEQ can estimate water quality parameter values over the entire state with known confidence. USEPA and other states have employed stressor extent and relative risk concepts extensively in their reports (ODEQ 2007; USEPA 2006; Van Sickle 2006; Van Sickle 2008).

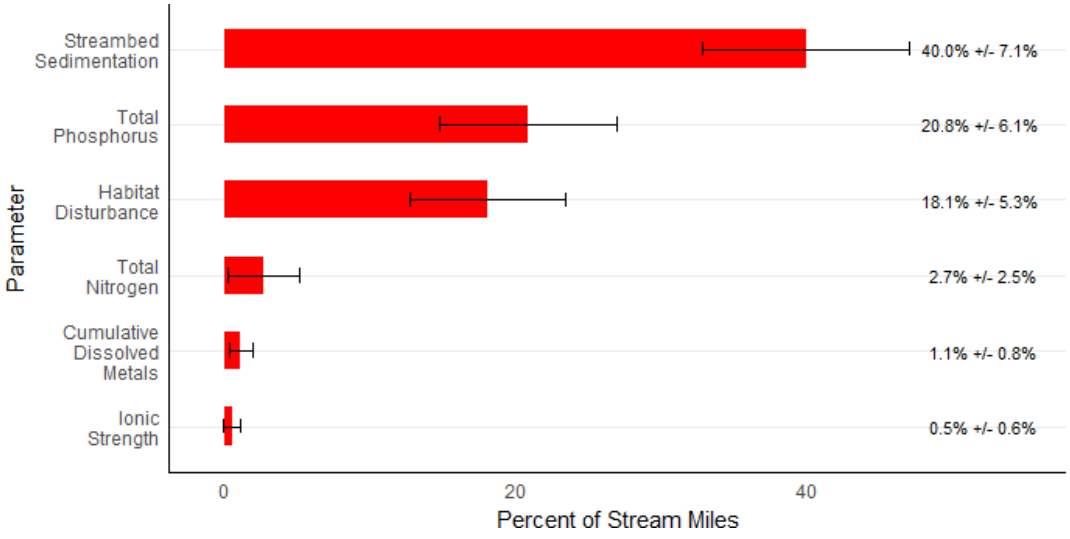
Stressor extent shows how prevalent a stressor is in Virginia streams. Calculation of relative risk requires classification of water quality responses (e.g. the benthic macroinvertebrate indices – Table 4.4-6) and the water quality stressors (Table 4.4-7) into optimal and suboptimal categories. DEQ classified biological response parameters based on the aquatic life use standard. The stressor indicators in Table 4.4-7 were classified using screening values from peer reviewed literature studies. It is important to remember that the stressor screening values are not equivalent to water quality standards in the Commonwealth of Virginia. This data-intensive statistical technique requires the entire probabilistic monitoring dataset (2001 - 2014).

Relative risk is a term borrowed from the medical field and applied here to communicate the severity of impact a stressor has on the aquatic environment. For example, it has been shown that an individual with total cholesterol above 240 mg/dl is at greater risk for heart disease than an individual whose cholesterol is below 200 mg/dl. When an individual has a cholesterol level above 240, their relative risk of having heart disease is higher than an individual with cholesterol level below 200.

The relative risks for aquatic stressors can be interpreted in a similar manner to the heart disease example. Figure 4.4-13 illustrates that the relative risk to the biological community due to habitat disturbance is 4.8; thus, the biological community is 4.8 times more likely to be considered suboptimal when habitat disturbance scores (USEPA 1999) are below 120. Relative risk values larger than 1 indicate an elevated risk to the biological community; consequently, only water quality stressors with a relative risk

greater than 1 are reported in this chapter. Sediment metals and pH were also evaluated for increased risk to the biological community, but did not show significant relative risk to the biological community.

Figure 4.4-12. Stressor extent for major benthic macroinvertebrate stressors in Virginia streams. The horizontal lines associated with the parameters illustrate the confidence intervals. Stressor extent shows the frequency of the stressor in all Virginia streams from data collected for the 2016 Integrated Report (2009 - 2014).



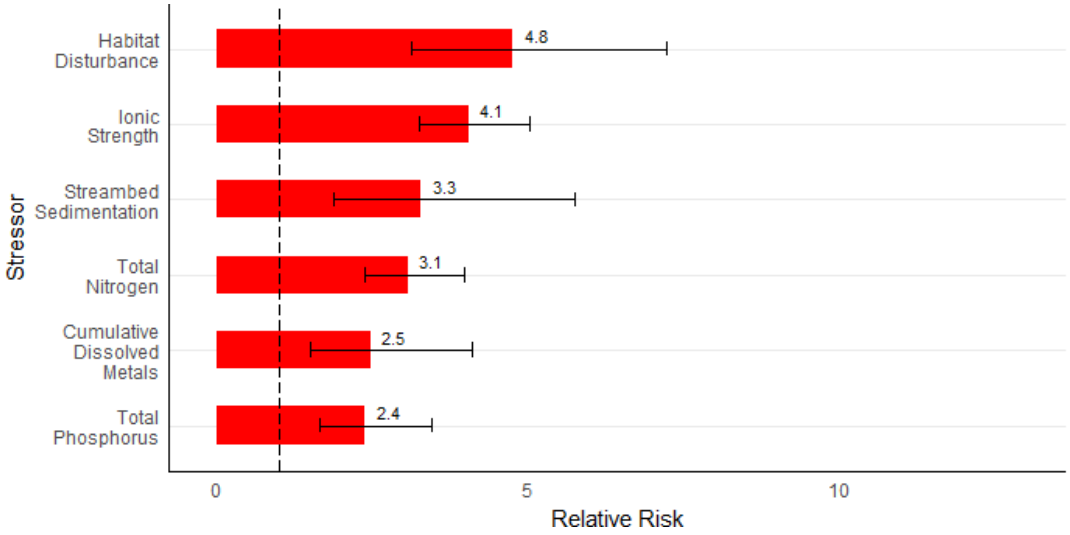


Figure 4.4-13. Relative Risk for major benthic macroinvertebrate stressors in all Virginia streams. The horizontal lines associated with the parameters illustrate the confidence intervals. The vertical dashed line at 1 indicates significance; thus, all relative risk estimates and confidence intervals that exceed the dashed vertical are significant. Relative risk shows the number of times more likely a benthic macroinvertebrate community is to be scored in the suboptimal range if the parameter shown on the y-axis is degraded.

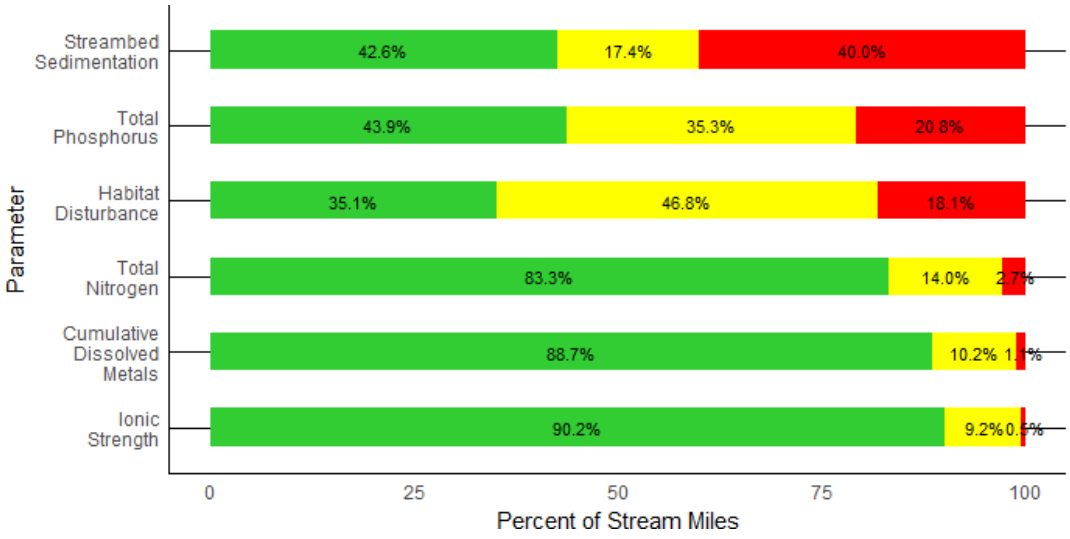

The most common stressor across Virginia is streambed sedimentation. ProbMon data estimates streambed sedimentation is considered suboptimal in almost 40% of Virginia streams. When streambed sedimentation levels are suboptimal, relative risk analysis predicts they are 3.3 times more likely to have suboptimal benthic community than streams with optimal sedimentation levels. Nearly 18% of Virginia

streams have suboptimal habitat disturbance scores; suboptimal habitat disturbance scores increase the relative risk of a suboptimal aquatic community by a factor of 4.8.

The two major nutrients found in Virginia streams are nitrogen and phosphorus; their relative risks are 2.4 and 3.1, respectively. Suboptimal phosphorus conditions occur in many more streams (20.8%) than elevated nitrogen (2.7%). Ionic strength (as measured by total dissolved solids) has a relative risk of 4.1 which is one of the highest relative risks in the analyses. However, suboptimal ionic strength conditions were only found in 0.5% of Virginia streams. Dissolved metal concentrations that may cause adverse biological condition were found in 1.1% of Virginia streams; however, elevated dissolved metal concentrations increase the relative risk of having a suboptimal benthic macroinvertebrate community by 2.5.

Stressor extent presented in Figure 4.4-12 only focuses on the percent of stream miles deemed suboptimal by each of the major stressors to Virginia streams. Figure 4.4-14 encompasses the entire stream population for each stressor to relate a more complete narrative surrounding stressor extents in Virginia. Streambed sedimentation has the highest extent of stress in Virginia and nearly the same percent of stream miles in the optimal and suboptimal categories. As we have explored through previous visualization tools, streambed sedimentation, total phosphorus, and habitat disturbance are fairly widespread stressors statewide. Total nitrogen, water column metals, and ionic strength are fairly rare in Virginia with the majority of stream miles in the optimum category of their respective parameter.

Figure 4.4-14. Stressor extent for major benthic macroinvertebrate stressors in all Virginia streams (2009 - 2014) showing all condition classes (optimal, fair, and suboptimal). Optimal condition estimates are shown in green, fair condition estimates are yellow, and suboptimal conditions are shown in red.

Uses of Probabilistic Data

In addition to estimating the condition of all streams and rivers compared to established water quality criteria/screening values and identifying the major stressors to aquatic organisms, freshwater ProbMon data has many ancillary applications within water quality management programs. Examples of these uses are discussed below.

ProbMon data is used in describing both the natural and baseline conditions of Virginia streams. In addition, ProbMon has helped identify minimally disturbed streams and understand their natural variability. This information is integral for DEQ to develop more regionally specific water quality expectations and in turn define reference conditions and select appropriate reference sites. ProbMon has

also provided statistically defensible descriptions of stream conditions as of the beginning of this century. DEQ will find this baseline tremendously valuable for comparison in future assessments.

ProbMon data is currently being used by an internal DEQ workgroup tasked with improving the stressor analysis process in benthic macroinvertebrate TMDLs. Stressor analysis is the process whereby candidate causes of stress (or stressors) to benthic macroinvertebrate communities are evaluated. The purpose of the workgroup is to develop data collection recommendations and scientifically defensible screening values for categorizing potential stressors. ProbMon data is especially useful in describing statewide in-stream conditions for those parameters that do not currently have water quality standards. Understanding existing conditions for those parameters without water quality standards provides perspective on parameter data and a way to evaluate potential stressors. Relative Bed Stability and metals in water column CCU are examples of new tools that are applicable to benthic macroinvertebrate TMDL stressor analysis. Relative Bed Stability is currently being utilized to evaluate sedimentation as a candidate stressor. ProbMon data is being used to create stressor specific metrics to help TMDL staff identify stressor signals from impaired reaches and collect the appropriate water chemistry information.

The collocation of biological, chemical, habitat and landuse data at ProbMon sites also allows for the examination of multiple stressors such as dissolved metal CCUs. DEQ plans to explore the effects of multiple stressors in future reports. This information should aid TMDL development and provide insight into how biological communities and stressor parameters interact.

ProbMon data is also being used as a test platform for new monitoring approaches such as periphyton and fish community data collection. The collection methodology was designed and tested in tandem with the USEPA's National Aquatic Resource Survey (NARS). Until DEQ participated in the NARS sampling, habitat and biology data collection methodologies were not refined for large rivers. Now DEQ is collecting complete ProbMon data sets for large rivers and plans to report on the condition of this valuable freshwater resource. Because ProbMon provides biological, chemical, physical habitat, and land use information at each site, the data set is indispensable for developing and improving biomonitoring tools.

The ProbMon dataset provided crucial data needed to fill in gaps during the development of the VSCI and the validation of both the VSCI and Coastal Plain Macroinvertebrate Index (CPMI) (Maxted 2000). Following the validation, VSCI assessment results were included in the 2008 Integrated Report. DEQ used ProbMon data to validate the CPMI. Specifically, ProbMon data was utilized to identify new reference sites in the coastal plain, check ecoregion best standard values, and select potential metrics that would help the CPMI detect benthic macroinvertebrate community stresses created by human activity. The effort resulted in a new, robust tool for evaluating benthic macroinvertebrate communities in the coastal plain regions of the Commonwealth called the Virginia Coastal Plain Macroinvertebrate Index (VCPMI, DEQ 2013). The technical VCPMI document is online at: http://www.deq.virginia.gov/Portals/0/DEQ/Water/WaterQualityMonitoring/ProbabilisticMonitoring/vcpmi.pdf. ProbMon also aided in improving the biomonitoring program by identifying over 100 new biological references sites, doubling the number of reference sites in the Virginia reference site database.

ProbMon sites are the platform for building a genus-level macroinvertebrate database which may ultimately be used in developing a more robust multimetric assessment tool. ProbMon data may also be used to create a biological condition gradient for Virginia stream and rivers. The biological condition gradient is a descriptive model that illustrates how increasing stress alters ecological attributes (Davies and Jackson 2006). A biological condition gradient defines expected conditions, like benthic macroinvertebrate community structure, for streams by stream order and ecoregion. The biological condition gradient may help DEQ protect high-quality streams and provide stepwise interim goals for tracking water quality improvement.

The potential use of probabilistic data to support water quality permitting decisions is currently being evaluated and a workgroup has been formed to explore this possibility.

An important future application of ProbMon data is change analysis (Kincaid 2016). DEQ adjusted the experimental design of ProbMon by adding randomly selected sentinel sites in order to accelerate its

ability to detect changes in population estimates. By revisiting a relatively small number of these randomly located sites each year, DEQ will be able to detect statewide and regional chemical, habitat, and biological changes. Perhaps the most important question a monitoring program addresses is: are management initiatives effective? The ability of ProbMon to detect shifts in population estimates is critical to the goal of assessing the effectiveness of water quality management programs on a statistically rigorous statewide scale.

Conclusion

DEQ analyzed 14 water quality parameters with established water quality criteria and/or screening values and 6 parameters without water quality criteria. Most of the parameters that have water quality criteria meet applicable standards. The majority of water quality standard exceedences are attributed to legacy pollutants or natural conditions. The results presented in the ProbMon chapter reflect the success of DEQ's management of water quality parameters with water quality criteria.

Only biological monitoring results were found to be below screening thresholds in a relatively high percentage of streams. Benthic macroinvertebrate communities were degraded in 43.9% of the wadeable streams and rivers in Virginia; a percentage that could be considered widespread. Benthic macroinvertebrate communities are indicators of water quality problems because they respond to a variety of water quality stressors including parameters that have water quality standards (e.g. dissolved oxygen levels) and parameters that do not have criteria (e.g. such as nutrients and sedimentation). The following six stressors increase the risk to aquatic organisms and do not currently have water quality standards: streambed sedimentation, habitat disturbance, total phosphorus, total nitrogen, total dissolved solids, and cumulative metals in water column. These parameters are discussed in Section 4.4.5. While these six major stressors do not currently have water quality standards, most are being addressed through a variety of strategies such as permits, TMDLs, nutrient management plans and best management practices. As the ProbMon program evolves and DEQ expands on the uses of ProbMon data, enhancement of the strategies for understanding, evaluating and restoring the Commonwealth's streams and rivers will continue.

Presentations, posters, reports, and handouts about ProbMon are available for viewing and download at the following website:

CHAPTER 4.5 ESTUARINE PROBABILISTIC MONITORING RESULTS

Introduction

Each year, DEQ's Estuarine Probabilistic Monitoring Program[1] collects samples at 50 estuarine sites, randomly selected by computer from designated non-oceanic tidal waters. Designated waters include the narrow upper tidal reaches (transitional and tidal freshwaters), tidal tributaries and embayments of the James, York, Rappahannock and Potomac Rivers. Tidal tributaries and embayments of Coastal Delmarva and the Back Bay – North Landing River region are also included.[2] In the state design, the only preference applied in the process of selection is the requirement that 70% (N = 35) of the annual sites be from inland tidal waters of the Chesapeake Bay and North Landing River watersheds, and 30% (N = 15) of the sites be from the coastal Delmarva peninsula and Back Bay. At five-year intervals (2010, 2015, 2020, etc.) DEQ's Estuarine ProbMon Program is integrated with the National Aquatic Resources Survey (NARS) / National Coastal Condition Assessment (NCCA) Program, the design of which may include a varying number of sites within the Chesapeake, James, York and Rappahannock mainstems. The number of Virginia estuarine sites selected for NARS surveys varies from cycle to cycle, but is usually between 20 and 25. During NCCA years, DEQ complements the national design with enough stations from the state design to complete a total of 50 sites, although the exact 70% / 30% division between inland and coastal tidal waters may not be maintained.

The six-year assessment window (2009 – 2014) encompassed by the 2016 Integrated Report (IR or Report) includes 273 sets of estuarine samples collected from 273 sites. The sliding, six-year assessment windows included in sequential Reports result in considerable overlap in the monitoring data included. Approximately 67% of the data included in each IR were also assessed and included in the previous Report. Consequently, most of the following sections have changed little from those in the 2014 IR.

The geographic distribution and salinities of the 273 probabilistic estuarine sites visited during the six-year period are illustrated in the map of Figure 4.5-1. The salinities classified here represent the near-bottom salinities at the time of sampling, associated with the contemporary benthic community samples collected at the same sites. The color-coded symbols on the map indicate the salinity zone of each site, as summarized in Table 4.5-1 below. The percentages and confidence intervals listed in the table represent the percentages among the 273 sites with measured salinity values, and are not representative of Virginia's estuarine waters as a whole. If the area of the entire Chesapeake Bay mainstem and the lower tidal portions of the James, York, and Rappahannock Rivers were to be included in the Commonwealth's sampling design, the tidal freshwater and oligohaline percentages would be much reduced, and the saltwater percentage would be much greater. All 50 euhaline sites (salinity > 30.0‰) were located adjacent to oceanic waters along the Delmarva coast.

[1] A more detailed description of probabilistic monitoring can be found on the DEQ Webpages at: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/ProbabilisticMonitoring.aspx

[2] The Chesapeake Bay mainstem and the broad tidal tributary mainstems of the lower James, York and Rappahannock Rivers are excluded from the state designation because they are sufficiently characterized by the Chesapeake Bay Tidal Water Quality Monitoring and Assessment Program.

Table 4.5-1 Numbers and Proportions of Estuarine ProbMon Sites Occurring in Various Salinity Zones.

Salinity Class	Salinity Range (ppt)	Stations	Percentage	
TF - Tidal Freshwater	< 0.5 ‰	30	10.99 ± 3.73%	Fresh and Transitional 64 (23.44 ± 5.05%)
OH - Oligohaline - Transitional	0.5 - 5.0 ‰	34	12.45 ± 3.43%	
MH - Mesohaline	> 5.0 - 18.0 ‰	85	31.14 ± 5.52%	Saltwater 209 (76.56 ± 5.05%)
PH - Polyhaline	>18.0 - 30.0 ‰	74	27.11 ± 5.30%	
UH - Euhaline	> 30.0 ‰	50	18.32 ± 4.61%	

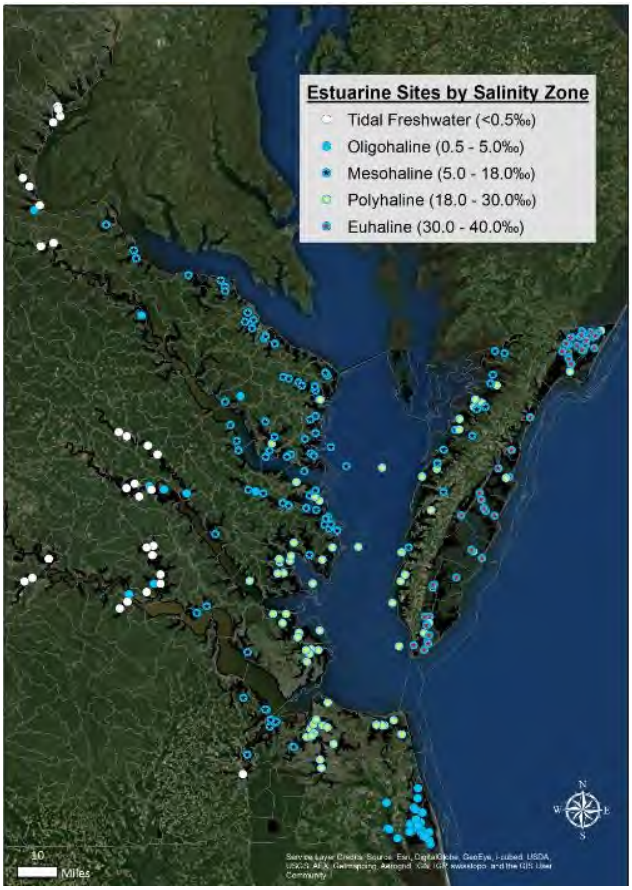

Figure 4.5-1 Geographic distribution of the 273 Estuarine ProbMon Sites Sampled in Tidal Virginia Waters between 2009 and 2014, with their Respective Salinity Zones.

Parameters Measured and Results

DEQ's Estuarine ProbMon Program adheres closely to the same selection of water quality and sediment quality parameters as identified in the national (NCCA) program. Water Quality, Sediment Quality and Benthic data are collected at each of the probmon sites. It's important to note that the water quality parameters (*e.g.*, nutrients, bacteria, dissolved metals, DO, temperature, pH, *etc*.) that are measured at probabilistic sites are considered to be isolated instantaneous observations and are insufficient for assessment purposes because the intensity and duration of such stressors are unknown. However, sediment chemistry, sediment toxicity, and benthic community wellbeing results are used to conduct Weight-of-Evidence assessments at each individual site for Aquatic Life Use (ALU). All three of these measures are considered to be temporally integrative, providing an assessment of environmental conditions experienced by the benthic community during the period prior to the time of sampling. The results of water quality, sediment quality and benthic data are summarized below.

Water Quality

The NCCA Program has traditionally[3] used five parameters to characterize estuarine water quality: near-surface (1) dissolved inorganic Nitrogen (mg/L DIN), (2) dissolved inorganic Phosphorus (mg/L DIP), and (3) chlorophyll-a (µg/L Chl-a), plus (4) water clarity, expressed as the percent of available PAR reaching a specified 1.0 meter depth, and (5) near-bottom dissolved Oxygen (mg/L DO). A classification ("Good", "Fair", or "Poor") based on each of these parameters was subsequently integrated into an overall Water Quality Index (WQI) characterization for the site. The observed values of several of these same parameters are also included for consideration in site-specific weight-of-evidence assessments for the aquatic life designated use (ALU) to be discussed later in this chapter.

On a national scale, the threshold concentrations of these five parameters, differentiating among "Good", "Fair", and "Poor" water quality classes, vary regionally. The final thresholds that were applied for evaluation of individual sites in the 2015 NCCA Report V are summarized in Table 4.5-2a, below. Guidelines for characterizing restricted regions or areas based on their distributions of individual site scores are summarized in Table 4.5-2b. The following discussion of water quality in Virginia's estuaries is based primarily on these thresholds, except where specifically indicated otherwise.

Table 4.5-2a National Coastal Condition Report Water Quality Indicators and Site Specific Thresholds for the Northeast Coastal Region (USEPA 2016)**.**

Estuarine Water Quality Thresholds				
	Region	Good	Fair	Poor
Surface Concentrations of Dissolved Inorganic Nitrogen (DIN) in Estuaries	Northeast Region	< 0.1 mg/L	0.1 - 0.5 mg/L	> 0.5 mg/L
Surface Concentrations of Dissolved Inorganic Phosphorus (DIP) in Estuaries	Northeast Region	< 0.01 mg/L	0.01 - 0.05 mg/L	> 0.05 mg/L
Surface Concentrations of Chlorophyll a in Estuaries	Northeast Region	< 5.0 µg/L	5.0 - 20.0 µg/L	> 20 µg/L
Water Clarity (percent of photosynthetically active radiation [PAR] available at a depth of 1.0 meters) in Estuaries	Waters with naturally high turbidity	> 10%	5 - 10%	< 5%
	Waters with normal turbidity	> 20%	10 - 20%	< 10%
	Waters that support SAV	> 40%	20 - 40%	< 20%
Bottom Water Concentrations of Dissolved Oxygen in Estuaries	All Regions	> 5.0 mg/L	2.0 - 5.0 mg/L	< 2.0 mg/L

[3] NCC Reports I - V, USEPA, 2001, 2004, 2008, 2012, 2015

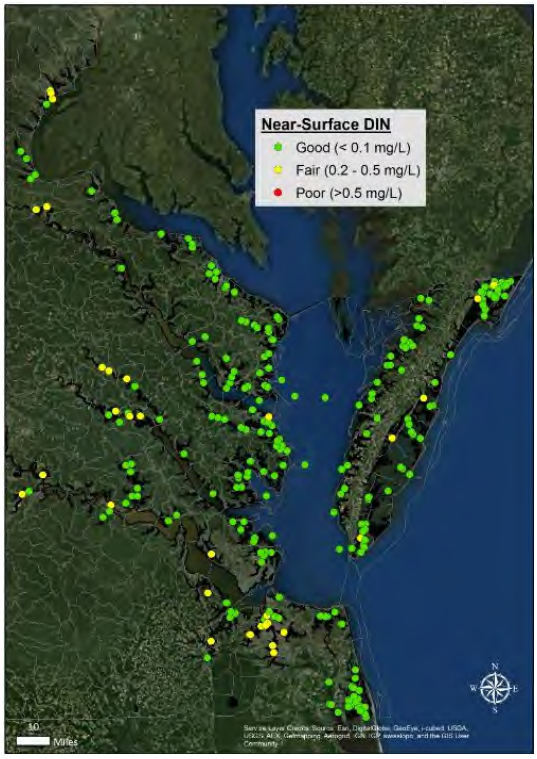

Table 4.5-2b Guidelines for Characterizing Regions Based on the Distributions of Individual Site Scores. (USEPA 2016)

Regional Rating	Cutpoints
Good	Less than ten percent of the coastal area is in "Poor" Condition, and more than 50 percent of the coastal area is in "Good" condition.
Fair	Ten to 20 percent of the coastal area is in "Poor" condition, or 50 percent or less of the coastal area is in "Good condition.
Poor	More than 20 percent of the coastal area is in "Poor" condition.

Near-Surface Dissolved Inorganic Nitrogen (DIN): Concentrations of near-surface dissolved inorganic Nitrogen were measured in samples from 273 sites. DIN was calculated as the sum of the concentrations of dissolved nitrate (NO_3^-), dissolved nitrite (NO_2^-) and dissolved ammonium (NH_4^+) ions. Among the 273 samples, 240 (87.91 ± 3.88%) were classified as "Good" for DIN, 33 (12.09 ± 3.88%) were classified as "Fair", and zero were classified as "Poor".

The map presented in Figure 4.5-2 illustrates the geographic distribution of the 273 sites evaluated, classified, and color coded by their near-surface dissolved inorganic nitrogen concentrations. Virginia's estuaries would earn an overall rating of "Good" because the proportion of Good site characterizations was well above 50% and there were no sites characterized as Poor.

DIN Class	Range	Stations	Percentage
Good	< 0.1 mg/L	240	87.91 ± 3.88%
Fair	0.1 - 0.5 mg/L	33	12.09 ± 3.88%
Poor	> 0.5 mg/L	0	0.00%
Missing	N/A	0	0.00%
	Total	273	100.00%

Final 2016

Near-Surface Dissolved Inorganic Phosphorus (DIP): Near-surface dissolved inorganic Phosphorus (also known as phosphate - PO_4^{-3}, orthophosphate, or soluble reactive phosphorus - SRP) concentrations were also measured in samples from 273 sites. The geographic and statistical distributions of DIP characterizations are illustrated in the map and graphs of Figure 4.5-3. One hundred thirty-two (48.35 ± 5.95%) of the 273 samples were classified as "Good," 122 (44.69 ± 5.92%) were classified as "Fair", and 19 (6.95 ± 3.03%) were classified as "Poor."

Virginia's estuaries earn an overall "Fair" classification for DIP in regional waters, since less than 10% of sites scored "Poor" and 48.35% of the sites scored "Good". The threshold for a "Good" regional rating is 50%. The Elizabeth River system would be scored as "Poor" on a more limited regional basis.

DIP Class	Range	Stations	Percentage
Good	< 0.01 mg/L	132	48.35 ± 5.95%
Fair	0.01 - 0.05 mg/L	122	44.69 ± 5.92%

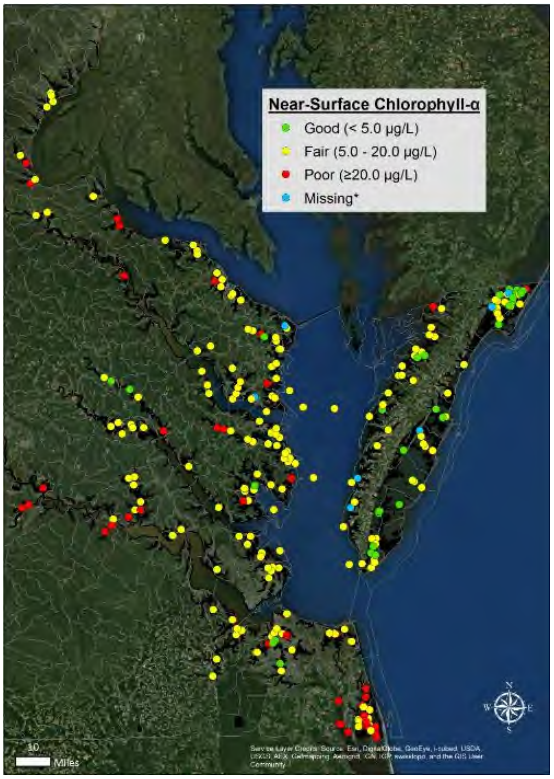

Figure 4.5-3 Geographic and Statistical Distributions and Characterizations of 273 Probabilistic Sites based upon Near-Surface Dissolved Inorganic Phosphorus (DIP) Concentrations (2009 – 2014).

Near-surface Chlorophyll-a: Chlorophyll-a (Chl-a) is used as an indirect measure of the quantity of phytoplankton (algae) in the water column. High values of chlorophyll-a, characteristic of excessive numbers of phytoplankton, are generally interpreted to result from nutrient enrichment or eutrophication of the associated water body.

Near-surface chlorophyll-a concentrations were analyzed from 266 of 273 samples from probabilistic estuarine sites (completeness = 97.44%). The missing seven samples (2.56 ± 1.88%) were mostly lost in the laboratory when their glass extraction tubes broke during centrifugation. On occasion, field-filtered Chl-a samples were rejected by the laboratory if they appeared to be contaminated (*e.g.*, if water had leaked into the filter container). Of the total 273 samples collected, 34 (12.45 ± 3.93%) were characterized as "Good" (< 5.0 µg/L Chl-a) using the chlorophyll-a thresholds in Table 4.5-2a, 191 sites (69.96 ± 5.46%) were classified as "Fair" and 41 (15.02 ± 4.26%) were classified as "Poor" (>20.0 µg/L Chl-a). The geographic, numerical, and statistical distributions of sites by chlorophyll-a class and the corresponding class thresholds are summarized in the map and tables of Figure 4.5-4.

Based on the NCCA thresholds for regional characterizations, Virginia's estuarine waters would receive an overall score of "Fair" for chlorophyll-a (less than 20% of sites score "Poor" and less than 50% score "Good"). The Chesapeake Bay mainstem and coastal Delmarva waters would also receive localized ratings of "Fair". Locally restricted tidal fresh and oligohaline waters of minor tributaries would be characterized as "Poor".

Chlorophyll Class	Range	Stations	Percentage
Good	< 5.0 µg/L	34	12.45 ± 3.93%
Fair	5.0 - 20.0 µg/L	191	69.96 ± 5.46%
Poor	≥ 20.0 µg/L	41	15.02 ± 4.26%

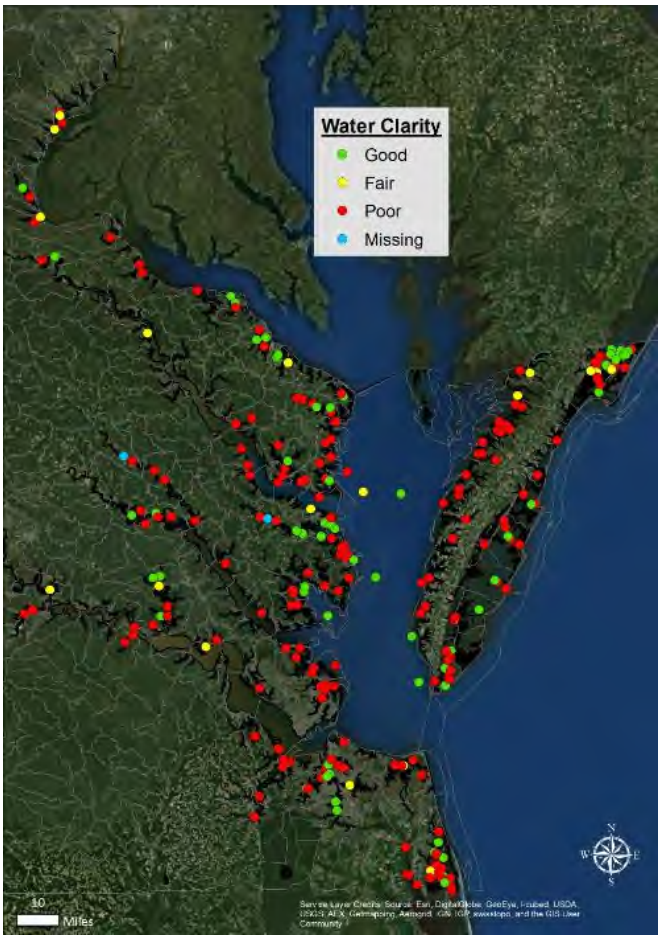
Water Clarity: Water clarity is considered an important element of water quality, but its inclusion in an integrated Water Quality Index (WQI) is somewhat complex. Part of this complexity stems from assigning thresholds to a very broad classification of coastal waters. Coastal waters are categorized as follows: (1) coastal waters with naturally high turbidity (Alabama, Louisiana, Mississippi, South Carolina, Georgia, and Delaware Bay), (2) coastal waters with normal turbidity (most of the United States), and (3) coastal waters that support SAV beds or have active programs for SAV restoration (Laguna Madre; the Big Bend region of Florida; the region from Tampa Bay to Florida Bay; the Indian River Lagoon; portions of Chesapeake Bay; Hawaii; American Samoa; Guam; Puerto Rico; and the U.S. Virgin Islands) (USEPA, 2012). The rationale for classifying such broad geographic areas into a uniform or homogeneous expectation of water clarity is open to question. Clearly, the expectation of water clarity and the presence or absence of SAV would not be the same for local areas with disparate depths, exposure to high wave activity, with strong tidal currents, areas of varying bottom substrates, or in estuaries fed by tannin-stained blackwater streams. Shallower waters, more subject to wind and wave action and the re-suspension of bottom sediment, would be expected to have higher turbidities (lower clarity) than deeper nearby waters.

Water clarity is also a function of the density of phytoplankton in the water column, and in this sense is a redundant characteristic that may be highly and inversely correlated with chlorophyll and nutrient concentrations in the water column. Its accurate measurement is also susceptible to variations in ambient light conditions – diffused light on cloudy or overcast days versus direct sunlight, and the angle of incident light at the water's surface. In addition, water clarity is extremely difficult to measure accurately at shallow sites.



EPA's Chesapeake Bay Program (CBP) has defined SAV zones for numerous segments within the Bay watershed as that portion of the segment extending from the shoreline out to a depth contour (isobath) of 2.0 meters, relative to mean low water (MLW) level, excluding certain segments where SAV was not expected to grow (Kemp et al., 2000). Water quality criteria (e.g., water clarity) related to SAV growth and survival are only applied within these defined areas and during defined seasons. "For several SAV species (notably Myriophyllum spicatum and Hydrilla verticillata), maximum depth penetration might be greater than two meters, but it was felt that this would be an exception…" (Kemp et al., 2000). Criteria for excluding certain areas from the maps were based primarily on known historical SAV distributions, and on habitat areas exposed to high wave energy and/or that have undergone physical modifications that prevented them from supporting SAV growth. Ironically, the same shallow water areas that potentially support SAV are the most susceptible to shoreline erosion and to the re-suspension of sediment by wave action. The presence of SAV in such shallow areas improves water clarity (and consequently water quality) by buffering wave action, thus enhancing the precipitation of suspended material, and reducing shoreline erosion and the re-suspension of previously deposited sediment. SAV and water clarity consequently interact with a positive feedback mechanism – the presence of SAV improves water clarity, improved water clarity enhances the growth of SAV, etc.

The water clarity criteria established by the CBP for areas of SAV within Virginia's Chesapeake Bay watershed are published in Virginia's Water Quality Standards 9VAC25-260-185. In the following characterization, the scientifically derived CBP light availability (clarity) habitat types have been extended geographically, equated with local habitat types, and integrated with NCCA criteria where appropriate. This provided the application of similar criteria to define potential SAV areas in estuarine waters of coastal Delmarva and to the oligohaline waters of the Back Bay / North Landing River region (tributaries to Currituck Sound, NC) as were applied within the Chesapeake Bay watershed. Within the Bay watershed, sites that were within the designated SAV areas and had a depth equal to or less than 2.0 meters at the time of sampling were evaluated using the CBP criteria for defined SAV areas. Elsewhere, sites with depths less than or equal to 2.0 meters were considered potential SAV areas and were evaluated with the NCCA SAV criteria, unless they were impacted by strong wave action or strong tidal currents. Such determinations were made using map reconnaissance, comments from site field sheets, and the evaluation of substrate structure. Sandy substrates with very low fine particle concentrations (*e.g.*, ≥ 95% sand) were considered to be characteristic of such impacted sites. Sites with deeper waters (>2.0 m) were evaluated as areas of normal turbidity, although why coastal Delmarva waters of Virginia should be

considered less turbid (normal) than coastal South Carolina and Georgia waters (naturally high) is a valid and unanswered question.

The geographic distribution and characterization of the 273 sites, based on the integrated, mixed water clarity criteria described above, are illustrated in the map of Figure 4.5-5. The statistical distribution of "Percent PAR @ 1.0 m depth" in the table of Figure 4.5-5 is not classified or color-coded because thresholds for characterizations ("Good", "Fair", "Poor") vary with location, salinity, depth, etc. The majority of the highest water clarity sites occur in the Chesapeake Bay mainstem and its larger embayments.

Virginia's estuarine waters received an overall score of "Poor" for water clarity because more than 20% of the individual sites were scored as "Poor". This score may be worse than warranted, because many sites that were individually scored as "Poor" actually fell within CBP SAV segments that, based on several years of ambient monitoring, were evaluated as meeting SAV growth goals for DEQ's 2014 Integrated Report (DEQ-WQA. 2014). This was especially evident in the upper tidal Potomac River, the Rappahannock, Mattaponi and Pamunkey Rivers, and tributaries to the lower tidal James River (refer to Figure 4.5-5). An additional factor is that DEQ's state probabilistic design targets smaller tributaries and embayments (generally shallower waters) where sediment laden storm runoff waters are more prevalent and re-suspension of existing sediment is more common, and the program normally excludes the open bay and lower, broader major tidal tributary mainstems where water clarity would generally be better.

Figure 4.5-5 Geographic and Statistical Distributions of 273 Probabilistic Sites based on Water Clarity.

Near-Bottom Dissolved Oxygen: Dissolved Oxygen (DO) profiles from near-surface (0.5 m) to near-bottom (0.5 m above sediment) were recorded during all 275 site visits. Near-bottom DO concentrations are summarized here as one element in the NCCA Water Quality Index (WQI) for site characterizations. They are also utilized in the Weight-of-Evidence (WOE) site assessment for Aquatic Life Designated Use (ALU), to be described later in this chapter. Of the 273 bottom DO measures evaluated here, 232 (84.98 ± 1.88%) were classified as "Good" based on NCCA criteria. An additional 38 sites (13.92 ± 4.12%) were classified as "Fair" and only 3 sites (1.10 ± 1.24%) were classified as "Poor."

The geographic and statistical distributions of bottom DO measurements, evaluated by the NCCA criteria, are summarized in the map and table of Figure 4.5-6. There is no indication that any strong regional or local influence depressed bottom dissolved oxygen concentrations within the estuarine area sampled under the Virginia state survey design. Virginia's estuarine waters would earn an overall score of "Good" under the most protective Virginia standard of 4.0 mg/L, under the less protective CBP DO standard of 3.2 mg/L, or under the least protective NCCA criterion (2.0 mg/L), since under all three the proportion of "Poor" sites was less than 10% of the total and considerably more than 50% of the sites were in "Good" condition.

Bottom Dissolved Oxygen Class	Range (NCCA Criteria)	Stations	Percentage
Good	> 5.0 mg/L	232	84.98 ± 4.26%
Fair	2.0 - 5.0 mg/L	38	13.92 ± 4.12%

Water Quality Index (WQI): The five water quality metrics discussed above are integrated into a general Water Quality Index (WQI) for site characteizations. Discussions early in 2013, related to the Fifth NCCA Report ("Progress Update – National Webinar – National Coastal Condition Assessment." U.S. Environmental Protection Agency - 14 January 2013), raised the question of whether or not the water clarity metric should be included in this index, not only because of the difficulty in establishing appropriate local criteria, but also because water clarity is such an ephemeral characteristic of the local water bodies (*i.e.*, varies from hour to hour, minute to minute). For this reason, calculations of the Water Quality Index in the current chapter have been carried out both including and excluding the Water Clarity metric. Table 4.5-3 summarizes the criteria used for both indices.

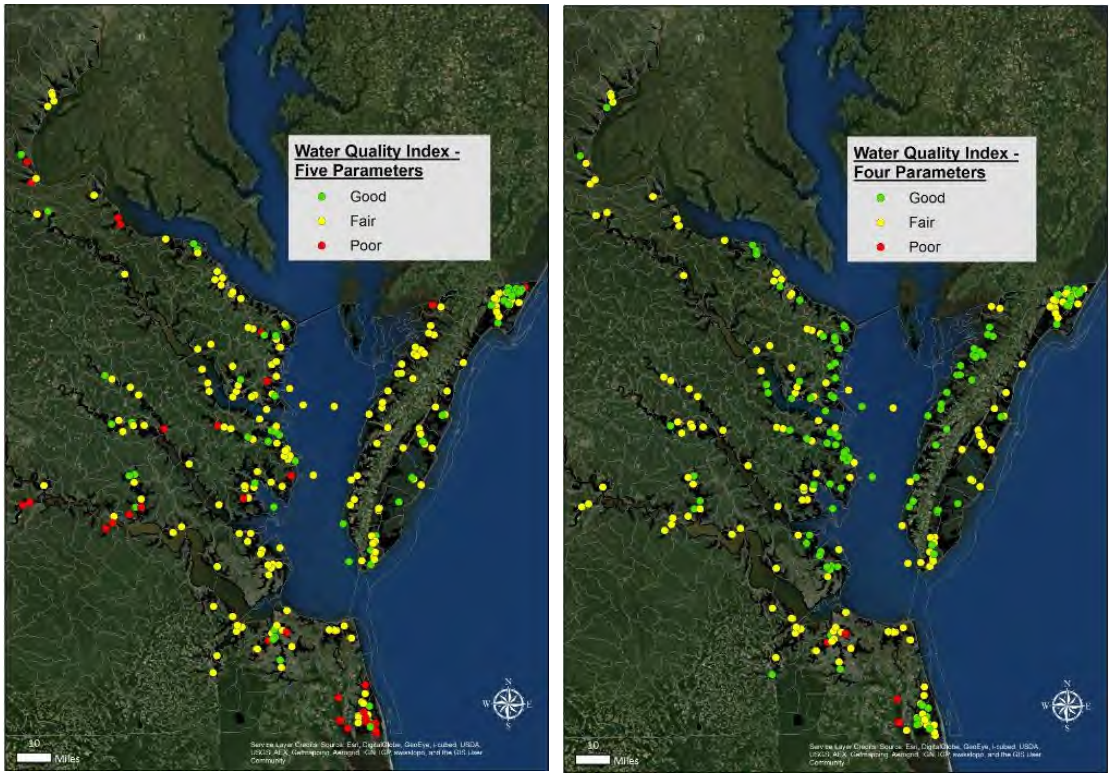

Table 4.5-3 Criteria for Characterizing the Site-specific Integrated Water Quality Index (WQI) based on Five (WQI_5) or Four (WQI_4) Water Quality Parameters. The four parameter WQI used for the Great Lakes in NCCA Report V (USEPA 2015) employed the same thresholds as the five parameter estuarine WQI.

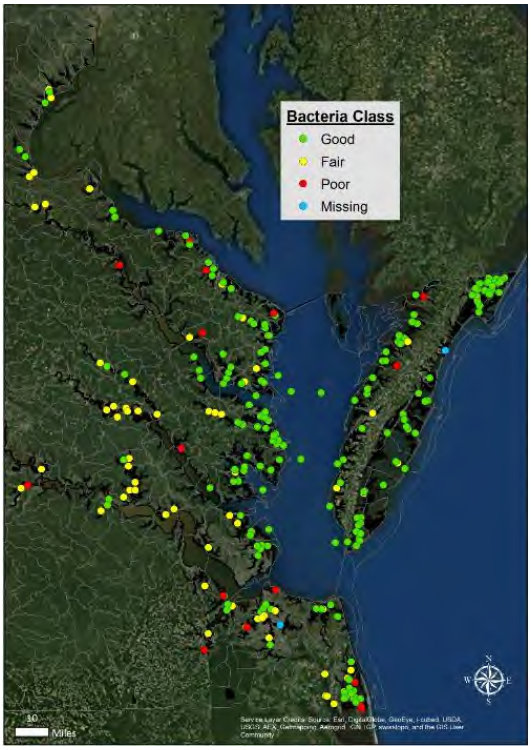
Rating	Thresholds
Good	A maximum of one indictor is rated fair, and no indicators are rated poor
Fair	One of the indicators is rated poor, or two or more are rated fair
Poor	Two or more of the indicators are rated as poor
Missing	Two component indicators are missing, and the available indicators do not suggest a fair or poor rating

The tables in Figure 4.5-7 summarize site-specific WQI characterizations including the integrated, mixed criteria water clarity metric (A – WQI_5) and excluding the water clarity metric (B – WQI_4). It is evident from comparison of the two tables that the the contribution of the water clarity metric has an overwhelming influence on individual site characterizations. Removal of the single water clarity metric increased the number of "Good" characterizations for sites from 57 (20.88 ± 4.84%) to 113 (41.39 ± 5.87%) and decreased the number of "Fair" characterizations from 182 (66.67 ± 5.62%) to 155 (56.78 ± 5.90%). The number of "Poor" characterizations was reduced from 34 (12.45 ± 3.93%) to 5 (1.83 ± 1.60%), but was insufficient to change Virginia's "Fair" regional characterization based on the WQI because the proportion of sites characterized as "Good" was less than 50% under both five-metric and four-metric indices. Refer to Table 4.5-2b for scoring cutpoints of WQI regional characterizations.

Five Parameter Water Quality Index (WQI_5)	Stations	Percentage
Good	57	20.88 ± 4.84%
Fair	182	66.67 ± 5.62%
Poor	34	12.45 ± 3.93%
Missing	0	0.00 ± 0.00%
Total	273	100.00%

Four Parameter Water Quality Index (WQI_4)	Stations	Percentage
Good	113	41.39 ± 5.87%
Fair	155	56.78 ± 5.90%
Poor	5	1.83 ± 1.60%
Missing	0	0.00 ± 0.00%
Total	273	100.00%



A – With Clarity **B – Without Clarity**

Figure 4.5-7 Geographic Distribution and Characterizations of 273 Probabilistic Estuarine Sites based on the Water Quality Index (WQI), A - Calculated with five metrics, including the Integrated, Mixed Criteria Water Clarity Metric and B - with four metrics, excluding the Integrated, Mixed Criteria Water Clarity Metric.

Other Water Quality Measures: In DEQ's state design Estuarine Probabilistic Monitoring Program the agency added on several water column parameters that have not traditionally been required for NCCA surveys. The first of these consisted of near-surface bacterial monitoring and the second (2008 – 2011) consisted of the near-surface sampling and subsequent analysis of trace metals (both dissolved and total). The results from these efforts are discussed in the following sections.

Bacteria: Virginia Code specifies instantaneous maximum Water Quality Standards for primary contact recreational use of freshwater (including tidal fresh) of 235 cfu/dL of *E. coli* and for transitional and saltwater of 104 cfu/dL of enterococci. For scoring individual sites on the basis of bacterial contamination, the salinity at the time of sampling was used to classify the site salinity zone, and then the measured concentration of the appropriate bacterial group was evaluated (*E. coli* in tidal fresh and enterococci in oligohaline, mesohaline, polyhaline and euhaline). If the appropriate bacterial group was below detection limits the site was characterized as "Good". If the appropriate bacterial group was at or in excess of the corresponding instantaneous maximum standard concentration, the site was characterized as "Poor". If the appropriate bacterial concentration was measurable (*i.e.*, above zero) and was below the corresponding standard the site was characterized as "Fair".

The majority of the 273 sites (190 = 69.60 ± 5.48%) were characterized as "Good", and only 16 (5.86 ± 2.80%) were characterized as "Poor" for bacterial contamination. The geographic distribution and characterizations of the sites are illustrated in the map of Figure 4.5-8[4].

Bacteria	Range (cfu/dL) Fresh / Salt	Stations	Percentage
Good	0 / 0	190	69.60 ± 5.48%
Fair	1 - 235 / 1 - 104	65	23.81 ± 5.07%
Poor	> 235 / > 104	16	5.86 ± 2.80%
Missing	N/A	2	0.73 ± 1.02%
	Total	273	100.00%

Figure 4.5-8 Geographic Distributions and Characterizations of 273 Probabilistic Estuarine Sites based on Bacterial Contamination (2009 – 2014).

[4] No statistical summaries are presented for bacteria, because the bacterial counts constitute a discontinuous variable with varying intervals between values. Also, the integrated results are from two different groups of bacteria in different habitats, each with different water quality standards and threshold criteria.

EPA's National Coastal Condition Assessment Reports (U.S. EPA 2001, 2004a, 2008, 2012) do not provide criteria for site characterizations based on bacterial contamination, nor are thresholds available for regional characterizations. Best professional judgment would suggest that because almost 70% of the samples contained no detectable bacteria of interest ("Good"), and bacterial water quality standards were exceeded in less than 10% of the samples ("Poor"), the overall condition of Virginia's estuarine waters based on bacterial contamination was "Good".

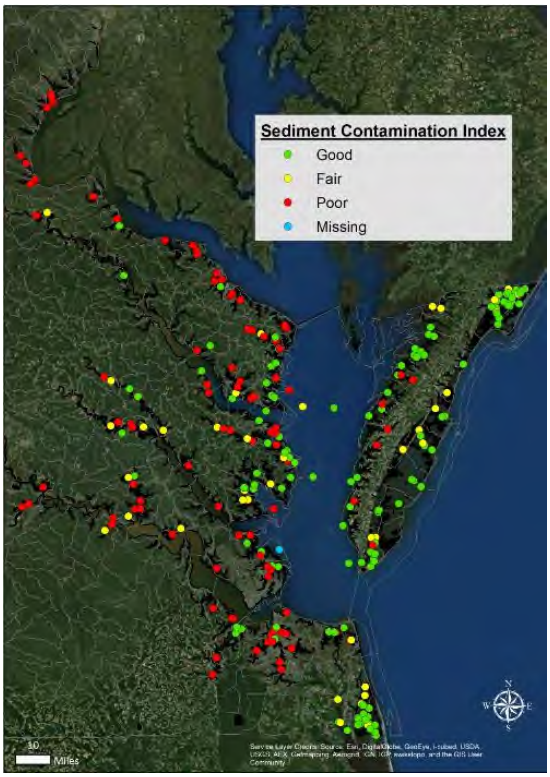
Dissolved Trace Metals in the Water Column: Between 2008 and 2011, DEQ's Estuarine Probabilistic Monitoring (ProbMon) Program collected clean dissolved and total trace metals samples from near surface waters (0.3 m depth) at 182 probabilistic estuarine sites. Results from the entire 2008 – 2011 period were reported in the 2014 IR and no additional clean dissolved metals samples were collected in 2013 or 2014. Please refer to the 2014 Report for a complete discussion of the clean dissolved metals results and the justification for discontinuing this monitoring effort. The clean dissolved metals results are included in the summary table of site attributes and stressor prevalence at the end of this chapter.

Sediment Quality

Integrated Sediment Chemistry Index: Prior to the 2010 survey, the NCCA Program had considered three sediment characteristics important in the evaluation of sediment quality: (1) sediment chemical contamination, (2) sediment toxicity, and (3) sediment total organic carbon (TOC) content. Each of these characteristics had been evaluated separately in earlier NCCA Reports, and the three evaluations were subsequently integrated into a single Sediment Quality Index (SQI). Sediment TOC was removed from the SQI for the 2010 NCCA Survey (USEPA 2015) and the previously applied characterization of sediment chemical contamination was replaced with two new measures, the mean Effects Range Median Quotient (mERM-Q)[5] and the Logistic Regression Model (LRM)[6] (including the concept of utilizing the maximum probability (P_{max}) of acute toxic effects among the sediment contaminant analytes to characterize the ecological condition of a site). EPA used the P_{max} value in conjunction with the mERM-Q to characterize individual sites in relation to their ecological condition. In order to be classified as "Good" a site was required to have a mean ERM Quotient less than 0.1 and a Logistic Regression Model P_{max} < 0.5. The NCCA threshold criteria for characterizing sediment chemical contaminants and toxicity are summarized in Table 4.5-4, and the general criteria are summarized in Table 4.5-5, below. In summary, if both indicators (mERM-Q and P_{max}) are rated "Good" or if the mERM-Q is rated as "Good" and P_{max} is rated "Fair", the site is characterized as "Good" for sediment chemistry.

Table 4.5-4 NCCA 2010 Guidelines for Characterizing Sediment Contamination by Site.

NCCA Site Characterization Guidelines for Estuarine Sediment Contaminantion			
	Good	**Fair**	**Poor**
Sediment Contaminants	**mean ERM-Q < 0.1 and LRM $P_{max} \leq 0.5$**	**mean ERM-Q > 0.1 and < 0.5 or LRM P_{max} > 0.5 but < 0.75**	**mean ERM-Q $\geq$ 0.5 or LRM $P_{max} \geq .75$**
Sediment Toxicity: Test results	**Not significantly less than control (p > 0.05) and control-corrected survivorship ≥ 80%**	**Significantly < control (p < 0.05) and contol-corrected survival ≥ 80% or not significantly less than control (p > 0.0) and control-corrected survival > 80%**	**Significantly less than control (p < 0.05) and control-corrected survival < 80%**



[5] The mean Effects Range Median (ERM) Quotient (mERM-Q) is described by Hyland et al. (1999, 2003).

[6] The Logistic Regression Model was included in the 2010 Technical Report (USEPA 2016) and also described in earlier publications (LRM - Field et al., 1999; Field et al., 2002).

Table 4.5-5 Site Characterization Guidelines for the Integrated Sediment Chemistry Index based on the mERM-Q and LRM P_{max} Indicators.

Sediment Chemical Contamination Class	Site characterization Guidelines for the Integrated (mERM-Q and LRM P_{avg}) Sediment Chemistry Index (SCI)
Good	If both indicators are rated as Good or only P_{avg} is rated as "Fair"
Fair	If both indicators are rated as "Fair" or mERM-Q is "Fair" and P_{avg} is "Good"
Poor	If either indicator is rated as "Poor"
Missing	If both indicators are missing

The geographic distribution and characterization of sites by the Integrated SCI are summarized in Figure 4.5-9.

Sediment Chemical Contamination Class	Stations	Percentage
Good	131	47.99 ± 5.95%
Fair	42	15.38 ± 4.30%
Poor	99	36.26 ± 5.73%
Missing	1	0.37 ± 0.72%
Total	273	100.00%

Figure 4.5-9 Sediment Chemical Contamination Index (SCI) Integrating the Results from the mERM-Q and the LRM P_{max} Characterizations. No color-coded percentile distribution is possible because the index is derived from the characterization classes ("Good", "Fair", "Poor") of the two individual chemical contamination indices (mERM-Q and LRM P_{max}).

Equilibrium Partitioning Sediment Benchmark (ESB) for PAH Mixtures: The U.S. EPA has published several procedures for the derivation of contaminant equilibrium partitioning sediment benchmarks (ESBs) for the protection of benthic organisms. Such benchmarks consider the potential cumulative (additive and/or synergistic) effects of multiple related contaminants (e.g., various metals or various PAHs, etc.) within the same sediment sample. DEQ uses the ESB for PAH mixtures as an additional line of

information in its weight-of-evidence assessments for aquatic life use, but it is not included in the Integrated Sediment Chemistry Index discussed above.[7]

This study includes 23 of the 34 PAH analytes. EPA's publication cited above provides correction factors to estimate the reliability of predicting a contaminant equilibrium partitioning sediment benchmark score for the total suite (34 analytes, ESP34) based on the results from these 23 analytes (ESB23). Multiplying the total score derived from summing the 23 analytes by a correction factor of 1.64 provides an estimate of the expected median score for the ESP34 among the N = 2001 reference samples initially used to derive the original ESB relationship. A Microsoft Excel ® spreadsheet that carries out these calculations automatically for individual site assessments based on the Sediment Quality Triad is provided in DEQ's Weight-of-Evidence workbooks. The Weight-of-Evidence assessment procedure and the associated Excel workbooks are described in DEQ's 2014 Assessment Guidance Manual (DEQ-WMA 2014).

When the ESB_{23} to ESB_{34} correction factor was applied to the results from the 272 estuarine sediment samples in this study, estimated ESB_{34} scores varied from 0.000 to 4.474. Two hundred sixty-eight (98.17 ± 1.60%) of the samples had expected ESB_{34} scores < 1.000, indicating that undesirable effects from dissolved PAHs would not be expected to impact the benthos. Sites with estimated ESB_{34} scores < 1.000 were consequently characterized as being of "Low" risk to benthic communities ("Good"). Sites with estimated ESB_{34} scores greater than 1.000 and less than or equal to 2.000 (N = 3; 1.10 ± 1.24%) were characterized as being of "Medium" risk to benthic communities ("Fair"), because a marginal rather than a severe impact would be expected. Estimated ESB_{34} scores greater than 2.000 and less than or equal to 5.000 (N = 1; 0.37 ± 0.72%) were characterized as being of "High" risk to benthic communities ("Poor"), and no sites had ESB_{34} scores exceeding 5.000, which would be characterized as being of "Very High" risk to benthic communities ("Very Poor"). The ranges of estimated ESB_{34} (adjusted ESB_{23}) scores, the resultant characterizations, and the numeric distribution of the results are summarized in Figure 4.5-12, below. The single "Poor" site was in the Elizabeth River, Southern Branch (ESB_{34} = 4.47). The three "Fair" sites were in Stoakes Creek (south of Gwynn Island – ESB_{34} = 1.78), White House Cove (Poquoson - ESB_{34} = 1.63) and the lower Appomattox River (just above Hopewell – ESB_{34} = 1.00).

As previously indicated, the ESB_{34} provides an estimated benthic risk factor from dissolved PAHs in the interstitial water. It is useful in inferring a possible cause and pathway for benthic impairment at a site, but a high ESB_{34} score does not necessarily mean that PAHs are an unimportant contaminant. PAHs bound to TOC in organic detritus may be ingested by benthic organisms and consequently result in degradation much more severe than would be indicated by the ESB_{34} itself.

The Role and Distribution of Individual Analytes in Sediment Contamination: Individual metals contribute to both the mean ERM Quotient and to the P_{max} statistic of the Logistic Regression Model. Individual PAHs contribute sporadically, although total PAHs seldom approach the Effects Range Median value for this composite group of analytes. Only three metals were observed to exceed their ERM values among the 272 sediment chemistry samples evaluated for this report: Zinc (Zn - 4 exceedances), Cadmium (Cd - 2 exceedances), and Nickel (Ni - 1 exceedance). Various individual PAHs induced high probabilities of toxic effects on benthos, but total PAHs never approached their Effects Range Median threshold, which is relatively high (ERM = 44,792 µg/Kg). Total PAHs did, however exceed their ERL value (ERL = 4,022 µg/Kg) on six occasions. For the purpose of this report, total PAHs are the simple sum of all 23 PAHs analyzed in each sample Both ERL and ERM exceedances by selected metals and total PAHs are summarized in Table 4.5-6.

[7] The procedure for calculating the ESB for PAH mixtures was described in detail in DEQ's 2014 Integrated Report (DEQ WQA, 2014). Unfortunately, following release of the 2014 IR, an error was discovered in the formula calculating the fraction of Total Organic Carbon (TOC) in the sediment and the fraction of TOC, which chemically sequesters PAHs from the water, was greatly underestimated. Consequently the calculated risk factor to benthos from dissolved PAHs in the interstitial water within the sediment was greatly overestimated in the 2014 IR. This error has now been corrected and the results presented in the current IR are more representative than those reported in 2014.

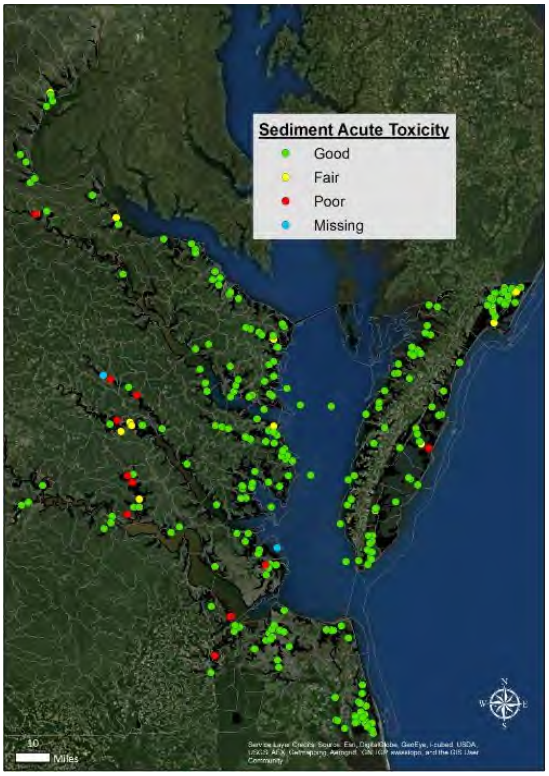


Table 4.5-6 Number of Effects Range Low (ERL) and Effects Range Median (ERM) Exceedances Observed for Selected Metals and Total PAHs.

	Number of Exceedances among 272 samples	
Analyte	**ERL**	**ERM**
Arsenic (As)	85	0
Cadmium (Cd)	46	2
Chromium (Cr)	2	0
Copper (Cu)	41	0
Lead (Pb)	17	0
Mercury (Hg)	19	0
Nickel (Ni)	77	1
Zinc (Zn)	36	4
Total PAHs	6	0

An addendum to this IR chapter, which includes maps of the geographic distributions and summaries of the statistical distributions of selected metals and total PAHs, is available from DEQ upon request. Contact donald.smith@deq.virginia.gov or (804) 698-4429 to request an electronic copy via email.

Sediment Toxicity: Sediment toxicity (SedTox) has been included as one element of sediment quality since the inception of the Coastal 2000 Initiative. In National Coastal Condition Reports I – IV (USEPA, 2001, 2004, 2008, 2012) EPA classified the results of SedTox tests as either "Good" (C-CS ≥ 80%) or "Poor" (C-CS < 80%), with no intermediate class of "Fair" defined. Mortality greater than 20% (C-CS < 80%) was considered to be biologically or ecologically meaningful, without comparisons with controls to evaluate the statistical significance of differences. Beginning with NCCA Report V (USEPA 2015), and in DEQ's 2014 IR and the current Report, an additional intermediate class of "Fair" has been defined for those sites with transitional results where C-CS ≥ 80% but a one tailed statistical test revealed a significantly ($p \leq 0.05$) lower survivorship than controls, or where C-CS was < 80% but statistically significance difference from controls could not be verified ($p > 0.05$).

The characterizations and geographic distributions of the sites using these criteria are summarized in Figure 4.5-10, below. Applying the current criteria, 244 results from 273 sites (89.38 ± 3.67%) were characterized as "Good" for sediment toxicity, 15 sites (5.49 ± 2.72%) were characterized as "Fair", and 12 results (4.40 ± 2.44%) were characterized as "Poor." Two sites were characterized as "Missing" for sediment toxicity results (0.72 ± 1.02% - completeness = 99.28%). No sample was collected at one site because of densely compacted sand substrate, and the results from the second site, 8-MPN028.78 in tidal freshwaters of the Mattaponi River, were discarded because of an excessive bloom of iron-fixing bacteria that killed most of the test organisms. The toxicity of chemical contaminants could not be verified.

Sediment Acute Toxicity Class	Stations	Percentage
Good	244	89.38 ± 3.67%
Fair	15	5.49 ± 2.72%
Poor	12	4.40 ± 2.44%
Missing	2	0.73 ± 1.02%
Total	273	100.00%

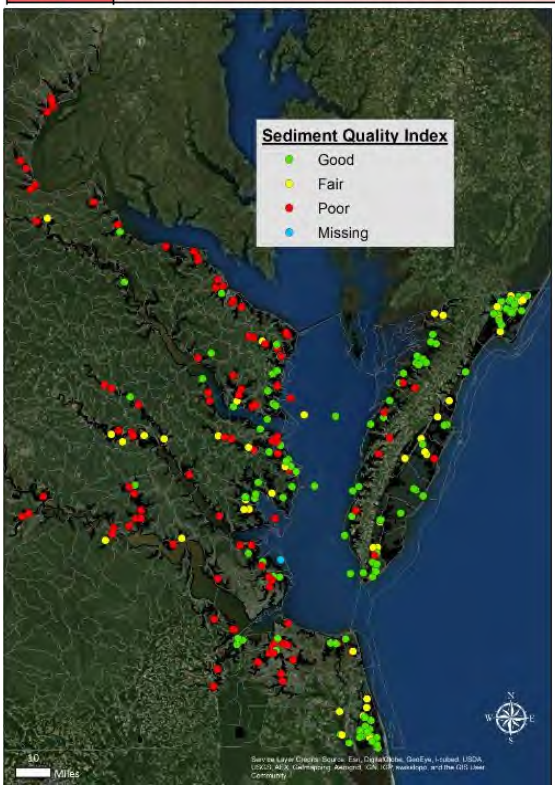
Figure 4.5-10 Geographic Distribution and Characterization of 273 Estuarine Probabilistic Sites Based upon Acute Sediment Toxicity (2009 – 2014).

Following the current criteria, Virginia's estuarine waters as a whole would have less than 5% of the sites in "Poor" condition (4.40 ± 2.44%) and almost 90% (89.38 ± 3.67%) in "Good" condition. This would support the choice of a "Good" characterization for the estuarine area as a whole based on sediment toxicity.

It is interesting to note that, as is often the case, we have not observed significant acute mortality in sediment from many of the sites where we have measured significant chemical contamination. This is especially notable in the Elizabeth River system, where sediment contamination by many metals (Zn, Ni, Cu, Cd, and As) and organic compounds (primarily by PAHs and PCBs) is widespread. This may be an indication that the chemical contaminants are in a form not readily available to the benthic community (or toxicity test organism), or that the available concentrations are so low that only chronic effects would be evident. In contrast, significant toxicity is often observed during tests of sediment in which chemical analyses have not revealed a probable cause of the toxicity observed. In the environment, complex mixtures of contaminants of various classes (trace metals, pesticides, PAHs, etc.) even at relatively low concentrations, as well as other unmeasured factors, often have unpredictable and at times severe effects.

Sediment Quality Index (SQI): Once both sediment quality indicators (sediment chemistry and sediment toxicity) were scored for a site, NCCA Report V (USEPA, 2015) calculated an integrated Sediment Quality Index (SQI) to characterize overall sediment quality at the site. Guidelines for determining the SQI are described in Table 4.5-7, below. In the SQI determinations that follow, the Integrated Sediment Chemistry Index (SCI) and Sediment Toxicity were used to characterize sediment contamination. The resultant characterizations and their geographic distribution are summarized in Figure 4.5-11, below.

Based on the NCCA guidelines in Table 4.5-8, below, Virginia's region-wide estuarine sediments would be characterized as "Poor" because the percentage of sites with "Poor" sediment was more than 15%.



Ecologically, the most representative index of sediment "quality" is the condition of the benthic community that resides in it. Benthic community status is discussed below, and will later be integrated into an overall site score for a characterization of statewide estuarine condition.

Table 4.5-7 Scoring Guidelines for Characterizing Individual Sites using the Sediment Quality Index (SQI). *(Taken from USEPA, 2015) The two indices used in this case were the Integrated Sediment Chemistry Index (SCI) and sediment Toxicity.*

Sediment Quality Index Guidelines		
Good	**Fair**	**Poor**
Both indicators are rated good.	At least one indicator is rated fair and none are rated poor.	At least one indicator is rated poor.

Table 4.5-8 Scoring Guidelines for Characterizing Regions based on the Sediment Quality Index (SQI). (Taken from U.S. EPA, 2012)

Rating	Cutpoints
Good	Less than 5% of the coastal area is in poor condition, and more than 50% of the coastal area is in good condition.
Fair	5% to 15% of the coastal area is in poor condition, or 50% or less of the coastal area is in good condition.
Poor	More than 15% of the coastal area is in poor condition.

Sediment Quality Index	Stations	Percentage
Good	123	45.05 ± 5.93%
Fair	45	16.48 ± 4.42%
Poor	104	38.10 ± 5.79%
Missing	1	0.37 ± 0.72%
Total	273	100.00%

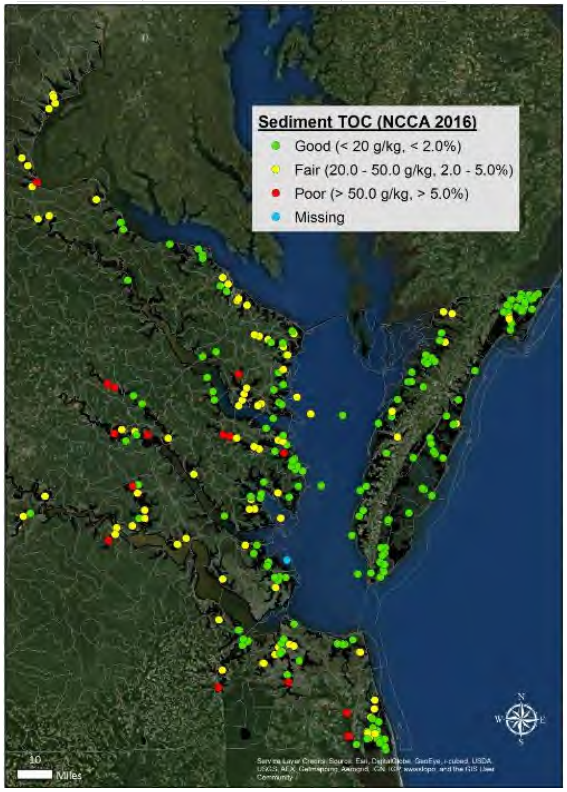


Figure 4.5-11 The Geographic Distribution and Characterizations of 273 Probabilistic Estuarine Sites based on the Sediment Quality Index – SQI (2009 – 2014). The Sediment Quality Index is derived from site characterizations by the Sediment Chemical Contamination Index and Sediment Toxicity.

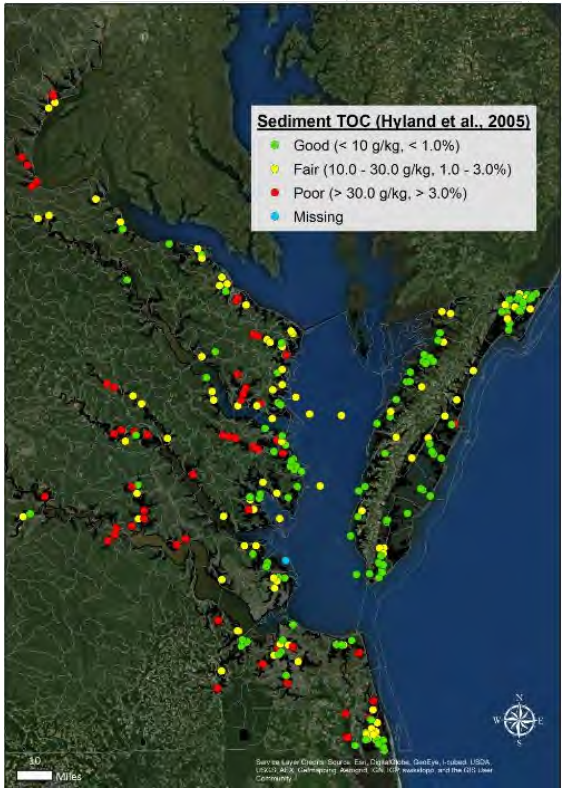
Sediment Total Organic Carbon (TOC): The NCCA Program has traditionally included total organic carbon (TOC) as one element of its Sediment Quality Index (SQI) for an integrated characterization of sediment. TOC, as both a component of and a degradation product from vegetal and animal detritus, is a natural constituent of freshwater and estuarine bottom deposits. TOC in the sediment may chemically bind both organic and inorganic pollutants and reduce their availability in dissolved form to benthic organisms. Changes in temperature and water chemistry (e.g., pH and dissolved oxygen), however, may result in the release of previously bound contaminants. TOC also provides food for many benthic organisms, in which case bound toxic contaminants would also be ingested. Excessive concentrations of TOC in local sediment deposits, regardless of degree of contamination, may alter the composition of benthic communities, and promote the dominance of pollution-tolerant species. High concentrations of TOC may also indicate local foci of sediment deposition where available pollutants may accumulate. Because of the difficulty in interpreting these potentially contradictory effects of TOC in the sediment, it was removed as a component indicator of the SQI for the fifth NCCA Report. It is still utilized in conjunction with percent fine particles (silt/clay) in the sediment to interpret other sediment quality results.

The TOC ranges utilized for characterizations here come from two sources: (1) NCCA Report IV (U.S. EPA, 2012) and (2) Hyland et al, 2005. Under the NCCA classification, 171 sites (62.64 ± 5.76%) were characterized as “Good” (TOC < 2.0%), 85 sites (31.14 ± 5.52%) were characterized as “Fair” (TOC 2.0% – 5.0%), and only 16 sites (5.86 ± 2.80%) were characterized as “Poor” (TOC > 5.0%) for sediment TOC composition. A single site lacked a sediment TOC sample because the substrate was too compacted to sample successfully. Following the guidelines provided in NCCA Report IV, Virginia’s estuarine waters would earn a “Good” overall rating based on sediment TOC, because the percentage of estuarine sites with a “Poor” characterization is well below 10% and “Good” characterizations exceeded 50%. Characterizations following the criteria of Hyland et al. (2005) resulted in 121 “Good” sites (44.32 ± 5.92%), 92 “Fair” sites (33.70 ± 5.63%), and 59 “Poor” sites (21.61 ± 4.90%). An overall rating based on these results would characterize Virginia’s estuarine waters as “Poor” because more than 20% of the sites were in this category.



The geographical and statistical distributions of sites based on their sediment TOC characterizations are summarized in Figure 4.5-12. The sites with the highest sediment TOC concentrations were found in low gradient, coastal plain streams such as the North Landing River (17.7% TOC), the Chickahominy River (12.9% TOC), Upper Chippokes Creek (9.5% TOC), and the Piankatank River (8.8% TOC), while those with the lowest TOC concentrations (< 0.02% TOC) were generally from channels and inlets of coastal Delmarva.

Sediment TOC (NCCA 2010)	Range	Stations	Percentage
Good	< 20 g/Kg (< 2.0%)	171	62.64 ± 5.76%
Fair	20.0 - 50.0 g/Kg (2.0 - 5.0%)	85	31.14 ± 5.52%
Poor	> 50.0 g/Kg (> 5.0%)	16	5.86 ± 2.80%
Missing	N/A	1	0.37 ± 0.72%

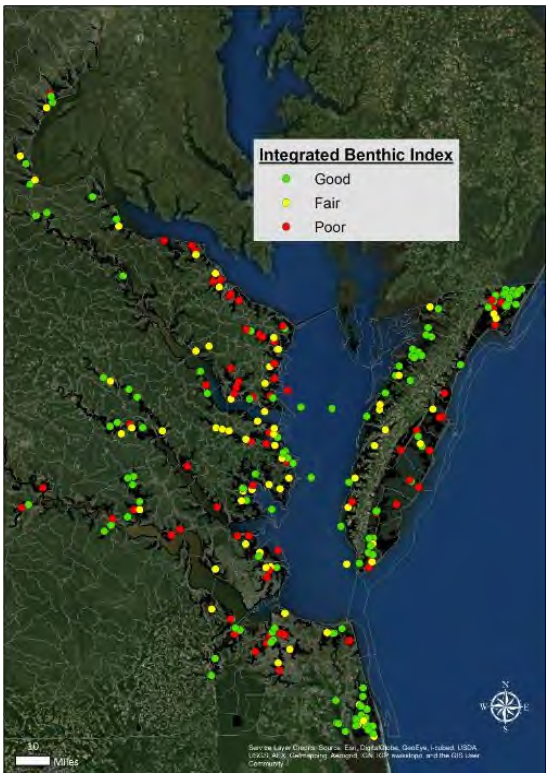
Benthic Community

Benthic Quality Index: A benthic index, also commonly referred to as a Benthic Index of Biological Integrity or B-IBI, is a scientific tool used to identify, classify, and interpret the structure and function of benthic communities, often in relation to environmental stressors such as water pollution. Such indices are generally derived from the results of local or regional benthic surveys, and are consequently geographically restricted in their application. There are three commonly applied regional benthic indices that are appropriate for use in Virginia's estuarine waters, the Chesapeake Bay Program B-IBI (CBP B-IBI - Weisberg et al., 1997), the Mid-Atlantic B-IBI (MAIA B-IBI - Llansó et al., 2002a, 2002b) and the EMAP Index of Estuarine Condition for the Virginian Biogeographic Province (EMAP VP-IEC – Paul et al., 2001).



The CBP B-IBI was developed specifically for estuarine waters of the Chesapeake Bay watershed and it is the most appropriate for use in those waters. The MAIA B-IBI was developed for waters of the Mid-Atlantic Region, which includes the estuarine waters of the Delaware Bay and Chesapeake Bay watersheds, the coastal bays of the Delmarva Peninsula, and the Albemarle-Pamlico estuarine system of southeastern Virginia and northeastern North Carolina. It is the only one of the three indices that is appropriate in all of Virginia's estuarine waters. The EMAP VP-IEC was developed for the Virginian Biogeographic Province, which extends from Cape Cod to the mouth of Chesapeake Bay, but excludes the southeastern Virginia coastal area. All three indices were calculated for the benthic data from each site in this study, but most weight was given to the interpretation of CBP B-IBI within the Chesapeake watershed, and to the interpretation of the MAIA B-IBI in coastal waters of Delmarva and the Back Bay/North Landing River portion of the Pamlico Sound system.

The structures, similarities and dissimilarities, scoring and site characterizations using all three benthic indices were discussed in detail in DEQ's 2014 IR. All three benthic indices were calculated for benthic samples from each of the sites characterized herein. During testing and calibrating the Pavg statistic of the Linear Regression Model, described earlier in this report, it was noted that the EMAP-IEC was as capable of discriminating between lightly and severely contaminated sediments as were either of the multimetric B-IBIs mentioned above (Smith, 2016). Consequently, all three indices were integrated into a single average benthic class. Each site was first scored as "Good", "Fair", or "Poor" by each of the benthic indices. The results for each index are summarized in Table 4.5-9. If all three indices agreed in their characterizations, the common characterization was assigned to the integrated index: all three "Good" – 100 sites = 36.63% ± 5.74%, all three poor – 52 sites = 19.05% ± 4.68%. No sites were characterized as "Fair" by all three indices. The sites where all three indices did not agree were evaluated using best professional judgement. Within the Chesapeake Bay watershed the CBP B-IBI was given higher weight, elsewhere the MAIA B-IBI was given higher weight, but the overall evaluation of the site considered all three indices. If the MAIA and EMAP indices agreed in giving a Chesapeake Bay site a "Poor" rating while the CBP index indicated "Good", a "Fair" characterization was assigned. Likewise, if the CBP and EMAP indices agreed in contradicting the MAIA rating for a coastal Delmarva site, an intermediate characterization was assigned.

Table 4.5-9 Site Characterizations of 273 Probabilistic Estuarine Sites (2009 – 2014) by the Three Independent Benthic Indices utilized in the Present Report: The Chesapeake Bay Program (CBP) B-IBI, The Mid-Atlantic (MAIA) B-IBI, and the national Environmental Monitoring and Assessment Program (EMAP) Index of Estuarine Condition for the Virginian Biogeographic Province (VP-IEC).

► Benthic Index ►	CBP B-IBI		MAI B-IBI		EMAP IEC	
▼ Class ▼	Count	Percentage	Count	Percentage	Count	Percentage
Good	127	46.52 ± 5.94%	196	71.79 ± 5.36%	159	58.24 ± 5.88%
Fair	28	10.26 ± 3.61%	2	0.73 ± 1.02%	14	5.13 ± 2.63%
Poor	118	43.22 ± 5.90%	75	27.47 ± 5.32%	100	36.63 ± 5.74%
Missing	0	0.00%	0	0.00%	0	0.00%
Total	273	100.00%	273	100.00%	273	100.00%

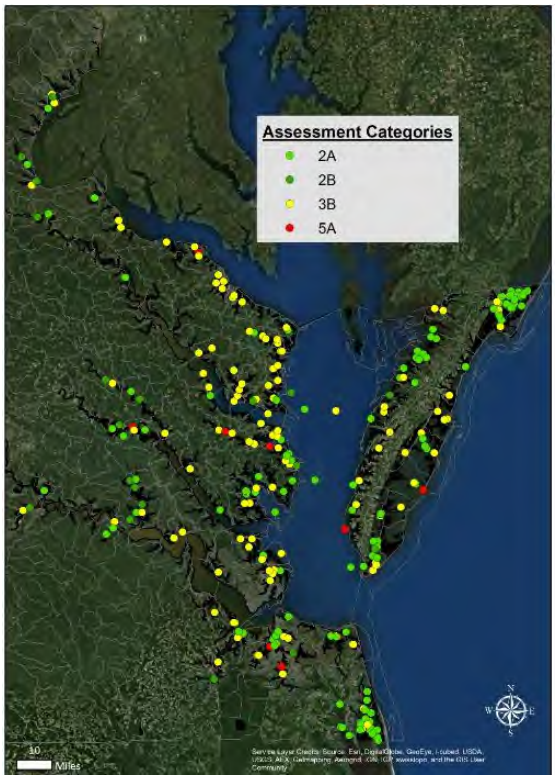
The final geographic and statistical distributions for integrated benthic characterizations are summarized in Figure 4.5-13. Following the NCCA guidelines in Table 4.5-2b, Virginia's estuarine waters would be given an overall rating of "Poor" for benthos, since more than 20% of the individual sites were characterized as "Poor", even though nearly 50% of the sites were characterized as "Good".

Integrated Benthic Class	Stations	Percentage
Good	128	46.89 ± 5.95%
Fair	71	26.01 ± 5.23%
Poor	74	27.11 ± 5.30%
Missing	0	0.00%
Total	273	100.00%

Figure 4.5-13 Geographic Distribution and Characterizations of 273 Probabilistic Estuarine Sites based on the Integrated Benthic Index (2009 – 2014).

Weight-of-Evidence (WOE) Assessment

Weight-of-Evidence assessments of each individual site for Aquatic Life Use (ALU) were carried out based primarily upon the Sediment Quality Triad (SQT) of sediment chemistry, sediment toxicity, and benthic community wellbeing. All three of these measures are considered to be temporally integrative, providing an assessment of environmental conditions experienced by the benthic community during the period prior to the time of sampling. The other water quality parameters (*e.g.*, nutrients, bacteria, dissolved metals, DO, temperature, pH, *etc*.) that are measured at probabilistic sites are considered to be isolated instantaneous observations and are insufficient for assessment purposes because the intensity and duration of such stressors are unknown. The evaluation and interpretation of the SQT is carried out with the use of an analytical matrix (Chapman et al., 1986, 1987) that is described in DEQ's Water Quality Assessment Guidance Manual for the 2016 305(b)/303(d) Integrated Water Quality Report (DEQ-WQA, 2016).



The criteria used in this WOE assessment and the Microsoft Excel® workbooks used for the process are also described in the Water Quality Assessment Guidance Manual (*Ibid*.). The site characterizations that are integrated into the WOE assessments have been discussed individually earlier in this report. They include counts of ERM and ERL exceedances (criteria from previous NCCA Reports), the Mean ERM Quotient, the Logistic Regression Model, the Equilibrium Partitioning Sediment Benchmark for PAH

mixtures (ESB_{PAHs} or ESB_{34}), the results of sediment toxicity tests, and taxonomic richness, diversity, and evenness along with the evaluation of benthic community health and function using benthic indices (B-IBIs).

If elevated chemical contamination and/or sediment acute toxicity is observed in conjunction with a degraded or severely degraded benthic community, an assessment of "5A – Impaired" (by toxics) is assigned. If a degraded or severely degraded benthic community is observed without chemical or toxicological corroboration, an assessment of "3B - observed effects with insufficient information" is assigned, even though ancillary information may suggest a possible cause other than toxics. A "3B" assessment is also assigned if sediment contamination exceeds sediment quality guidelines specified in the Guidance Manual, but benthic scores are still acceptable. Statistically and ecologically significant sediment toxicity, without chemical corroboration or benthic degradation, is assigned assessment category "2B - waters are of concern to the state but no Water Quality Standard exists for a specific pollutant, or the water exceeds a state screening value. If no benthic degradation, sediment chemical contamination, or sediment toxicity are observed, an assessment category of "2A" is assigned "- waters are attaining all of the uses for which they are monitored (based on the data in the WOE workbook) and there is insufficient data to document the attainment of all [other] uses." Assessments of "2A" or "2B" are characterized as "Good", assessments of "3B" are characterized as "Fair", and assessments of "5A" are characterized as "Poor." Because the assessment category of "5A – Impaired" for ALU is only assigned in cases where benthic degradation is corroborated by sediment chemical contamination and/or sediment acute toxicity, the proportion of sites in this category is less than that observed for many other individual parameters or indices.

Weight-of-Evidence assessments categorized 142 sites (52.01 ± 5.95%) as "Good" (2A or 2B), 122 sites (44.69 ± 5.92%) as "Fair" (3B), and 9 sites (3.30 ± 2.13%) were assessed as "Poor" (5A – Impaired for ALU by toxics). It must be kept in mind that the low number of 5A – Impaired sites (3.30 ± 2.13%) in comparison with the number of degraded or severely degraded benthic community sites (44.7 ± 5.9%) results from the fact that the WOE assessment is specifically directed at toxics. If benthic degradation by toxics was not substantiated within the sediment quality triad, the WOE assessment was a Category 3B – "Observed effects", with insufficient data to assign a cause, and the site was prioritized for follow-up monitoring. The NCCA Reports provide no thresholds for evaluating weight-of-evidence assessments with the sediment quality triad. The fact that the results contained fewer than 20% "Poor" characterizations and the percentage of "Good" characterizations did not significantly exceed 50% (95% Confidence Interval extends downward to 46.06%) Virginia's estuaries should probably be characterized as "Fair" on the whole for toxics-induced ALU impairment (based on regional thresholds defined in Table 4.5-2b),

The geographic distribution of these results is illustrated in the map of Figure 4.5-14.

Assessment Class	Stations	Percentage	
2A	120	43.96 ± 5.91%	52.01 ± 5.95%
2B	22	8.06 ± 3.24%	
3B	122	44.69 ± 5.92%	
5A	9	3.30 ± 2.13%	
Total	273	100.00%	

Figure 4.5-14 Weight-of-Evidence Assessment Results from 273 Probabilistic Estuarine Sites Sampled between 1 January 2009 and 31 December 2014.

Conclusion

DEQ's estuarine probabilistic monitoring program sampled 273 estuarine sites during the 2009-2014 assessment period. The vast majority of the sites fell within the minor tidal tributaries and embayments of the Chesapeake Bay watershed or in the estuarine waters of coastal Delmarva and the Back Bay / North Landing River region of southeastern Virginia. These sites are categorized using thresholds developed by EPA's National Coastal Condition Assessment Program. On the basis of the four water quality parameters sampled at each site, 41% sites were rated as "good", 57% were rated as "fair", and 2% were rated as "poor". On the basis of sediment chemistry and acute toxicity, 45% of sites were rated as "good", 17% were rated as "fair", and 38% were rated as "poor". Sediment contamination was identified as the second most prevalent stressor. Most of the sites (73%) had benthic communities that were classified as "good" or "fair" according to the Integrated Benthic Index. Hopefully, as the National Coastal Condition Assessment Program continues to refine its thresholds to reflect improvements in scientific understanding, DEQ will be able to improve its ability to detect, identify the source(s) of, and remediate problems in the Commonwealth's estuarine waters.

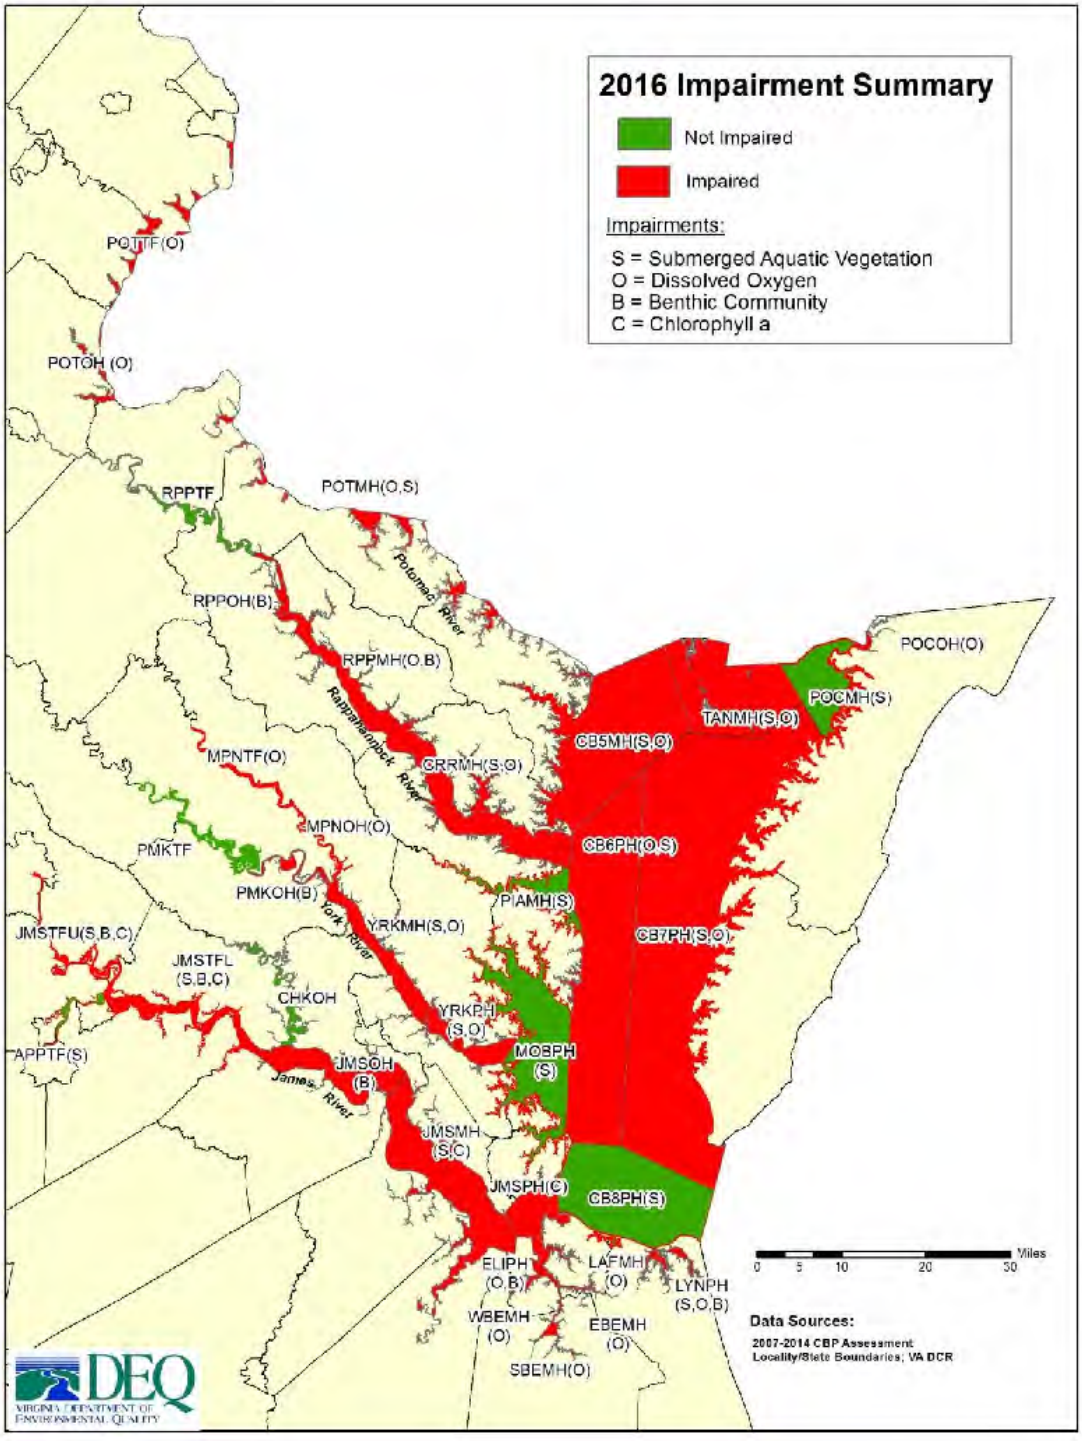
CHAPTER 4.6 CHESAPEAKE BAY ASSESSMENT

(Note: The Federal-Interstate Chesapeake Bay Program, which is responsible for developing water quality standards and assessment protocols for Bay waters, is described in more detail in Chapter 7.7.)

Assessment of Aquatic Life Use in Chesapeake Bay and Its Tidal Tributaries

Summary



The 2016 assessment reveals promising findings for aquatic life use attainment in Virginia's Chesapeake Bay waters. While hypoxia continues to be problematic in both shallow and deeper areas, particularly during the summer months, the number of tributary segments failing assessed dissolved oxygen (DO) criteria during summer months was lower relative to the number reported in the 2014 assessment. For the first time since the adoption of the Bay DO standards, no evidence of chronic hypoxia was found in the James River and Rappahannock River segments for the Open Water sub-use, and the Deep Channel sub-use is met in mainstem segment CB5MH. Chlorophyll standards were fully attained in the oligohaline portion of the James for the first time, though they were not met in the rest of the estuary. Additionally, approximately 47% of the total state-wide submerged aquatic vegetation (SAV) acres goal was attained, up from 46% reported in the 2014 assessment. It is anticipated that progress in Bay aquatic life use attainment will continue to as the Bay Total Maximum Daily Load (TMDL) and Virginia's Watershed Implementation Plan are implemented.

Figure 4.6-1 summarizes the current aquatic life use status for the Bay-specific criteria detailed in 9AVAC25-260-185 (note it does not reflect other impairments such as pH, fish tissue contaminants, or other aquatic life criteria).

The tidal fresh segments of the Mattaponi (MPNTF) and Pamunkey (PMKTF) meet all assessed Bay criteria. However, these areas remain classified as impaired in the Assessment Database (ADB) because short-term criteria established for dissolved oxygen (7-day mean, 1-day mean, and instantaneous minimum) have not been assessed. There are some data available to assess these criteria, but the Chesapeake Bay Program has not yet developed the appropriate assessment protocols. Segments which were over-listed by the EPA in 1999 for dissolved oxygen and currently meet all assessed criteria are assumed to be impaired until all dissolved oxygen criteria for all appropriate designated uses are assessed and determined to be meeting.

The following sections describe in further detail 1) aquatic life sub-uses and criteria, 2) 2016 aquatic life use assessment results and 3) future assessment refinements.

Figure 4.6-1 Impairment status of the Bay aquatic life use.

Chesapeake Bay and Tidal Tributaries Aquatic Life Uses and Criteria

The Chesapeake Bay aquatic life sub-uses described below reflect the different aquatic living resource communities living in the different areas of the Bay. Impairment of any of these sub-categories of aquatic life use is also considered an impairment of the overall aquatic life use. The overall aquatic life use also exists as a distinct designated use (i.e. distinct from the sub-uses) and is assessed with other protocols including benthic Indices of Biological Integrity (IBI), ammonia criteria, and toxicity bioassays.

Designated Uses

Migratory Fish Spawning and Nursery (MSN) Designated Use

This use exists in waters in the Chesapeake Bay and its tidal tributaries that protect the survival, growth and propagation of the early life stages of a balanced, indigenous population of anadromous, semi-anadromous, catadromous and tidal-fresh resident fish species inhabiting spawning and nursery grounds. Figure 4.6-2 illustrates this designated use and detailed geographic descriptions are in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability 2004 Addendum Chesapeake Bay Program Office, Annapolis, Maryland*. The designated use extends from the beginning of tidal waters to the downriver end of spawning and nursery habitats, as determined through a composite of all targeted anadromous and semi-anadromous fish species' spawning and nursery habitats. The designated use extends horizontally from the shoreline of the body of water to the adjacent shoreline, and extends down through the water column to the bottom water-sediment interface. This use applies February 1 through May 31 and exists concurrently with the open-water use.

Shallow-Water Submerged Aquatic Vegetation (SWSAV) Designated Use

This use exists in waters in the Chesapeake Bay and its tidal tributaries that support the survival, growth and propagation of submerged aquatic vegetation (rooted, underwater bay grasses). Figure 4.6-2 illustrates this designated use and detailed geographic descriptions are in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability 2004 Addendum Chesapeake Bay Program Office, Annapolis, Maryland*. This use applies April 1 through October 31 in tidal-fresh, oligohaline and mesohaline Chesapeake Bay Program segments, and March 1 through November 30 in polyhaline Chesapeake Bay Program segments and exists concurrently with the open-water use.

Open-Water (OW) Aquatic Life Designated Use

This use exists in waters in the Chesapeake Bay and its tidal tributaries that protect the survival, growth and propagation of a balanced, indigenous population of aquatic life inhabiting open water habitats. Figure 4.6-2 illustrates this designated use and detailed geographic descriptions are in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability 2004 Addendum Chesapeake Bay Program Office, Annapolis, Maryland*. This designated use applies year-round but the vertical boundaries change seasonally. October 1 - May 31: the open-water aquatic life use extends horizontally from the shoreline at mean low water, to the adjacent shoreline, and extending through the water column to the bottom water-sediment interface. June 1 - September 30: if a pycnocline (i.e. a physical inhibition of mixing due to a rapid change of density in the water column with depth) is present, the open-water sub-use extends down into the water column only as far as the upper boundary of the pycnocline; otherwise, it extends to the water-sediment interface. This designated use is concurrent with the migratory fish spawning and nursery and Shallow-Water submerged aquatic vegetation uses in areas where these uses apply.

Deep-Water (DW) Aquatic Life Designated Use

This use exists in waters in the Chesapeake Bay and its tidal tributaries that protect the survival and growth of a balanced, indigenous population of aquatic life inhabiting deep-water habitats. Figure 4.6-2 illustrates this designated use and detailed geographic descriptions are in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability 2004 Addendum Chesapeake Bay Program Office, Annapolis, Maryland.* This designated use applies to the tidally influenced waters located between the upper and lower boundaries of the pycnocline where, in combination with bottom bathymetry and water circulation patterns, a pycnocline is present and presents a barrier to oxygen replenishment of deeper waters. In some areas, the deep-water sub-use extends from the upper boundary of the pycnocline down to the bottom water-sediment interface. This use applies June 1 through September 30.

Deep-Channel (DC) Seasonal Refuge Designated Use

This use exists in waters in the Chesapeake Bay and its tidal tributaries that protect the survival of a balanced, indigenous population of benthic infauna and epifauna inhabiting deep-channel habitats. Figure 4.6-2 illustrates this designated use and detailed geographic descriptions are in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability 2004 Addendum Chesapeake Bay Program Office, Annapolis, Maryland.* This designated use applies to the tidally influenced waters at depths greater than the lower boundary of the pycnocline in areas where, in combination with bottom bathymetry and water circulation patterns, the pycnocline presents a barrier to oxygen replenishment of deeper waters. This use applies June 1 through September 30.

Applicable Criteria

Dissolved oxygen criteria protecting the described uses are shown in Table 4.6-1. The methodology for assessing monitoring data against these criteria involves spatial interpolation of fixed site monitoring results to create a 3-D picture of oxygen conditions in thousands of individual grid cells throughout the Bay. Each individual grid cell is then assessed against the criteria. In this way, the volume of water in attainment is calculated for each data collection cruise, allowing for an assessment of criteria on a spatial scale. To account for natural fluctuations over seasons and years, the individual monthly spatial assessments of a three-year time period are aggregated, allowing for an estimate of the frequency of violations. (Note that this contrasts with the six-year time period used in the assessment of DO for non-Bay waters.) The frequency and spatial extent of violations are combined to create a cumulative frequency diagram (CFD) curve, which is examined against an established reference curve.

The dissolved oxygen assessment is based on stations monitored by DEQ, Old Dominion University, Virginia Institute of Marine Science, municipalities, and citizens groups. Details of the assessment procedure can be found in guidance manuals from EPA and DEQ (*Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, EPA 903-R-03-002, April 2003* ; *Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, 2004 Addendum, EPA 904-R-04-005 October 2004*; *Water Quality Assessment Guidance Manual for Y2008: 305(B)/303(D) Integrated Water Quality Report, April, 2007*; and *Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, 2007 Addendum, EPA 903-R-07-003 July 2007*).

Criteria specific to the Shallow-Water submerged aquatic vegetation use (SWSAV) are shown in Table 4.6-2. The criterion of “SAV Acres” was assessed in every segment. The criterion for “Water Clarity Acres” was assessed where data were available (Rappahannock, York and James River systems). The SAV Acres criterion is met by having aquatic vegetation present as measured by annual aerial photography. The Water Clarity Acres criterion is met by having sufficient water clarity present to support the potential for aquatic vegetation to grow (i.e. regardless of whether the submerged aquatic vegetation is actually present). This criterion was created because the water may be clear enough to support

submerged aquatic vegetation, but it may take several years for the areas to re-populate with grasses. A detailed description of the assessment methodology can found in *Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, 2018 Technical Support for Criteria Assessment Protocols Addendum, EPA 903-R-08-001 September 2008.*

The chlorophyll *a* criteria assessed are shown in Table 4.6-3. There are separate criteria applicable to each segment and season, and a spatial-temporal assessment is conducted using a cumulative frequency diagram (see *Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, 2018 Technical Support for Criteria Assessment Protocols Addendum, EPA 903-R-08-001, EPA 903-R-08-001 September 2008*). If either one of the criteria (i.e. spring or summer season) is found to be failing, then the segment is assessed as failing the chlorophyll *a* standard.

Spatial Assessment Units

A general overview of the CBP segmentation scheme that is used for assessment of designated uses is shown in Figure 4.6-3. Not every designated use exists in each segment or necessarily throughout the full extent of the segments in which they exist. Details of where each designated use occurs within each of these CBP segments can be found in *Technical Support Document for Identification of Chesapeake Bay Designated Uses and Attainability, 2004 Addendum*, *October 2004, EPA 903-R-04-006* and *Ambient Water Quality Criteria for Dissolved Oxygen, Water Clarity, and Chlorophyll a for the Chesapeake Bay and Its tidal Tributaries, 2010 Technical Support for Criteria Assessment Protocols Addendum, EPA 903-R-10-002 May 2010*.

Figure 4.6-2 Conceptualized illustration of location of the five Chesapeake Bay tidal water designated use zones.

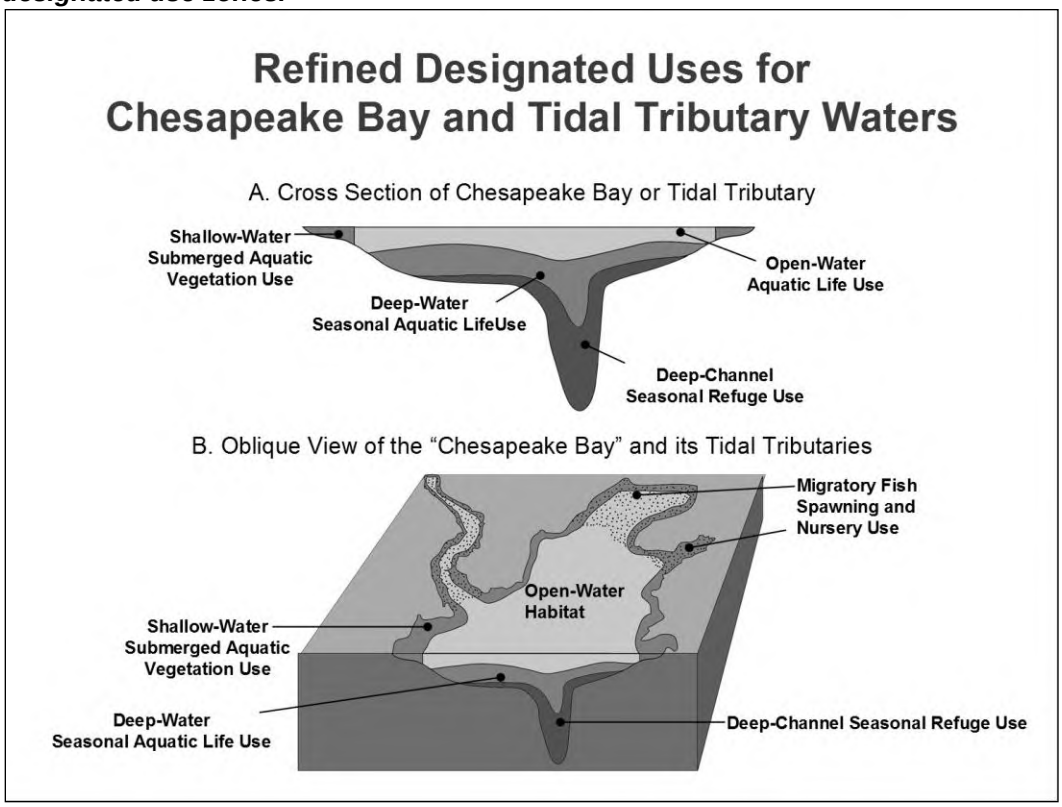


Table 4.6-1 Chesapeake Bay dissolved oxygen criteria

Designated Use	Criteria Concentration/Duration	Protection Provided	Temporal Application
Migratory fish spawning and nursery use	7-day mean $\geq$ 6 mg liter^{-1} (tidal habitats with 0-0.5 ppt salinity)	Survival/growth of larval/juvenile tidal-fresh resident fish; protective of threatened/endangered species.	February 1 - May 31
	Instantaneous minimum $\geq$ 5 mg liter^{-1}	Survival and growth of larval/juvenile migratory fish; protective of threatened/endangered species.	
	Open-water fish and shellfish designated use criteria apply		June 1 - January 31
Shallow-Water bay grass use	Open-water fish and shellfish designated use criteria apply		Year-round
Open-water fish and shellfish use[1]	30-day mean $\geq$ 5.5 mg liter^{-1} (tidal habitats with 0-0.5 ppt salinity)	Growth of tidal-fresh juvenile and adult fish; protective of threatened/endangered species.	Year-round
	30-day mean $\geq$ 5 mg liter^{-1} (tidal habitats with >0.5 ppt salinity)	Growth of larval, juvenile and adult fish and shellfish; protective of threatened/endangered species.	
	7-day mean $\geq$ 4 mg liter^{-1}	Survival of open-water fish larvae.	
	Instantaneous minimum $\geq$ 3.2 mg liter^{-1}	Survival of threatened/endangered sturgeon species.[2]	
Deep-water seasonal fish and shellfish use	30-day mean $\geq$ 3 mg liter^{-1}	Survival and recruitment of bay anchovy eggs and larvae.	June 1 - September 30
	1-day mean $\geq$ 2.3 mg liter^{-1}	Survival of open-water juvenile and adult fish.	
	Instantaneous minimum $\geq$ 1.7 mg liter^{-1}	Survival of bay anchovy eggs and larvae.	
	Open-water fish and shellfish designated-use criteria apply		October 1 - May 31
Deep-channel seasonal refuge use	Instantaneous minimum $\geq$ 1 mg liter^{-1}	Survival of bottom-dwelling worms and clams.	June 1 - September 30
	Open-water fish and shellfish designated use criteria apply		October 1 - May 31

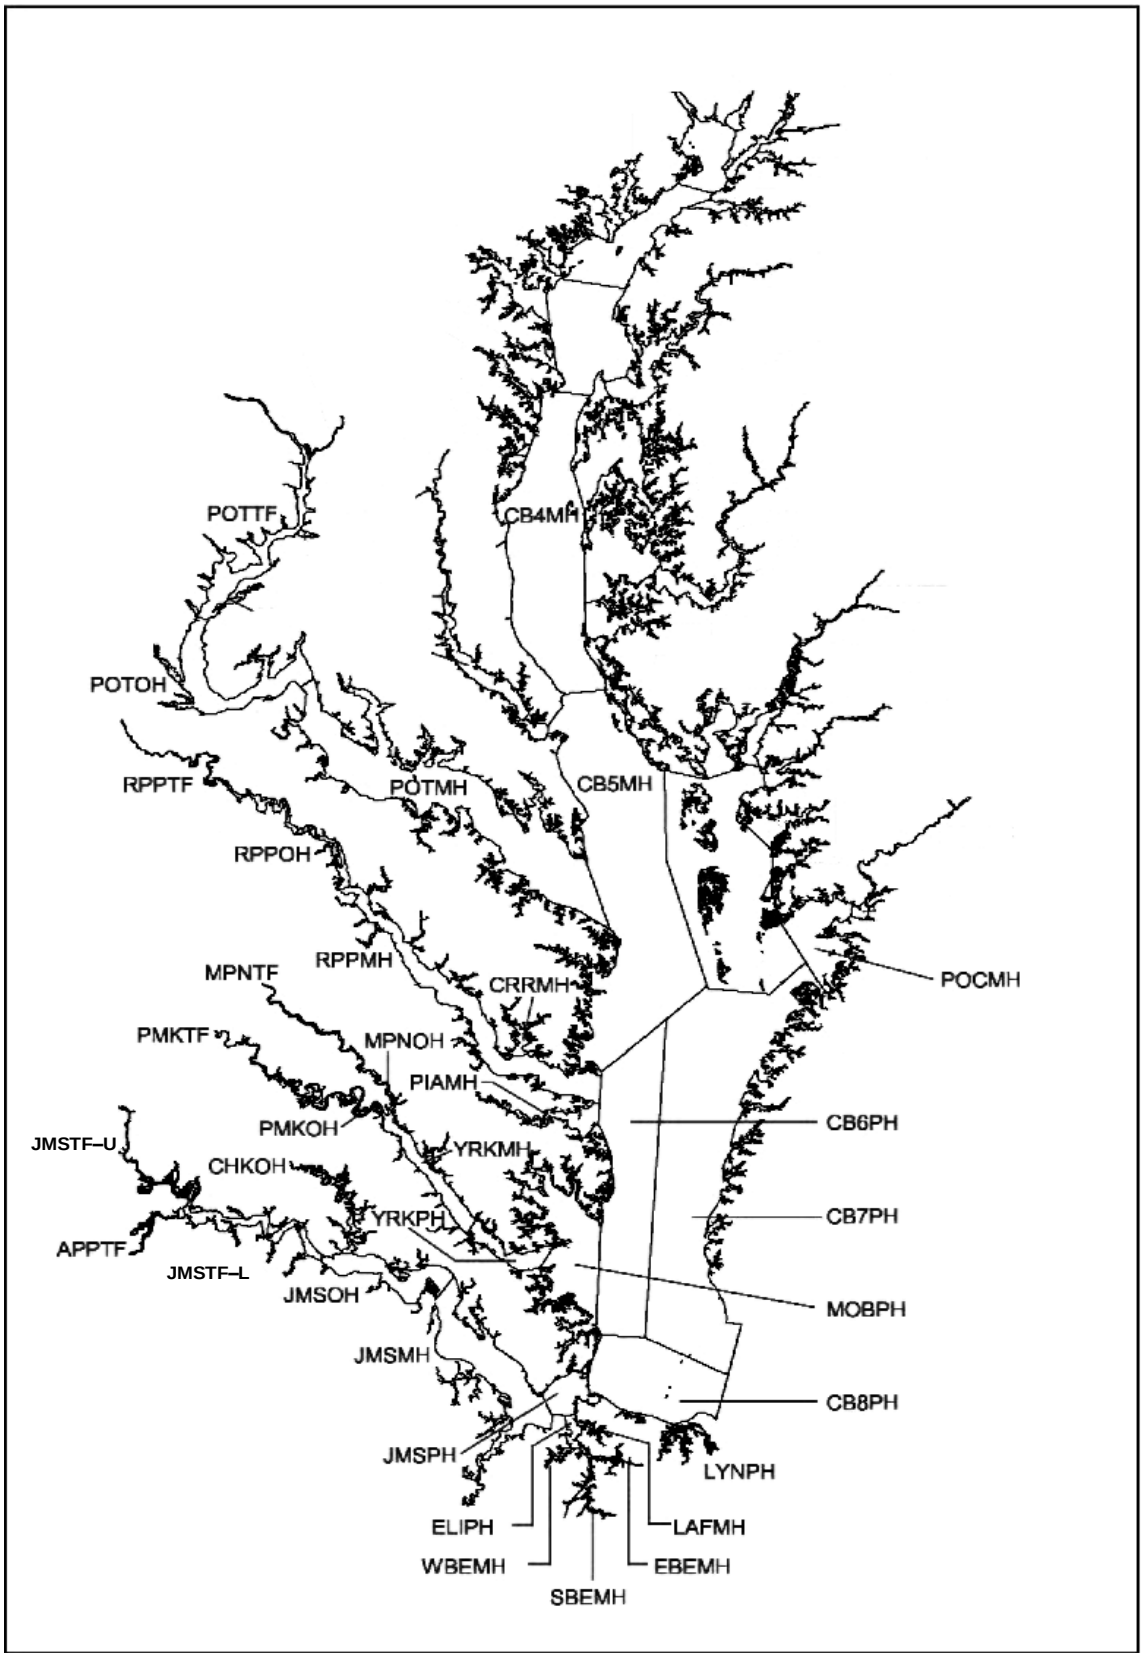
[1] Special criteria for the Mattaponi and Pamunkey rivers are 30 day mean > 4.0 mg/l ;Instantaneous minimum > 3.2 mg/l at temperatures < 29°C; Instantaneous minimum > 4.3 mg/l at temperatures > 29°C.

[2] At temperatures considered stressful to shortnose sturgeon (> 29°C), dissolved oxygen concentrations above an instantaneous minimum of 4.3 mg liter^{-1} will protect survival of this listed sturgeon species.

Table 4.6-2 Summary of Chesapeake Bay water clarity criteria for application to Shallow-Water SAV designated use habitats. Chesapeake Bay program segments are shown in Figure 4.6-2.

Chesapeake Bay Program Segment	SAV Acres[1]	Percent light-through-water[2]	Water Clarity Acres[1]	Temporal Application
CB5MH	7,633	22%	14,514	April 1 - October 31
CB6PH	1,267	22%	3,168	March 1 - November 30
CB7PH	15,107	22%	34,085	March 1 - November 30
CB8PH	11	22%	28	March 1 - November 30
POTTF	2,093	13%	5,233	April 1 - October 31
POTOH	1,503	13%	3,758	April 1 - October 31
POTMH	4,250	22%	10,625	April 1 - October 31
RPPTF	66	13%	165	April 1 - October 31
RPPOH	4	13	10	April 1 - October 31
RPPMH	1700	22%	5000	April 1 - October 31
CRRMH	768	22%	1,920	April 1 - October 31
PIAMH	3,479	22%	8,014	April 1 - October 31
MPNTF	85	13%	213	April 1 - October 31
MPNOH	-	-	-	-
PMKTF	187	13%	468	April 1 - October 31
PMKOH	-	-	-	-
YRKMH	239	22%	598	April 1 - October 31
YRKPH	2,793	22%	6,982	March 1 - November 30
MOBPH	15,901	22%	33,990	March 1 - November 30
JMSTF2	200	13%	500	April 1 - October 31
JMSTF1	1000	13%	2500	April 1 - October 31
APPTF	379	13%	948	April 1 - October 31
JMSOH	15	13%	38	April 1 - October 31
CHKOH	535	13%	1,338	April 1 - October 31
JMSMH	200	22%	500	April 1 - October 31
JMSPH	300	22%	750	March 1 - November 30
LYNPH	107	22%	268	March 1 - November 30
POCOH	-	-	-	-
POCMH	4,066	22%	9,368	April 1 - October 31
TANMH	13,579	22%	22,064	April 1 - October 31

1 = The assessment period for SAV and water clarity acres is the single best year in the most recent three consecutive years. When three consecutive years of data are not available, a minimum of three years within a six-year data assessment window is used.



2 = Percent Light through Water = $100e^{(-KdZ)}$ where K_d is water column light attenuation coefficient and can be measured directly or converted from a measured secchi depth where K_d = 1.45/secchi depth. Z = depth at location of measurement of K_d.

Table 4.6-3 Chlorophyll a criteria for application to open-water designated use habitats in the James River.

Designated Use	Chlorophyll *a* (ug/l)	Chesapeake Bay Program Segment (1)	Temporal Application
Open-Water	10	JMSTFU (James Tidal Fresh Upper)	March 1 - May 31
	15	JMSTFL (James Tidal Fresh Lower)	
	15	JMSOH (James Oligohaline)	
	12	JMSMH (James Mesohaline)	
	12	JMSPH (James Polyhaline)	
	15	JMSTFU (James Tidal Fresh Upper)	July 1 - September 30
	23	JMSTFL (James Tidal Fresh Lower)	
	22	JMSOH (James Oligohaline)	
	10	JMSMH (James Mesohaline)	
	10	JMSPH (James Polyhaline)	

1) See Figure 4.6-3 for locations of these segments.

Figure 4.6-3 Chesapeake Bay dissolved oxygen and water clarity assessment segmentation.

Aquatic Life Assessment Results

Open-Water Designated Assessment

Figure 4.6-4 shows attainment of the 30-day mean criterion for dissolved oxygen (DO) in the Open-Water designated use. Overall summer exceedence rates in impaired segments are not substantially different for this reporting period compared to the last one, but more segments met the criteria during both summer and rest-of-the-year months during the 2012-2014 period than the 2010-2012 period. Segments that currently meet the 30-day mean criterion and failed it previously: the lower tidal fresh and oligohaline segments of the James (JMSTFL and JMSOH), the oligohaline segment of the Pamunkey (PMKOH), Mobjack Bay (MOBPH), and all segments of the Rappahannock River (RPPTF, RPPOH, and RPPMH). Only the oligohaline portion of the Potomac embayments (POTOH) and mainstem segment CB5MH met the 30-Day mean criteria for the last reporting period while failing it for the current one. Attainment of the assessed criteria is achieved in about 22% of the mainstem Bay (i.e. Mobjack Bay, segment CB8PH, and the mesohaline portion of Pocomoke Sound (POCMH)).

The highest DO violation rates occurred in the Southern and Eastern branches of the Elizabeth River—summertime exceedence rates of 44.3% and 40.9%, respectively. Hypoxia during the non-summer months was found in the Lynnhaven River (LYNPH) and both segments of the York River (YRKMH and YRKPH).

Figure 4.6-5 shows an evaluation of chlorophyll-*a* in the James River. All segments failed to meet both spring *and* summer chlorophyll-*a* criteria, except for the oligohaline segment (which attained both).

Deep-Water Aquatic Life Designated Use Assessment

Figure 4.6-5 shows attainment of the 30-day mean criterion for dissolved oxygen in the Deep-Water aquatic life designated use. Much of the designated use was attained--a major departure from what has been observed in the past. Exceedence rates ranged from 0.33% in mainstem segment (CB5MH) to 4.3% in the Southern Branch of the Elizabeth (SBEMH).

Deep-Channel Designated Use Assessment

Figure 4.6-6 shows attainment status of the instantaneous criterion for dissolved oxygen (see inset box). This use exists only in relatively small areas of the Rappahannock mesohaline segment (RPPMH), mainstem Bay segment CB5PH, and the Potomac mesohaline embayments (POTMH). For this assessment, there were only enough data available to assess the first two segments. **For the first time since the Bay criteria were adopted, the Deep Channel sub-use is fully attained in segment CB5MH**.

Shallow-Water Designated Use Assessment

Figure 4.6-7 shows an evaluation of the Shallow-Water submerged aquatic vegetation (SWSAV) designated use. This designated use is attained if there are sufficient acres of submerged aquatic vegetation mapped by annual aerial surveys or if the water is sufficiently clear (i.e. has sufficient "water clarity" acres) so that SAV regrowth is possible. This is because lack of SAV growth may have non-pollutant causes such as insufficient propagule availability, herbivory by turtles and waterfowl, or habitat disruption by cow-nosed rays.

Full attainment of the SWSAV use is present in areas of each of the major estuaries (James, York, Rappahannock and Potomac), but the majority of segments continue to fail SAV acreage goals. As found in previous reporting periods, only nine segments met their respective goals: the Chickahominy (CHKOH), the middle and lower James (JMSOH and JMSPH, respectively), tidal fresh portions of the Mattaponi and Pamunkey (MPNTF and PMKTF), and tidal fresh and oligohaline portions of the Rappahannock and Potomac embayments (RPPTF, RPPOH, POTTF, and POTOH).

The Bay tributaries historically have had relatively little SAV habitat in comparison to the mainstem Bay, where the largest shortfall of vegetation occurs. The open Bay areas with larger shoals had a combined percentage shortfall of 57% (32,0170 acres) for segments CB5MH, TANMH, POCMH, CB7PH, and MOBPH. Forty-six percent (47%) of the overall sum of segment-specific SAV acreage goals was achieved. This means 41,434 acres of SAV needs to be restored before the SWSAV designated use will be met throughout the Bay and tributaries. Alternatively, sufficient water clarity must be present to potentially support this many acres of submerged aquatic vegetation.

Estuarine Benthic Bioassessment

Support status of the general aquatic life use as indicated by benthic community health throughout Chesapeake Bay and its tidal tributaries was performed in cooperation with EPA Region III, EPA Chesapeake Bay Program, Maryland Department of the Environment, Maryland Department of Natural Resources, and the Virginia Department of Environmental Quality. Technical details of the assessment procedure were previously described in 2006 *303(D) Assessment Methods For Chesapeake Bay Benthos, Final Report Submitted to Virginia Department of Environmental Quality, Roberto J. Llansó, Jon H. Vølstad, Versar Inc., Daniel M. Dauer, Michael F. Lane, Old Dominion University, September 2005*.

Due to lack of technical support for data analysis at the EPA Chesapeake Bay Program Office, the 2016 bioassessment could not be performed. The following results are based on the 2014 reporting period (2007 – 2012).

Figure 4.6-8 shows a map of the benthic assessment results. Approximately 241 square miles of the estuarine aquatic life use is impaired. This represents 13% of the total assessed Bay waters, which is down from 77% reported in 2012. The large difference can be attributed to the assessment of mainstem segment CB7PH, which had previously shown a degraded benthic community and currently does not.

Figure 4.6-8 Estuarine Benthic Biological Assessment.

Chesapeake Bay and Tributaries Aquatic Life Use and Sub-use Impairment Listing

The Integrated Report listing methodology addresses the goals of maintaining continuity with previous methodologies, accurately reflecting the assessment results of new uses and criteria and—more importantly--protecting and restoring aquatic life. The listing methodology for the new aquatic life use sub-categories was developed by a Water Quality Criteria Assessment Workgroup involving EPA Region III, EPA Chesapeake Bay Program, Maryland Department of the Environment, Maryland Department of Natural Resources, and the Virginia Department of Environmental Quality. The workgroup's efforts will continue through future modifications as necessary to assure Bay-wide consistency. The main rules for designated use attainment categorization are:

- Aquatic life use is listed as impaired and having a TMDL (i.e. category 4A) if any aquatic life sub-use (i.e. SWSAV, MSN, OW, DW, DC) is not supported.

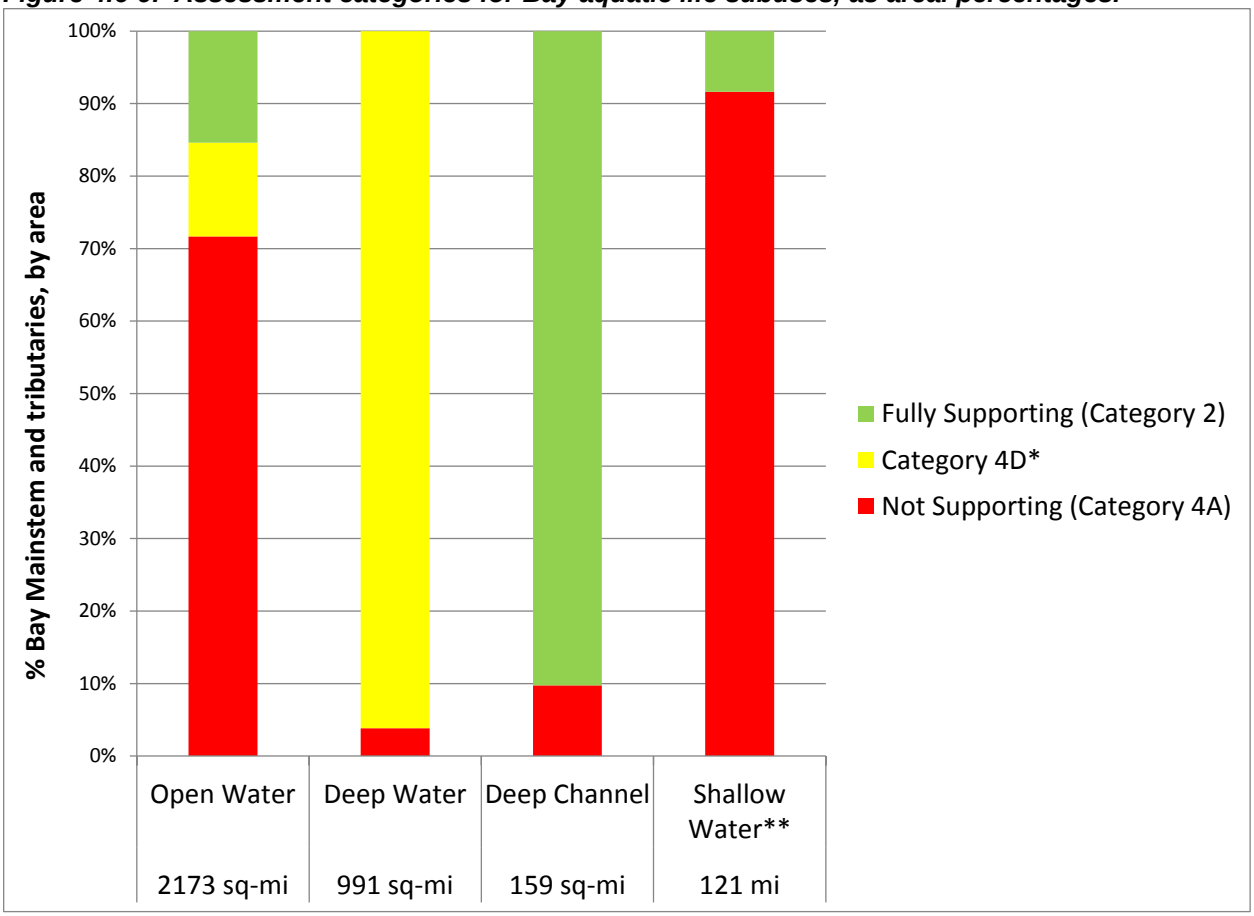
- Waters previously listed as impaired by EPA in 1999 for aquatic life use because of low dissolved oxygen but currently meeting assessed criteria will remain in category 4D[1] until all applicable criteria are assessed. All applicable dissolved oxygen criteria must be assessed and attained in order for a DO-related sub-use (i.e. MSN, OW, DW, DC) to be fully supported for these waters. For additional information on un-assessed criteria, see the section on Future Assessment Refinements (page 187).

- The Shallow-Water submerged aquatic vegetation (SWSAV) use is fully supporting if any of the criteria for this use is met. For example, if sufficient water clarity is present (i.e. "Water Clarity Acres" criterion is met), then the SWSAV designated use is supported regardless of the presence or absence of sufficient submerged aquatic vegetation (i.e. "SAV Acres" criterion is not met). This is because there can be many non-pollutant causes for the lack of SAV acres such as lack of propagule availability, herbivory by turtles, waterfowl, etc. or habitat disruption by cow-nosed rays.

[1] A waterbody is assessed as category 4D when a part(s) of a water quality standard is attained for a pollutant with a TMDL, but the remaining criteria for the standard were not assessed due to insufficient information. This only to be applies to dissolved oxygen in tidal waters of the Chesapeake Bay.

Aquatic Life Use Assessment Database Summary for Chesapeake Bay Waters

Figure 4.6-9 presents aquatic life designated use and sub-use support for the Chesapeake Bay and its tidal tributaries as summarized from the Assessment Database. The Deep Water Aquatic Life Use subcategory (DW), Deep Channel Aquatic Life Use subcategory (DC), Shallow Water Aquatic Life Use subcategory (SWSAV), and Aquatic Life Use sizes in this chapter are different than what is presented elsewhere in this chapter. This is due to the complex spatial nature of the Bay uses and limitations of the Assessment Database (ADB). A few of the confounding issues and differences between results in this chapter and area summarizations in other chapters created from ADB are listed below.



- The area of DW and DC is inaccurate in ADB. Area of DW and DC reported in this chapter vary in square mileage size within assessment units and between reporting periods due to the naturally varying depth of pycnoclines. However, DW and DC area in ADB can only be reported as existing throughout the complete assessment unit.

- The area of SWSAV use is inaccurate in ADB. The SWSAV designated use exists only within the area defined by the SAV acres criteria. For example, CBP Segment CB5PH has an SAV acres criterion of 7,633 acres (see Table 4.6-2) therefore the area of SWSAV designated use for this segment is 7,633 acres (i.e. 11.9 square miles). However, within ADB the size of SWSAV use within this segment can only be reported as the complete area of the assessment unit (i.e. 215 square miles). The figures reported in this chapter are therefore more accurate.

- Related to the above, the area of impairment for aquatic life use within ADB is often incorrect. For example, segment CB8PH failed the SWSAV use, so the segment also fails the aquatic life use. The area of SWSAV use within this segment is only 11 acres (0.02 square miles), making the accurate area of aquatic life use impairment only 0.02 square miles. However, within ADB the area of aquatic life use can only be reported as the complete area of the assessment unit (48.4 square miles). The figures for impairment area reported in this chapter are more accurate than what appears in ADB.

- This chapter reports only the aquatic life use and sub-use impairments due to dissolved oxygen, water clarity, chlorophyll, and benthic community assessments. Some waters have met all the assessed criteria for these parameters, but may be impaired in ADB for aquatic life due to other parameters (e.g. pH, chloride, bacteria, toxics, etc.). Aquatic life use impairments due to these other parameters are not reported in this chapter.

Figure 4.6-9. Assessment categories for Bay aquatic life subuses, as areal percentages.

* Category 4D applies to waters that meet assessed DO criteria, but which are required to meet all applicable DO criteria before they can be assessed as fully supporting (category 2).

** 47% of the total SAV acreage goal (121 sq-mi) was attained. However, only segments that have met their respective goals are assessed as fully supporting (category 2). The sum of their goals represents 8% of the total SAV acreage goal.

Future Assessment Refinements

This is the sixth report to present assessment of the designated uses in the Chesapeake Bay and its tidal tributaries. Much progress has been made in developing realistic and appropriate designated uses, associated criteria, and assessment protocols for the Chesapeake Bay and its tidal tributaries. Continued refinement for future assessments is summarized below. To ensure consistency throughout the multi-State Chesapeake Bay system, most of these issues will be resolved through the Water Quality Criteria Assessment Workgroup involving EPA Region III, EPA Chesapeake Bay Program, Maryland Department of the Environment, Maryland Department of Natural Resources and the Virginia Department of Environmental Quality.

Assessment of currently un-assessed designated uses and criteria

Of the five aquatic life sub-uses, this chapter reports only on conditions for the Open-Water, Deep- Water, Deep-Channel, and Shallow-Water submerged aquatic vegetation sub-uses. It is anticipated that future reports will assess the remaining aquatic life sub-use of "Migratory and Spawning Fish". Also, only a limited suite of dissolved oxygen criteria for each sub-use were assessed, these being 30-Day average for dissolved oxygen in Open- and Deep-Water uses and the instantaneous minimum for the Deep-Channel use. Many other dissolved oxygen criteria were not assessed (e.g. 7-day, 1-day, and instantaneous minimum criteria). These limitations on assessments of designated uses and criteria are due to the lack of EPA-approved assessment protocols.

Refinements to assessment protocols

While DEQ believes the protocols performed for this assessment are valid, the following issues may be examined in more detail for future assessments:

a. Refinements in spatial interpolation tools.

Part of the assessment protocol involves spatial interpolation of data to create a 3-dimensional depiction of oxygen conditions throughout a waterbody segment. The software used for performing this step in this assessment may be refined and updated to enhance interpolation for future assessments.

b. Refinements in statistical determination of attainment.

Data are assessed after interpolation for criteria exceedences using a reference curve to determine waterbody attainment. The assessment was based on either EPA-published reference curves or used a default 10% reference curve if a published one was not available for a specific aquatic life sub-category (e.g. deep water). It is possible that new reference curves developed by EPA could be adopted into Virginia water quality standards and used in future assessments. Also, there may be future efforts to explicitly incorporate statistical measures of uncertainty into the reference curve attainment process.

Table 4.6-4 shows a summary of the most recent long-trend analysis performed by the Dauer lab at ODU (report available by request). This analysis indicates that nutrient concentrations in the mainstem and many of the tributaries segments are generally improving, while water clarity (as measured by secchi depth) shows a degrading trend overall. Where a significant trend was detected for total suspended solids, it was usually in the "improving" direction. Few discernible trends were detectable in chlorophyll *a,* benthic community integrity, and dissolved oxygen concentrations.

CHAPTER 5 NONPOINT SOURCE ASSESSMENT, PRIORITIZATION, AND ACTIVITIES

This section of the Virginia Water Quality Assessment 305(b) Report includes an assessment of nonpoint source (NPS) pollution potential at the 6th level (12-digit) hydrologic units of the National Watershed Boundary Dataset (NWBD) (hereafter referred to as either hydrologic units, or just units). It also includes indicators for prioritizing NPS corrective actions at the hydrologic unit level and a summary of NPS reduction activities currently underway. It has been prepared by the Virginia Department of Conservation and Recreation (VADCR) and the Virginia Department of Environmental Quality (VADEQ) to provide a comparative evaluation of the state's waters, on a hydrologic unit basis. This comparative evaluation can be used to target limited resources and funds for NPS pollution protection activities to where they are most needed. The key results of the assessment include quantification of nutrient and sediment loads and a ranking of hydrologic units as high, medium or low based on those loads. The ranking is presented in a series of maps and tables for each major source sector such as; agriculture, forestry, and urban, with an additional series of maps representing the overall or combined ranking.

The 2016 NPS Assessment and Prioritization study summarizes existing sources of information, as referenced, and data provided by the following organizations: VADCR, VADEQ, Virginia Department of Forestry (VDOF), U.S. Department of Agriculture - Natural Resources Conservation Service (USDA-NRCS), local Soil and Water Conservation Districts (SWCDs), the Department of Biological Systems Engineering (BSE) at Virginia Tech (VT), the Virginia Department of Health (VDH), the Virginia Department of Game and Inland Fisheries (VDGIF), the Virginia Department of Mines, Minerals, and Energy (VDMME), the Center for Environmental Studies (CES) at Virginia Commonwealth University (VCU), the US Environmental Protection Agency (EPA), the Chesapeake Bay Program (CBP), the U.S. Geological Survey (USGS), the Multi-Resolution Land Characteristics Consortium (MRLC), Conservation Technology Information Center (CTIC), the US Department of Interior – Census Bureau, the American Community Survey, and the Climate Forecast System Re-analysis (CFSR).

There are four major components to the 2016 NPS Assessment and Prioritization study - potential pollutant loadings, water quality impairments, measures of biological health, and NPS reduction activities. The main focus of this chapter is the determination of potential loadings of total nitrogen (TN), total phosphorus (TP), and total sediment (TS), hereafter referred to as NPS pollutants, by hydrologic unit and agricultural, urban, and forest generalized land use classes. The evaluation of hydrologic units by aquatic species' health represents water quality measures not necessarily related to the potential NPS pollutant loads. In order to prioritize clean-up and protection activities, hydrologic units of prime importance for the protection of public surface water supplies were also determined. Details of these components follow.

NPS POLLUTION LOADINGS

The NPS Assessment estimation of pollutant loadings is based on a calculation of the estimated edge of stream (EOS) loadings of nitrogen, phosphorus, and sediment per hydrologic unit using the Generalized Watershed Loading Functions (GWLF) model.

The estimation of loads of NPS pollutants as a basis for assessing water quality by hydrologic unit is consistent with Virginia's participation as a partner with the EPA's CBP in the calculations of NPS pollutant loads using the Chesapeake Bay Watershed Model (CBWM). Although Virginia uses CBWM results (particularly in CBP related activities), they have only been obtainable for that portion of Virginia that is in the Chesapeake Bay Watershed (James, York, Rappahannock, Potomac, and Bay Coastal basins). Other state programs can benefit from having measures similar to the CBWM loads but for the non-Bay portion of the state. As has been done since 2002, Virginia has produced statewide NPS pollutant load results similar to those of the CBWM by using the GWLF model[1].

[1] GWLF was chosen because it was configured for continuous simulation and could produce EOS loads based on land-based loadings, fate, and the transport of pollutants as does the CBWM. Both models also simulate seasonal variations, include both surface and subsurface components, and can represent both dissolved and particulate forms of pollutants. The GWLF model used in the 2016 assessment is an update of the model developed for the 2014 and previous assessments.

NPS pollutant load estimations were performed by taking into consideration the relevant best management practice (BMP) installations in Virginia over the previous sixteen year period (1998-2014) by VADCR, VADEQ, VDOF, USDA-NRCS, local stormwater management agencies, and private nutrient management plan writers. Table 5-1 lists the generalized land use classifications and details the contributing specific land uses utilized for this assessment.

Table 5-1 Descriptions of Nonpoint Source Assessment Generalized Land Uses

Nonpoint Source Assessment Land Classifications	Source Data Descriptions
Forest	Pine, Hardwood, Mixed Harvested/Disturbed Forest
Agriculture	Crop: Conventional Tillage, Conservation Tillage, Bare Soil, Hay Livestock: Unimproved Pasture, Pasture Cattle-Grazed, Pasture Poultry Litter Applied, Pasture/Forest/Field Manure Applied
Urban	Impervious (Pavement, Sidewalks, Roof Area, Compacted Areas, High Density Residential) Pervious (Grassland, Low to Medium Density Residential, Industrial, Bare Soil)

As would be anticipated, there are loading estimation changes between the 2014 and 2016 assessment calculations. These changes are the result of updated and improved data along with model recalibration and corrections made to the model code.

For consistency with previous NPS assessment reports and maps and with the manner in which this data is used, the ranking of hydrologic units for the NPS pollutant unit area load (UAL) components for the 2016 NPS Assessment has maintained the division of UALs into previously used categories - the highest 20% of the values for each component are classified as high, the next 30% are classified as medium, and the remaining 50% are classified as low. This ranking methodology applies to the NPS pollutant loads only. These range definitions are not absolute, since units with equal or very similar loading values were not divided into different classes.

Table 5-2 reports the final statewide loadings by pollutant and the amount of land in Virginia by general land use class. Loading values in this table reflect the loads after the reductions are applied from active BMPs installed over the previous sixteen years. More information regarding model development, land use classification details, and methodology for estimating pollutant loading per land use and per pollutant, is provided in the final section of this chapter.

Table 5-2 2016 Statewide NPS Pollutant Loads – Post BMP Reduction

	Units	Agricultural Class	Urban Class	Forestry Class	Other (Barren, Extractive, Channel Erosion, Septic)
Total VA Land Area #	Acres	5,722,303	2,528,960	16,714,994	
%of VA Land	%	22.83	10.09	66.69	0.39
Total Nitrogen	10^6 Kg/year	10.70	5.42	7.77	
%of all NPS N ^	%	33.92	17.20	24.63	24.25
Total Phosphorus	10^6 Kg/year	1.09	0.51	0.51	
% of all NPS P ^	%	49.13	22.98	23.04	4.85

Total Sediment	10^6 Kg/year	1,278.27	0.12	1,134.9	
% of all NPS S ^	%	41.96	4.04	37.26	16.74

Value does not include acres of non-forested wetlands and barren land (see Table 5-7).
^ Includes loads from barren, channel erosion, and extraction.

Agricultural NPS Pollution Loads

Agriculture is a large and diverse industry in Virginia and accounted for almost 23% of Virginia's land use in the year being assessed. While this percentage is significantly lower than the national average and continues to decline in Virginia, agricultural activities remain the most significant source of nonpoint source pollution in the state. As shown in Table 5-2 and as the current and all past assessment model results suggest, agricultural land in Virginia contributes NPS pollutant loads in greater proportion to the area they comprise than do the other land use classes.

Nonpoint source pollutants from agriculture originate from several different sources with different associated impacts. Deposition to agricultural lands in the form of fertilizers and animal manures affect water quality when they reach groundwater reserves, are directly deposited to streams, or are washed into surface waters during rain events in either a dissolved state or with eroding soils. These pollutants include pathogens as well as nutrients. Farming practices can contribute to or retard runoff and can certainly affect the amount of soil lost from fields which can potentially end up in water features.

This assessment estimated the nutrient and sediment loads from agricultural areas but not pathogen loadings. Factors in this assessment which affect the amount of nutrient loads reaching water from agricultural lands include the soil erodability, types of agricultural practices, types and numbers of farm animals, land cover, stream density, rainfall, seasonal variations in plant growth and nutrient applications, existence and type of agricultural BMPs, soil saturation, and slope.

The ranked UALs by hydrologic unit of nitrogen, phosphorus, and sediment from agricultural land uses are displayed in Figures 5-1, 5-2, and 5-3 respectively. The rankings are also listed in Table 5-3

There are a few factors that are specific to changes in loadings, and thus ranks, of the agricultural NPS pollutants between the current and past assessment products. Perhaps the most significant factor is that the model itself was recalibrated with new data, parameters, and procedures. Otherwise, the updating of the land use is usually the primary contributor to changing loads. Additional factors are noted below.

Urban NPS Pollution Loads

Around 10% of the land in Virginia was considered urban for the year being assessed. Urbanized land produces NPS pollutants as the result of precipitation washing nutrients, sediment, and other substances from the impervious surfaces found in these areas. The sources of these surface contaminants include: air and rain deposition of atmospheric pollution; littered and dirty streets; traffic by-products such as petroleum residues, exhaust products, heavy metals and tar residuals from the roads; chemicals applied for fertilization, control of ice, rodents and other pests; and sediment from construction sites. Improper industrial, commercial and domestic hook-ups to storm sewers also contribute various pollutants to waterways, as do inadequate and/or improperly maintained sewage disposal systems both for municipalities and individual homes.

This assessment estimated only the nutrient and sediment loads from urban areas and no other urban NPS pollutants as described above. Factors that affect the amount of surface and channel erosion loads reaching water from urban lands include the degree of imperviousness of the urban land use, impervious area NPS pollutant build-up rates, stream density, rainfall, septic system use, direct discharges, soil saturation, and slope.

The main factors to changes in loadings, and thus ranks, of the urban NPS pollutants between the current and past assessment products are the same as for agricultural loads. These were updated land use, as well as updated model data, parameters, and procedures. Also of relevance septic loads were excluded from the reported urban load, as they had been in the past. This is because septic loadings are not

exclusive to the urban environment and so they were simulated as an individual loading source in this assessment.

The ranked UALs by hydrologic unit of nitrogen, phosphorus, and sediment from urban land uses (as described in Table 5-2) are displayed in Figures 5-4, 5-5, and 5-6 respectively. The rankings are also listed in Table 5-3. Urban load measures are based on pollution potential and do not compensate for many of the urban runoff control measures that may be in place in some areas. Such reduction measures are primarily installed by the private sector.

Forestry NPS Pollution Loads

Almost 67% of Virginia's land area was forested in the year being assessed. Forestland in general produces lower NPS pollutant loads[2] per unit area than other land uses. Certain forest disturbing activities such as tree harvesting, site preparation, and reforesting, however, do make a load contribution. As Table 5-2 shows, these activities contribute more to the sediment load than they do to other NPS pollutants.

Forestland can be harvested as part of a land use change such as residential development, clearing for agricultural fields, or surface mining. Due to the similar spectral signatures in classified land cover imagery of these land activities, as well as those of non-temporary land covers such as bare rock and beaches, it can be difficult to discern them from one another without other associated data. Fortunately, the VDOF tracks forest harvesting activities to facilitate the proper management of Virginia's forest resources relative to water quality.

Whereas agricultural activities operate on a yearly or seasonal cycle on agricultural lands, a single cycle of forest harvesting, site preparation and reforestation occurs over many years. Due to temporal and spatial overlap in silvicultural cycles, measurement of these forest disturbing activities in this assessment is more of a snapshot than a trend. As such, the ranking of hydrologic units for forest based loads varies more between NPS Assessments for forest harvesting units than do the loads of other land use classes when model code and parameters are kept constant.

Factors in this assessment that affect the amount of loads reaching water from forestlands include soil erodability, existence of disturbed forestlands, stream density, rainfall, existence and effectiveness of forest (silviculture) BMPs, soil saturation, and slope.

The ranked UALs by hydrologic unit of nitrogen, phosphorus, and sediment from forestland uses are displayed in Figures 5-7, 5-8, and 5-9 respectively. The rankings are also listed in Table 5-3.

The factors most responsible for the changes in loadings, and thus ranks, of the forest NPS pollutant loads in this assessment are the same as for agriculture and urban uses. Additional factors include updated forest harvesting information from VDOF, and improved accounting of silviculture BMPs effectiveness.

NPS Pollution Loads of Other Land Uses

Extraction and non-urban barren lands have not been lumped into any of the output land use classes with regard to reporting loads or unit area loads (see Table 5-2). Therefore, they do not influence the ranking of units for any of the specific land use load classes. Likewise, loads from the non-sewered population and channel erosion are not reported in any specific land use class load.

Using resource extraction spatial data from the VDMME helped isolate true extraction activities from reforesting sites, urbanization, or other land disturbing activities. The spatial distribution of extraction land use was used in conjunction with county level recordings of extraction activity.

[2]Airborne nutrient pollution is accounted for as part of the load of the land use it falls upon. The majority of the airborne nutrient load falls on forestland in Virginia and is therefore associated more with forestland than with other uses.

Approximately 4.85% of the phosphorous, 24.25% of the nitrogen, and 16.75% of the sediment load in the 2016 NPS Assessment was associated with loads from the non-sewered population, channel erosion, barren, and extractive land uses. The largest contributor of this group is the nitrogen load from failing septic systems and straight pipes (untreated). The most significant extraction use loads occurred in the Big Sandy basin. In general, barren land only contributed minor loads.

Total Loads by NPS Pollutant

Calculated total nitrogen, total phosphorus, and total sediment unit area loads from all land uses combined, including the other uses noted above, are displayed in Figures 5-10, 5-11, and 5-12, respectively and listed in Table 5-3. Total nitrogen is composed of septic nitrogen, groundwater nitrogen, dissolved nitrogen from various land uses, wash-off of nitrogen from impervious surfaces, and sediment-attached nitrogen. Total phosphorus is composed of septic phosphorus, groundwater phosphorus, dissolved phosphorus from various land uses, wash off of phosphorus from impervious surfaces, and sediment attached phosphorus. Total sediment is the sediment yield from all land uses and instream erosion.

The summing of NPS pollutant loads by land use into total NPS pollutant loads in this NPS assessment is simply the addition of values with equivalent units (kg/ha/yr of nitrogen or phosphorus, Mg/ha/yr of sediment). Accordingly, the relative weight of the estimated NPS pollutants coming from one land use versus another is directly comparable. This comparison shows that NPS pollutants from agricultural lands dominate the total NPS pollutant loads although barren lands can be heavy contributors where they occur in some concentration.

IMPAIRED WATERS

In accordance with US EPA Clean Water Act (CWA) guidance and protocol, the VADEQ assembled a list of the water quality limited riverine, lacustrine, and estuarine waters of Virginia in 2014 (303d report). That list and associated assessment geodatabase of water quality limited waters are the basis for the impaired waters portion of the 2016 NPS Assessment. Similar to the rankings of estimated pollutant loads, the impaired waters ranking presents a series of maps depicting, by hydrologic unit, the relative proportion of waters that appear to be impaired due to nonpoint source pollution.

Among the many defined attributes in the impaired waters assessment geodatabase are the names of the impaired waters, the beginning and ending spatial limits of the impaired portions, impairment causes, and impairment sources. Following is a brief overview of the generation of this prioritization ranking list and the evaluation of NPS impacted waters, a subset of this assessment geodatabase. Included first, were all the waters identified by VADEQ staff as having NPS related sources. Additionally, this ranking included those impaired waters which did not list any point source related causes or listed sources as unknown, provided visual inspection of high resolution imagery of the surrounding watershed(s) could corroborate that the source was likely NPS (i.e. urban or natural)[3]. Excluded from the ranking list are those waters listed as impaired for toxics or occurring in primarily estuarine influenced areas.

Waters in the impaired waters layer that are suspected of being impaired due to nonpoint sources were divided by the hydrologic unit boundaries into segments to allow for the summation of impaired water lengths or areas by these units. The same process was performed on all waters in the state and determined the total available miles of riverine, acres of lacustrine, and square miles of estuarine waters per hydrologic unit that occur for comparison against the impaired portions.

Whereas the 2016 NPS Assessment focuses on nutrients and sediment, most of the NPS impaired waters from the 2014 303(d) report are listed due to the existence of pathogens. Total Maximum Daily Load (TMDL) studies have shown that pet wastes can have a role in high pathogen counts in some urban streams. Concentrations of wildlife can have a similar effect in various land use / land cover settings.

[3] This included all fecal causes of unknown sources since approximately 90% of non-urban fecal problems are surmised to be due to agricultural or natural animal loadings. Similarly, because about 85% of benthic impairments are believed to be sediment related, and because VADEQ personnel are more likely to know and document point sources of benthic impairments, all benthic impairments of unknown sources are considered to be NPS related. Impairments with nutrient sources were also included.

Likewise, human wastes, arising from the existence of straight pipe disposal, failing septic systems, or malfunctioning water treatment plants and their permitted collection system infrastructure, can all contribute to the impairment of waters due to high levels of pathogens. Based on TMDL studies completed to date, a significant number of the waters impaired due to the existence of pathogens are believed to be impaired because of farm animal wastes.

The number of farm animals by type and by unit is part of the nutrient load calculation, since most farm animal wastes are recycled back to the ground by the animals or in a more controlled mode by farmers who want to fertilize fields and/or remove wastes from confined animal sites. The controlled dispersal of wastes is a goal of nutrient management planning and a practice that DCR cost-shares with farmers to implement. The fencing off of stream banks and construction of alternative water sources are two such practices, in this case designed to keep livestock out of and away from streams so as to avoid sediment loading from eroded stream banks and also avoid direct deposition of manure and its associated pathogen load.

The following rankings of hydrologic units by water regime consider only non-shellfish NPS-associated impairments.

Riverine Impairments

Summed lengths of NPS impaired riverine water features in 2014 as miles per hydrologic unit were compared to the total miles of riverine systems available per unit at the same scale[4] to determine the percentage of the total available riverine water miles per unit that were NPS impaired. The ranking of this value is based on the value itself and not on a pre-set distribution of the range of calculated percentage values. The rankings of units for impaired riverine waters are displayed in Figure 5-13 and listed in Table 5-3.

Estuarine Impairments

Most of the impaired main-stem estuarine water bodies in Virginia have listed impairment causes that are not considered to be due to practices occurring in the immediate units that they flow through. There may be, in fact, very little land associated with some of these units. Estuarine waters are also tidal and may show pollution effects from multiple areas, even if they are not main-stem estuarine water bodies. For these reasons the estuarine waters are not being used to rank the hydrologic units in which they pass through in this assessment. Although there are NPS impaired estuarine waters it is difficult to associate them with specific upland NPS pollutant sources.

Lacustrine Impairments

Summed areas of impaired lacustrine waters in 2014 as acres per hydrologic unit were compared to the total acres of lacustrine waters available per unit to determine the percentage of lake waters in a unit that were impaired. Although the land area of these units can be a source of NPS pollutants, so too can the incoming streams.

The ranking of this value is based on the value itself and not on a pre-set distribution of the range of calculated percentage values. The vast majority of the hydrologic units in Virginia contained no impaired lake or reservoir waters in 2014. However, most of the remaining units had very high percentages of impaired lacustrine waters. This distribution is in part due to the decreased unit sizes of the 6th level NWBD units but also due to the call regarding their impairment source. The rankings of hydrologic units for impaired lacustrine waters are displayed in Figure 5-14 and listed in Table 5-3.

BIOLOGICAL HEALTH

Additional components for evaluating the effects of nonpoint source pollution include the VDH public surface water sources and their protection zones and an evaluation of the health of aquatic species

[4] In 2014 the scale was 1:24,000, augmented by the inclusion of smaller streams designated as impaired.

in the state's waters conducted by the Center for Environmental Studies at VCU. These components provide an additional means to prioritize water quality protection - the protection of the sources of public drinking water and of natural aquatic communities respectively.

Public Source Water Protection

As part of their Source Water Area Protection (SWAP) Program, the VDH determined the area upstream of public surface water intakes that must be investigated for threats to water quality. The most immediate area of their concern is referred to as the Zone 1 for each intake. Zone 1 areas extend out to a five mile radius upstream from a water supply intake or five miles around a lake containing an intake, without crossing watershed boundaries except those upstream. The population served by an intake, provided by VDH, and the portion of a hydrologic unit that is within a Zone 1 area has been used by VADCR to calculate the concentration of persons served per unit by these public surface water supplies. The concentration values serve as a measure of the importance of high water quality by hydrologic unit for public drinking water supply protection.

Concentration values are the summation by hydrologic unit of all Zone 1 areas or combinations of Zone 1 areas in that unit times one one-thousandth of the effective population each serves. In cases where a municipality owned several intakes, the single recording of population served was divided amongst each intake to create an effective population served. In cases of overlapping intake reaches the effective population of each reach was summed for the portion of overlap.

The categorized values and rankings for indicating concentration by unit are displayed in Figure 5-15 and listed in Table 5-3. Unlike the NPS loading variables in this assessment, where high ranked units represent units of concern, the high ranking public source water units are just units with a greater need for water quality protection. A significant amount of their area lies immediately upstream from surface water intakes that are used extensively for public drinking use by many people.

The vast majority of hydrologic units contained no Zone 1 protection zones or portions of Zone 1 protection zones. Of those with some Zone 1 content, the majority had low levels (< 10) of the calculated measure for concentrations of people served within a watershed. Of the remaining units, a few had significantly higher value measures (> 100) and were therefore classified as having a "Very High" need for source water protection. The rest were divided amongst a moderate category (10-30) and a high category (30-100).

Aquatic Species Measures

The presence or absence of certain aquatic species can serve as an indication of the overall quality of a particular waterway. They can also indicate where the most biological damage can occur from water quality degradation. Accordingly, the NPS Assessment and Prioritization study provides a ranking of hydrologic units for stream-dependent living resources (including fish, mollusks, and crayfish) using a multi-metric index calculated by the CES at VCU as part of their Interactive Stream Assessment Resource (INSTAR).

These indexes (referred to as the mIBI - a modified version of the Index of Biological Integrity) are calculated by the CES using databases originally developed by VADCR, the VDGIF, and VCU[5]. More than 162,000 database records from over 2000 aquatic collections have been gathered since INSTAR's Inception. As a result it is possible to calculate a mIBI value for more than 93% of the 6th level units of the NWBD. An equally beneficial result from having more records available for any unit is the decreased likelihood of a false prioritization indication based on minimal information.

By associating a hydrologic unit code with each of the stream segments for which aquatic species information was available in the various databases, metric scores by unit were developed for each of six metrics. These metrics are as follows:

[5] More information about the mIBI and the other components of INSTAR can be found at http://gis.vcu.edu/instar/.

Metric 1 Number of Intolerant Species: refers to the total number of unique water quality intolerant species found in a unit.

Metric 2 Native Species Richness: refers to the number of indigenous (local) species present in a unit.

Metric 3 Number of Rare, Threatened and Endangered Species: refers to the number of species that are considered rare, threatened or endangered due to their low population levels that are present in a unit.

Metric 4 Number of Non-indigenous Species: refers to the number of non-native species present in a unit. These are introduced species that would not normally be found in this particular location.

Metric 5 Number of Critical Species: refers to the number of species found in a unit that are considered critical because of some important role that they play, such as being a food source or a major recreational fishery.

Metric 6 Number of Tolerant Species: refers to the number of species found in a unit that are tolerant to degraded stream conditions and can survive even in these sub-optimal conditions.

A score of 0 – 5 was assigned by the CES for each metric based on the metric's values. In general, high metric values were assigned high metric scores - indicative of high stream health. A score of zero was given if insufficient data were available. Of the 1251 hydrologic units, 86 (7%) were assigned a zero for this reason. Metrics 4 and 6 were reversed in the scoring, since a low value for either of these metrics would indicate high stream health. Therefore a high metric score was given for low metric values for these two metrics. Lower values are more desirable in metrics 4 and 6 because a high number of non-native species and/or a high number of species that are tolerant to stream degradation are less desirable characteristics for a stream.

Scores for each metric for each unit were totaled to give an overall total mIBI score per hydrologic unit. These summed scores per hydrologic unit were then tiered relative to the summed scores of the other units in the same basin by assigning a category value of High (score of 5), Medium (score of 3), or Low (score of 1) on per metric per basin basis. The resulting total mIBI scores are used to place each hydrologic unit into ranked categories reflecting biotic integrity and resource importance.

Since there were six metrics and a maximum score of 5 could be obtained for each metric, the overall maximum score a unit could receive was 30 (6 x 5). Fewer than 8% of the units (100) are considered to have very high biodiversity, with total mIBI scores of 20 or more. Another 198 units have total mIBI scores of at least 18. At the other end of the spectrum, 24% of the units (301) with sufficient data have total metric scores of 12 or less – indicative of low biodiversity. These units most probably contain waters with some degree of degradation.

The categorization of the mIBI scores by hydrologic unit is displayed in Figure 5-16, and listed in Table 5-3. In this figure and table, high mIBI scores equate to areas of high biotic integrity. Whereas, low mIBI ranked units represent units of concern in regard to low water quality based on aquatic species measures, high ranked units represent areas of importance for the protection of the state's streams with exceptional biodiversity. There has been very little change in total mIBI scores over the past few years.

While the maintenance or enhancement of water quality for the protection of all native aquatic life is the preferred goal, these aquatic species priorities should help direct NPS pollution mitigation efforts and other water quality improvement projects toward hydrologic units with the most important aquatic resources.

COLLECTIVE USE OF RANKINGS

The twelve rankings assigned to hydrologic units for NPS pollutants by land use class, the two rankings for impaired waters occurrence, and the two rankings of units for biological health can be used in various combinations to evaluate statewide conditions and prioritize NPS reduction activities. Which measures are included in each prioritization process, and how one weighs in comparison to another, depends on the activity to be prioritized. For instance, VADCR uses the agricultural NPS pollution

rankings as variables in the targeting of agricultural best management practices (see Agricultural Cost Share Program below).

There are several considerations to keep in mind when constructing prioritization processes using these rankings. Perhaps the most important is that some factors are measures potentially being produced at the hydrologic unit of interest, such as the NPS pollutant loadings. Other measures reflect existing conditions at the unit of interest, such as aquatic species health, and may in part be due to activities occurring in upstream units. The source water concentration values directly account for the upstream effect by virtue of their being based on a designated upstream zone.

Another consideration is the possible incorrect inference of cause and effect. Waters in a hydrologic unit may be impaired due to nonpoint sources but the cause of these waters being listed as impaired is not necessarily related to the nitrogen, phosphorus, and sediment that are potentially being loaded to them in either the unit of concern or upstream of it. Likewise point source loadings can be the reason for the streams in a unit to collectively produce a low mIBI score and aquatic species rank.

In the 2016 NPS Assessment and Prioritization some units have been flagged for conditions that can be determined by comparing the rankings of measures in this report. The flags have been entered into Table 5-3. The conditions are:

Exceptional aquatic biodiversity.
1> Units (11) with mIBI scores of 24 or greater.

High aquatic biodiversity with high potential NPS pollutant loads.
2> Units (12) with mIBI scores of 18 or greater and all high ranked total NPS pollutant loads.

High public water supply protection need with high potential NPS pollutant loads.
3> Units (8) with source water concentration values greater than 30 and any high ranked total NPS pollutant load.

High public water supply protection need with NPS impaired surface water at intake.
4> Units (35) with NPS impaired waters immediately upstream of the source water intake.

Excessive agricultural loadings.
5> Units (11) with potential agricultural nutrient loads (either N or P) greater than four times the standard deviation from the mean agricultural nutrient load.
6> Units (7) with potential agricultural sediment load greater than four times the standard deviation from the mean agricultural sediment load.

NPS REDUCTION ACTIVITIES

Efforts to reduce NPS pollution in Virginia have been undertaken by government agencies - federal, state, regional, and local, as well as by citizen action. In many cases the activities are cooperatively performed and funded. Descriptions of the cooperative NPS reduction activities can be found at the NPS Management Plan website and document. Most of these efforts target particular watersheds. Among them and elaborated upon at this site are TMDL studies and Implementation Plans, Nutrient Management, Agricultural Cost Share incentive programs for BMP installations, and incentives for the set aside of agricultural land.

Total Maximum Daily Loads

TMDLs, described elsewhere in this 305(b) report, are developed for waters that have been determined to be impaired and are so listed in Virginia's EPA approved 2014 303(d) report. Streams are not listed as impaired however due to high concentrations of nitrogen, phosphorus, or sediment, but rather because they cannot support, or can only partially support, one or more of the five designated uses. This is because water quality standards do not exist for concentrations of these pollutants for free-flowing waters. Nevertheless, certain impairment causes are primarily due to nonpoint source pollutants

(see Impaired Waters in this chapter) and VADEQ staff has often determined that there are nonpoint sources for these impairments. This section of the NPS Assessment provides an analysis and presents a map characterizing TMDLs, by hydrologic unit, where NPS sources appear to be dominant.

For TMDLs currently being developed, the hydrologic unites were divided between those with and those without a predominant nonpoint source. Most of the water quality impairments in Virginia are due to nonpoint source pollution. Consequently, most of the TMDLs that are being undertaken have a nonpoint source component. These studies are focused on identifying the sources of the impairment causes, quantifying the loadings of these sources to the water, and determining the load reduction needed to meet the use criteria. The development of an Implementation Plan is expected following the completion of a TMDL study for a particular watershed. Implementation of the plan's course of action then follows.

The number of TMDL implementation projects underway or completed is continually increasing. Table 5-4a lists the NPS TMDL Study Reports (excluding estuarine, shellfish, and those developed for toxic pollutants), and Table 5-4b lists the NPS TMDL Implementations Plans as of December 31, 2016, by their status, which is a temporal condition. At that time, there were 74 completed, NPS dominated TMDL Implementation Plans covering 894 unique impaired waters. These plans represented 4,842 impaired segment miles and 1,477 impaired reservoir acres (ID305b Assessment Units, from Virginia's 2014 Integrated Report), which may be addressing more than one pollutant for a water segment. In addition, there were 223 NPS dominated TMDL studies that have been approved by the EPA covering 745 hydrologic units with impaired segments. The number of TMDL Study Reports completed cannot be directly compared to Implementation Plans completed, as the geographic area and impaired waters included may vary. Implementation Plans may be developed for only a portion of a TMDL Study or include areas from multiple adjacent studies with similar land uses, and addressed by similar reduction strategies.

Whereas, streams or water bodies are listed as impaired, it is the watershed of those impaired stream segments and water bodies that are the focus of nonpoint source pollutant reduction activities. The hydrologic units listed in Tables 5-4a and 5-4b are those in which some portion of the unit contains the listed impaired stream segment. Sometimes the entire area of the listed hydrologic unit is the watershed of the impaired stream segment, but often only a portion of that unit must be studied for a TMDL. Figure 5-17, shows the true TMDL study areas and thus gives a better indication of the geographic extent of where the work is being performed. One difficulty in geographically representing the extent of multiple TMDL areas is that they often overlap – the watershed of a TMDL for a headwaters stream becomes part of the watershed of a TMDL for a larger water feature downstream, perhaps with a different pollutant/stressor. In Figure 5-17, the latest EPA approved TMDL work is displayed by impairment type and Figure 5-18 likewise shows the true TMDL Implementation Plan areas, which also include geographic overlap.

Agricultural Cost Share Program

The Virginia Agricultural Cost Share Program (VACS) offers incentives to farmers and agricultural landowners to encourage the installation and use of a number of approved techniques (BMPs) for reducing agricultural related nonpoint source runoff. While the program aims to address nonpoint source pollutants statewide, specific hydrologic units are targeted based on the agricultural loads estimated from the NPS Assessment (see Agricultural NPS Pollution Loads) and other factors. Soil and Water Conservation Districts further target the practices to individual needs within their district within these load priority areas.

Funding support for the implementation of these practices has been borne by the state and the federal government since the program's inception in 1985. The number of installations per year has varied widely over the years, correlating with the variation of funds available to the program. At this time the primary funding source is the Virginia Natural Resources Commitment Fund, a sub-fund of the Water Quality Improvement Fund (WQIF) established by the Commonwealth's Water Quality Improvement Act (WQIA). Other state and federal funds may be used however, such as Chesapeake Bay Implementation Grants.

Table 5-5 contains a summation of the installation or practice of several of the more common NPS BMPs

initiated in the 2014 and 2015 program years of the VACS (July 2013 – June 2015). Other NPS BMPs in this period addressed the use of conservation tillage, nutrient management planning, terracing, sinkhole protection, wetland restoration and conversion, irrigation water recycling, strip cropping, and the capping of abandoned wells. Still other NPS BMPs addressed the installation of water table control structures, runoff impoundments, agricultural chemical and fertilizer handling facilities, composter facilities, water diverters, animal waste and mortality facilities, and the installation, repair, and pump-outs of septic tanks.

Additional information on agricultural best management practices and the cost-share program can be found at http://www.dcr.virginia.gov/soil_and_water/costshar.shtml. Other efforts to reduce NPS pollutants include local and state stormwater controls, BMP installations by the USDA, and silviculture BMP installations by the VDOF. These and other efforts reduce estimated initial loads as calculated in the NPS pollution loadings of this assessment.

Table 5-5 NPS BMP Installations and Metrics, Program Years 2014 & 2015 (July 1, 2013 through June 30, 2015)

Basin	Acres of Riparian & Wildlife Buffer	Miles of Fencing**	Acres of Erosion Stabilization	Acres of Grazing Land Managed	Acres of Cover Crop	Acres of Sod Filters and Waterways

Conservation Reserve Enhancement Program

The USDA's Conservation Reserve Program (CRP) provides incentives for the removal of agricultural land from production to protect environmentally sensitive land alongside rivers and streams. The Virginia Conservation Reserve Enhancement Program (CREP) augments CRP by providing for state enhanced cost-share and rental payments for conservation practices focused on the restoration of riparian buffers and wetlands. The Virginia CREP also funds the purchase of conservation easements on the restored riparian buffers.

Most, but not all areas of the state qualify for CREP assistance. Maps showing where CREP assistance is available can be found at http://www.dcr.virginia.gov/soil-and-water/crep-areas. The metrics reported in Table 5-5 include the impact of CREP practices during this period. The USDA's CRP increases the reported results. Information about CRP can be found at https://www.fsa.usda.gov/programs-and-services/conservation-programs/index.

Nutrient Management

The Virginia Nutrient Management Program which is administered by Code of Virginia §10.1-104.2 is designed to detail the most efficient use of fertilizers and manures on farms and urban lands in the Commonwealth. Plans are customized to fit a particular operation. The potential productivity of each field is considered along with an inventory of available nutrients from the soil, crop residues, manures, and commercial fertilizers. Nutrient management plans are flexible, based upon crop responses to nutrients, and focus on efficiently using those nutrients.

In Virginia, nutrient management plans are created by nutrient management specialists employed by VADCR. These specialists offer hands-on assistance with soil and tissue sampling, the use of soil surveys, equipment calibrations, and interpreting results to improve farmer efficiency. VADCR has 14 staff specialists who assist farmers, mostly of animal operations, in developing and implementing nutrient management plans.

There is also a private sector involvement in nutrient management activities. Statewide, there are currently 474 certified agricultural nutrient management plan writers, who record the majority of the acreage being managed each year. In addition, Virginia has an Urban Certification program with 174 certified urban plan writers. These plans are written for urban lands consisting of state owned lands, golf courses, businesses, and other urban areas. For the period ending in 2014 there are now over 905,000 acres statewide with a current nutrient management plan. Table 5-6 contains an accounting of the active plans in 2014.

Table 5-6 Acres Placed Under a Nutrient Management Plan As of 6/30/2014

Basin	Crop Acres	Hay Acres	Pasture Acres	Specialty Crop Acres	Turf & Landscape Acres
Albemarle Sound	23940	7		50	
Atlantic Coastal	25936			1420

** excludes the Shenandoah

Additional information on the Commonwealth's nutrient management program can be found at http://www.dcr.virginia.gov/soil_and_water/nutmgt.shtml.

Model Development and Estimation of Pollutant Loadings

The GWLF NPSA2016 model was calibrated for use in Virginia's NPS Assessment by the VT BSE prior to the 2016 assessment model runs. Since 10 years had elapsed without major changes to the modeling procedures, the modeling procedures were updated along with traditional model input data updates. The same database structure from the 2002 and 2006 calibrated models was used to evaluate a multiple-year period with output categories based on agricultural, urban, and forest land uses. Explicit 2016 version revisions to GWLF modeling, calculations, and approach include:

1. Model code corrections to the daily erosivity equations
2. A correction to the KLSCP (K – erodibility factor, LS – slope length factor, C – cover and management factor, P – support practice factor) calculation in a pre-model data processing spreadsheet (reducing sediment and attached nutrient loads by a factor of 5.8)
3. A unit conversion correction to the 'Soil Test' total P Concentration (reducing current soil P values to approximately 20% of previous ones)
4. Use of CFSR rainfall, which generates time-series at the centroid of each VAHU6 watershed
5. Updated model simulation period from 1985-2003 climate data to 1995-2014 climate data
6. Inclusion of a channel erosion component (reported as part of total load only) based on daily flow, channel depth, perennial stream length, and other hydrologic unit characteristics for which data had not previously been available
7. Improved representation of area-based parameters for hydrologic units along the state's boundary, referred to as 'fringe' watersheds, through inclusion of their out-of-state drainage areas
8. Septic loads were removed from the urban load category and are only reported in the total loads and rankings
9. Parameter algorithms or values were revised for LS-factor (topographic), manure nutrients, and C-factors (cover management), to reflect updates from the literature and from expert panel analysis for the Phase 6 Chesapeake Bay watershed model

Model input data updates for the simulation period included:

1. Land uses from information compiled from the MRLC National Land Cover Database (NLCD), USDA-NASS cropland data layer, Ag census, VADCR, VDMME, VDOF, and CTIC
2. Farm animal numbers and corresponding manure generated
3. Version 5 of the 6th level hydrologic unit system for Virginia
4. Average soil K factors (soil erodibility) (with inclusions) by updated land uses by updated hydrologic units
5. Soil Phosphorus (P) content from more recent and more resolute Virginia Tech Soil Testing Lab results
6. BMP generalized pass through factors from information provided by localities, VADCR, and NRCS

Hydrologic calibration was performed using the observed conditions at 113 monitoring sites across Virginia as assembled by the CBP Office primarily from the USGS and the VADEQ for the CBWM. Calibration watersheds were created that corresponded to these monitoring station points and were as consistent as possible with existing NWBD unit boundaries. There are portions of Virginia that are

downstream of these monitoring sites, however, that could not be calibrated in this manner. To calibrate the model for these portions of the state, the BSE defined six physiographic regions covering Virginia. Regions were comprised of aggregated 6th level NWBD units that were adjusted to coincide with the aforementioned calibration points. A limited set of parameter values were then modified by region during the calibration process of the upstream calibration watersheds until flows simulated by the GWLF model output were sufficiently similar to the observed data. Final parameter values per region were then assigned to the downstream portion of each region. The GWLF assessment runs used and produced data for the 6th level hydrologic units (1237 units) in Virginia; 11 other units that are all water and three small units added to the hydrologic unit system after model calibration were not modeled. GWLF assessment runs in 2016 used a land use / land cover data set developed by VADCR from a number of sources[6] to represent 2012 conditions. The 2012 conditions were simulated to align with dates of the latest land cover data and agricultural census (2012) data available when the 2016 NPS Assessment occurred.

Table 5-7 lists the land use classification system used in the GWLF assessment runs and the equivalent generalized model output land use classes. Spatially attributed BMP and nutrient management plan effects are measured as both land use changes[7] to the aforementioned 2012 land use/land cover data set and as fractional reductions to the loadings by modeled land use.

Table 5-7 Land Use Classification

Original Class	Derived Class	Modeled Class	NPS Assessment
Pine Forest Hardwood Forest Mixed Forest		Forest	Forest
Forest Harvest		Disturbed Forest	
Crop Bare Soil (Portion)	Conventional Tillage Conservation Tillage Hay Unimproved Pasture Pasture Cattle-Grazed Pasture Poultry Litter Manure Acres	Conventional Tillage Conservation Tillage Hay Unimproved Pasture Pasture Cattle-Grazed Pasture Poultry Litter Manure Acres	Agriculture
Pavement Rooftop		Impervious Urban	Urban
Residential/Industrial Grassland Bare Soil (Portion)		Pervious Urban	
Natural Barren Extraction		Barren	
Open Water Salt Marsh		Not Modeled	

Output from the GWLF assessment runs are in the form of average annual loads (L) of each NPS

[6] The base spatial layer for the 2012 land use / land cover data set was the 2011 NLCD. Agricultural uses were modified using the USDA 2012 Census of Agriculture and the 2012 USDA NASS, as well as tillage practice surveys by VADCR (2015) and the National Crop Residue Management Survey (2007) from the CTIC. Barren classes were modified using data from the VDMME. Disturbed forest was determined with the help of VDOF timber harvesting data. Additional classes were based on processes developed for VADCR by The Academy of Natural Sciences of Philadelphia (1997) using data from Virginia's confined animal databases.

[7] It was not necessary to change the land use to represent land use change NPS BMPs in this assessment because they were already captured in the source data.

pollutant (p: TN, TP, and TS) per modeled land use[8] per unit. From this, two forms of unit area loads were calculated – per hectare (h) of general output land use class (l: agriculture, urban, and forest) per hydrologic unit (w) load (luUAL) and per hectare of total modeled land (a) per hydrologic unit (w) load (UAL).

The luUAL value is preferable to the load values themselves when comparing the loading impacts of the individual output land use classes between hydrologic units. They are normalized in that the size of the hydrologic unit does not impact this value. This measure can isolate high loading rates of the general land use classes. It is calculated as:

$$luUAL(plw) = L(plw) / h(lw)$$

While the above calculation is useful it does not necessarily identify those hydrologic units in which NPS reduction activities should be focused[9]. Therefore, the UAL was used for ranking hydrologic units in this assessment report but significant luUAL values were used in flagging units in need of attention. The UAL per output land use class per pollutant for each hydrologic unit is calculated as follows:

$$UAL(plw) = L(plw) / h(aw)$$

The output loadings provide a statewide equivalent of the types of results that Virginia has been able to obtain from the CBWM for the Chesapeake Bay drainage area of the Commonwealth over the last twenty seven years. Table 5-2 reports the final statewide loadings by pollutant by general land use class and the amount of land in Virginia by general land use class. Loading values in this table reflect the loads after the reductions are applied from active BMPs installed over the previous sixteen years

[8] Not all possible land uses were modeled (see Table 5-7). The area of a particular unit as used in these calculations would not include the hectares of non-modeled land uses occurring in that unit.

[9] For instance, units with high loading rates for agricultural land may have only a small amount of this land use and therefore small total loads of pollutants from agricultural uses. Furthermore, any action (if possible) in any year could encompass all reasonable reduction activities, thus making this hydrologic unit less worthy of further attention.

CHAPTER 6 GROUNDWATER PROTECTION PROGRAMS/ASSESSMENT

Groundwater programs in Virginia strive to maintain existing high quality water through adopted statutes, regulations, and policies. Advancing groundwater protection efforts is the goal of many programs in numerous state agencies. The 2010 USGS Water Use report (https://pubs.usgs.gov/circ/1405/) estimated that approximately 1.65 million Virginians depend on groundwater for their domestic supply. Approximately 3 out of every 10 Virginians use groundwater from public water supplies, private wells, or springs for their daily water supply. While Virginia's groundwater is generally of good quality, both the quality and quantity can vary across the five physiographic provinces found in the state. Reliance on groundwater is also highly variable across the state, depending on a variety of geographic, geologic, and socioeconomic factors.

General groundwater quality information by physiographic province:

Cumberland Plateau
Geology: Sedimentary rock yielding groundwater of varying quality
Pollution Potential: Moderate

Valley & Ridge
Geology: Sedimentary rocks including limestone, dolomite, and shale
Pollution Potential: High in limestone areas where groundwater moves rapidly
Management Efforts: documentation and some monitoring of quantity and quality of springs, some limited ambient groundwater quality sampling

Blue Ridge
Geology: Sedimentary, igneous, and metamorphic rock; well yields are low
Pollution Potential: High, because of rapid movement of water in fractures, joints, and bedding planes
Management Efforts: documentation and some monitoring of quantity and quality of springs, some limited ambient groundwater quality sampling

Piedmont
Geology: Diverse geology with a wide range of groundwater quality and availability
Pollution Potential: Low to moderate

Coastal Plain
Geology: Unconsolidated sand, clay, marl, and shell strata; groundwater is abundant and use is high
Pollution Potential: High, due to geology and population density
Management Efforts: monitoring of water quality parameters by permittees, limited documentation and monitoring of quantity and quality of springs, some ambient groundwater quality sampling, chloride monitoring strategy

The organizational objective of DEQ's Groundwater Characterization Program (GWCP) is to protect Virginia's environment and promote the health and well-being of its citizens by collecting, evaluating, and interpreting technical information necessary to manage groundwater resources of the Commonwealth. The Commonwealth is divided into three regions to include the Coastal Plain, Piedmont-Blue Ridge, and Valley-Plateau. Each region has a staff geologist assigned to it. Staff assures that necessary information is available to support resource management decisions, water supply planning activities, groundwater availability, drought monitoring, and support the expansion or creation of groundwater management areas. Staff in this program also has responsibility for monitoring and maintaining the 225 wells in the State Observation Well Network. Staff are active participants in outreach and educational opportunities in order to increase public awareness of the wide range of issues affecting Virginia's water resources.

Initial efforts include cooperation with other state and federal agencies involved with groundwater related activities to compile historical water well construction, withdrawal, and water quality data into a GIS database as well as develop procedures to automate the acquisition of new data. Long range goals include expansion of the State Observation Network west of the fall line and publication of regional groundwater resources reports.

The following paragraphs briefly describe groundwater protection activities in the Commonwealth. Information provided in Tables 6-1, 6-2, 6-3, 6-4 and 6-5 is presented for the Commonwealth as a whole.

Regional Groundwater Reports

State Water Control Board (SWCB) geologists compiled 18 groundwater resources reports to document the availability, utilization rates, and water quality of groundwater resources within selected counties and political sub-regions of Virginia. These reports continue to be the only readily available source of information pertaining to the occurrence, movement, and availability of groundwater for a large number of the areas initially investigated. Although the majority of these historical reports are out of print, the reports are available electronically:
http://www.deq.virginia.gov/Programs/Water/WaterSupplyWaterQuantity/GroundwaterCharacterization/ReportsPublications.aspx

Current descriptions of the regional groundwater conditions in the Shenandoah Valley and Blue Ridge Geologic Province have been documented in two recently authored reports by Groundwater Characterization staff. Groundwater Resources of the Blue Ridge Province, Virginia (VDEQ OWS Technical Bulletin 12-01) and Water Use in the Shenandoah Valley, Virginia 1982-2010 (VDEQ OWS Technical Bulletin 12-02) are available electronically:
http://www.deq.virginia.gov/Programs/Water/WaterSupplyWaterQuantity/GroundwaterCharacterization/ReportsPublications.aspx.

Database Integration

DEQ's Office of Water Supply has taken significant steps since the last Integrated Report (IR) to integrate its legacy databases into a common, geo-referenced content management system. To date, water withdrawal reporting, water withdrawal permit data, private well registration and well construction data, and local water supply planning data, have been migrated to this new system. Full integration is anticipated by the end of 2018. The databases described below are relevant legacy data sets that have been migrated.

Statewide Well Construction Database

One of DEQ's goals is to merge the various sources of historical and new well information into one statewide database that can be used for regional analysis of groundwater aquifer systems. Major challenges to this goal include managing data duplication and disparities among multiple data sets and quantifying location accuracy. Efforts to sort and merge this data were completed in 2010: http://www.deq.virginia.gov/Programs/Water/WaterSupplyWaterQuantity/GroundwaterCharacterization/WellDatabase.aspx. Since 2010, the database has grown from about 35,000 wells to nearly 57,000 wells. Additional wells have originated from a number of data sources including digitized data from water well drillers, the VDH VENIS and SDWIS databases, county specific well databases, and project specific data collected and entered into the database. Despite this database being the largest of its kind in Virginia, it is representative of a fraction of the millions of wells that have been drilled throughout the State. Most wells in Virginia have been and continue to be documented by a paper well completion report, unavailable electronically. The hydrologic conditions encountered by the driller will likely never be incorporated into a georeferenced database that could be utilized to better understand local hydrogeologic conditions. For this reason, DEQ continues to encourage the development of a streamlined process for accurately reporting the location and construction details of newly completed wells in a digital format.

In 2015, the General Assembly amended the Ground Water Management Act of 1992 to require that all new private wells constructed in a Groundwater Management Area must be registered with DEQ. This requirement became effective on July 1, 2016. A number of improvements have occurred with this legislation. DEQ and VDH have worked together on a common set of well construction information to be collected from well drillers and have linked their database tools. DEQ also established an on-line well registration program that allows well drillers to enter the agreed upon information into the on-line database. In addition to these new wells in the Coastal Plain some well drillers are also entering their legacy well construction data and data for wells from outside the GWMA.

Statewide Legacy Geochemical Database

Staff compiled a master database of legacy ambient water quality data of waters from wells and springs throughout the Commonwealth in 2010. In 2014 the database was revised to describe additional geochemical and field collected parameters and to accept recently acquired ground water sampling data from ambient groundwater monitoring efforts. Ambient water quality data comprising this database includes major ion geochemistry, trace elements, nutrients, radiologicals, and field parameters. Nearly 17,000 samples taken from approximately 8,500 geo-referenced wells and springs are currently in the data set. When combined with location data, ambient water quality samples from wells and springs provide valuable information about the background concentrations of naturally occurring ionic constituents and field parameters of groundwater flow systems. In addition to their value in describing the geochemical conditions within natural groundwater flow systems it is anticipated that these data will be used by municipalities, consultants, and state and federal agencies for a wide variety of applications such as determining the extent and magnitude of elevated ionic concentrations (above background levels) due to groundwater contamination from anthropogenic sources, for predicting chemical and biological interactions due to the contamination of groundwater, and for optimizing well placement to insure high quality drinking water for private residences and municipalities.

Statewide Legacy Spring Database

Since the last IR, staff created a statewide spring database that it continues to maintain and add data. See: http://www.deq.virginia.gov/Programs/Water/WaterSupplyWaterQuantity/GroundwaterCharacterization/SpringDatabase.aspx. This database is the most comprehensive of its kind in Virginia. The database contains basic information necessary to understand regional water resources in such complex terrains as the carbonate aquifers of western Virginia. These data have value to other programs in DEQ such as Pollution Response and Petroleum Storage Tanks that deal with subsurface contaminant transport and has recently been integrated into the development of certain TMDL studies in the Shenandoah Valley. Working agreements, standardized forms and definitions have been developed by staff that have been used by field personnel in sister agencies such as DCR and DMMR in order to increase the rate of compilation of new springs into this central database containing spring locations, morphology, discharge, and basic geo-chemistry. There are currently nearly 3,000 spring visit entries (which could include quantification of spring discharge and measurement of basic water quality parameters), and 330 water quality samples for the 925 springs in the database.

State Observation Well (SOW) Program

The DEQ collects data on groundwater levels at 225 wells and the USGS collects data on groundwater levels at 142 wells in the USGS/DEQ Groundwater Level Monitoring Network. One hundred thirty one of the wells in the DEQ/USGS observation well network have been converted to real time monitoring with levels measurements stored once every 15 minutes and uploaded hourly to the USGS server using satellite telemetry technology. Data from the wells in the DEQ/USGS observation well network are published in the Annual Water Data Report: http://wdr.water.usgs.gov/. Currently, DEQ/USGS water level data are available on a USGS interactive map browser at

http://groundwaterwatch.usgs.gov/statemap.asp?sc=51&sa=VA. This network of wells provides real-time groundwater level data from multiple locations throughout the state. These data are becoming an increasingly important metric for regional water supply planning efforts and drought monitoring forecasts. The information provided by these wells is important for monitoring drought conditions, determining when groundwater recharge actually occurs, and monitoring the effects of groundwater withdrawal. Additionally, the groundwater level data collected cooperatively by DEQ and USGS contributes to the calibration of several groundwater flow models developed for management of the resource including the VAHydro-GW (coastal Plain aquifer system), VAHydro-GWES (Eastern Shore), and several small regional scale models built in the western part of the state.

Since 2010, 21 wells have been added to the state observation well network. All additions during this time have occurred in the Coastal Plain for the purpose of monitoring hydraulic heads in the multi-aquifer Coastal Plain groundwater system. In 2015, unused groundwater wells in Scott (Tennessee-Big Sandy River Basin) and Powhatan counties (James River Basin) were investigated with a borehole camera and geophysical logging system to determine their suitability for incorporation into the statewide groundwater level monitoring network. These wells have been flagged for incorporation into the state observation well network in the hard rock portions of Virginia and will be brought into the network as time and resources permit.

Geochemical Sampling Program Development

In 2013, staff developed an ambient groundwater quality monitoring strategy document to serve as a plan for characterizing groundwater geochemical conditions throughout the Commonwealth. The document describes the extent of currently available groundwater chemistry data, provides a rationale and methodology for a scientifically defensible distribution of sampling resources, and provides a cost analysis for the full implementation of the sampling strategy. Additionally, an annual implementation plan was developed detailing the portions of the sampling strategy in each geologic terrain that will be accomplished with respect to that fiscal year's budgetary considerations. The Virginia Ambient Groundwater Monitoring Strategy and the FY14 Ambient Groundwater Quality Monitoring Implementation Plan were finalized in November of 2013 after review and input from a variety of federal, state and private organizations and institutions. The strategy and FY2014 implementation plans can be viewed at http://www.deq.virginia.gov/Programs/Water/WaterSupplyWaterQuantity/GroundwaterCharacterization/ReportsPublications.aspx.

Development of the strategy included testing and modification of sampling equipment and methodology in order to attain the highest sampling quality control possible in the range of geologic, hydrologic, and well construction conditions encountered throughout the state. Groundwater samples were obtained at selected wells and springs in Virginia during the 2013 calendar year and continue to be collected in accordance with the finalized 2014 implementation plan. A fiscal year implementation plan is available annually that details sampling activities for the period. In 2018, a compilation and analysis of groundwater sampling performed by staff in calendar years 2013 - 2016 will be made available to the public. This staff member is funded through the use of EPA section 106 funding.

EPA/DEQ/USGS Cooperative Studies

DEQ continues to cooperate with the USGS on a continuous effort to update and revise the hydrogeologic framework to better manage the groundwater resources of the Virginia Coastal Plain. Since the last IR, two significant hydrogeology studies have been completed and published. The first effort characterizes the hydrology and heterogeneous morphology of the Potomac aquifer sediments. The study concludes the regional behavior of these sediments as one aquifer rather than as three distinct sub-units. A USGS publication entitled, "Sediment Distribution and Hydrologic Conditions of the Potomac Aquifer in Virginia and Parts of Maryland and North Carolina" was published in 2013. https://pubs.usgs.gov/sir/2013/5116/. A second effort characterizes the hydrogeology of the Piney Point aquifer was initiated in 2013 to facilitate sound management of the Virginia Coastal Plain groundwater resource. Improved information on the Piney Point aquifer in the Virginia Coastal Plain is needed to

effectively plan for a sustainable water supply. Wells in the Piney Point aquifer in rural areas widely yield from 10 to 50 gallons per minute, whereas larger residential and municipal wells in developed urban and suburban areas yield as much as 400 gallons per minute. Two State Observation Wells and a core hole were completed in York County in 2015 to provide detailed hydrogeologic information on the productive limestone part of the Piney Point aquifer, and to help in assessing its geographic and hydrologic limitations as a water supply. A USGS publication entitled, "Hydrogeologic Framework and Hydrologic Conditions of the Piney Point Aquifer in Virginia" was published in 2017. https://pubs.er.usgs.gov/publication/sir20175041.

A third significant effort is a follow-up to the 2010 USGS publication "Groundwater-Quality Data and Regional Trends in the Virginia Coastal Plain, 1906–2007." A USGS publication entitled, "A conceptual framework and monitoring strategy for movement of saltwater in the coastal plain aquifer system of Virginia" was published in 2015. https://pubs.er.usgs.gov/publication/sir20155117 . This study provided a comprehensive review of chloride data in order to develop a conceptual monitoring strategy for tracking the movement of saltwater in the Coastal Plain aquifer system. The analysis is based on spatial relations between the saltwater-transition zone and 612 groundwater-production wells that were regulated during 2013 by DEQ. The vertical position and lateral distance and direction of the bottom of each production well's screened interval was calculated relative to previously published groundwater chloride iso-concentration surfaces. Spatial analysis identified 81 production wells completed in the Yorktown-Eastover and Potomac aquifers that are positioned in closest proximity to the 250-milligrams-per-liter chloride surface, and from which chloride concentrations are most likely to increase above the U.S. Environmental Protection Agency's 250-milligrams-per-liter secondary maximum-contaminant level. Monitoring potential withdrawal-induced movement of saltwater in the Virginia Coastal Plain aquifer system is needed to detect increases in chloride concentration before groundwater-production wells become contaminated.

All of the above studies were funded through the use of EPA section 106 funding.

Groundwater Withdrawal Permitting Program

The Virginia General Assembly enacted the Ground Water Act of 1992 (Act) and repealed the Ground Water Act of 1973. The Act establishes criteria for the creation of groundwater management areas and requires entities that withdraw more than 300,000 gallons of groundwater in any month to obtain a permit. Between 2009-2013, growing concerns over the impacts of increased water use by new or expanding withdrawals, overlapping cones of depression, and declining water levels in the Coastal Plain aquifers compelled the Board to consider expanding the Eastern Virginia GWMA to include all of the Coastal Plain east of I-95 in order to ensure comprehensive management of the aquifer system. Modifications to the Groundwater Withdrawal Regulations accompanied the expansion, effective January 1, 2014, codified the criteria for the declaration of GWMAs and for the issuance of groundwater withdrawal permits to withdrawers of groundwater in excess of 300,000 gallons per month in a declared GWMA. Over 100 existing user permit applications were received during 2014 as a result of the Eastern Virginia GWMA expansion. Through 2016, 53 Existing User Groundwater Permits were issued. Of those 82 facilities, 34 elected to prepare and submit a Water Conservation and Management Plan, which exceeds the current requirements of the permitting process.

In addition to the expansion of the EVGWMA, the Virginia Coastal Plain Groundwater Initiative was developed in 2014, in response to ongoing and long-term decline of groundwater levels, head loss, and growing concerns about associated land subsidence and salt water intrusion in the Coastal Plain aquifer system. In order to achieve the goal of protecting the aquifer system and providing for current and future water needs for the Commonwealth, DEQ began negotiating with the largest 14 groundwater users about potential reductions in water withdrawals, which, if implemented could begin stabilizing the groundwater level declines in the aquifer. Combined, these users represent approximately 87% of all groundwater withdrawals within the GWMA. The Initiative has resulted in 12 permits issued and 2 draft permits being developed and put on public notice. The combined result of these negotiated permits is a 52% reduction in Potomac Aquifer withdrawals and allocations. This represents a reduction in total permitted volume

allocated from the Potomac Aquifer nearly 70 MGD. DEQ continues to work on issuing concluding the issuance process for the final 2 facilities.

In 2015, the Virginia General Assembly enacted a bill creating the Eastern Virginia Groundwater Management Advisory Committee. This committee was charged with advising DEQ, the Governor, and the General Assembly on steps that could be taken to maintain the long term availability and productivity of the Coastal Plain aquifer system. The Committee's report will be submitted in November 2017.

Storage Tank Compliance Program

The Registration Program tracks ownership and technical information for some 80,000 active and closed Underground Storage Tanks (USTs) and some 16,000 active and closed Aboveground Storage Tanks (ASTs) in the Commonwealth. As of 2016 there are some 5,900 active UST facilities and some 4,000 active AST facilities in the state. Each year the program receives over 2,000 registrations that report new tanks, tank closures, and amendments to existing tank information, such as changes of ownership. DEQ and the public use the registration information to determine the identity of persons responsible for pollution prevention measures and cleanup of releases.

The AST Compliance Program regulates AST facilities of 25,000 gallons or greater that store oil. Nearly 1.4 billion gallons of oil are stored in the active regulated AST facilities across the Commonwealth. Through facility inspections, the program seeks to ensure that Virginia's AST facilities have measures in place to prevent releases and to respond quickly and effectively if releases occur.

The UST Compliance Program regulates USTs larger than 110 gallons that contain regulated substances, which include most petroleum products. Over 169 million gallons of regulated substances are stored in the 18,000 active USTs across the Commonwealth. Through tank inspections, the program seeks to ensure that USTs in the Commonwealth have measures in place to prevent releases and to have immediate notice of actual releases.

On August 8, 2005, President Bush signed H.R. 6, the Domenici-Barton Energy Policy Act of 2005. In Title 15 of the Act are amendments to Subtitle I of the Solid Waste Disposal Act addressing the regulation of underground storage tanks (primarily petroleum). Based upon EPA guidelines, DEQ revised its regulations on September 15, 2010 to incorporate UST secondary containment, delivery prohibition and operator training requirements. In 2015 EPA updated the federal UST regulation and DEQ is currently updating the DEQ regulation 9VAC25-580 accordingly to be effective in late 2017.

The existing State Water Control Law (§62.1-44.34:9(2) & (8)) requires DEQ to carry out its powers and duties with regard to underground storage tanks in accordance with applicable federal laws and regulations.

Storage Tank Remediation Program

The Remediation Program directs the investigation and cleanup of petroleum-contaminated sites managed by responsible parties. The DEQ ensures that appropriate emergency response, initial abatement measures, site investigation and site remediation are performed by the responsible party. The DEQ also authorizes activities eligible for reimbursement from the Virginia Petroleum Storage Tank Fund.

The DEQ will conduct investigation and cleanup of high-priority petroleum contaminated sites in instances where the responsible party is unknown or financially unable to undertake the required work. Through a number of contractors, the DEQ conducts emergency response, initial abatement measures, site investigation and site remediation.

The DEQ also provides immediate, interim, and permanent relief to individuals whose drinking water wells have been rendered unusable by petroleum contamination. Through a DEQ contractor, carbon filtration units (CFUs) are installed and maintained on contaminated wells until a permanent solution is

implemented. Permanent solutions typically include extension of an existing public water supply or installation of a new well free from petroleum contamination.

More than 9,200 site cleanups were completed from January 2009 through December 2014. Average cleanup time and average cleanup costs per site are among the lowest in the nation. From the inception of the program through December 2014 DEQ has overseen over 35,000 cleanups.

Office of Financial Responsibility and Waste Programs

The DEQ's Office of Financial Responsibility and Waste Programs implements the requirements for groundwater monitoring and corrective action as originally defined under Subtitle D of the Resource Conservation and Recovery Act (RCRA). Funding for the program comes from the Commonwealth's General Revenue augmented by permit fees. All groundwater data are collected by the solid waste facilities and their consultants and reviewed by DEQ staff for adherence to regulatory requirements under 9 VSWMR 20-81-250 and 260.

Information provided in Table 6-4 Solid Waste Landfill Corrective Action category was derived for the sites in Virginia's Solid Waste Corrective Action universe, as reported through December 2016. More than 100 sites have been identified as having the potential for impacts on human health and the environment by exceeding one or more of their groundwater protection standards. In cases where groundwater monitoring detects exceedences above groundwater protection standards (such as EPA's Maximum Contaminant Levels for drinking water), facilities are required to implement clean-up measures under a process called groundwater Corrective Action. As shown in Table 6-4, the number of sites which have implemented groundwater Corrective Action across the Commonwealth is 59. To date, two landfill sites have met their groundwater clean-up goals and have been allowed to terminate corrective action.

Office of Remediation Programs

Included in Table 6-4 are groundwater contamination statistics from the DEQ's Office of Remediation Programs (ORP). ORP consists of the Federal Facilities Restoration Program, Superfund Program, Voluntary Remediation Program, Site Assessment Program, and the Brownfields Program. The Federal Facilities Restoration (FFR) Program includes 44 Army, Navy, Marine Corps, Air Force, Defense Logistics Agency, Federal Aviation Administration, and NASA installations and 12 Formerly Used Defense Sites (FUDs). Currently 12 Federal Facilities and 1 FUDs site are listed on the National Priority List (NPL). The mission is to clean up contaminated sites at military installations through a partnering team process. The Department of Defense, NASA, and the EPA support the program. To date, three Federal Facilities have achieved the basewide construction completion milestone – all remedies are in place and functioning as intended. The Superfund Program, funded with both Federal and State dollars, carries out investigation and cleanup activities required by law or legal agreements at 23 NPL sites. Four of these sites have now been cleaned up and delisted. The Voluntary Remediation Program (VRP) provides a mechanism for eligible participants to voluntarily clean up properties not mandated for remediation under existing environmental laws. This program serves as a mechanism for cleanup of brownfields sites. There are over 122 sites undergoing active remediation and over 312 sites which have completed cleanup and reached closure. A combination of program enrollment fees (user fees) and EPA grant funding supports the Voluntary Remediation Program. The Site Assessment Program (SAP), supported by EPA, is designed to assess potential CERCLA sites for inclusion on the NPL. The DEQ's Brownfields Program, also supported by a combination of state funds and EPA grant funding, provides incentives to owners and/or developers of potential brownfield sites to promote the redevelopment and reuse of these underutilized properties. The Brownfields program has assisted with the redevelopment and reuse of over 120 sites in Virginia in the last three years. None of these five programs currently collect groundwater quality data; however, they do receive and review data collected by outside sources.

Hazardous Waste Groundwater Activities

Throughout the reporting period from Jan 1, 2009 – Dec 31, 2014, the DEQ implemented the requirements for groundwater monitoring and corrective action as specified by the Resource Conservation and Recovery Act (RCRA). Funding for the program activities comes from an EPA grant covering hazardous waste management activities such as permitting, closure and corrective action, as well as compliance and enforcement. The grant does not cover data collection, with the exception of quality control samples. All groundwater data are collected by the hazardous waste facilities and their consultants, and are reviewed by DEQ staff for adherence to regulatory requirements.

Under RCRA, groundwater quality is evaluated at both permitted and un-permitted facilities that have land-based units for the treatment, storage and disposal of hazardous waste. Permitted sites have to meet strict operational requirements to eliminate or minimize the risk of impacts on human health and the environment. Permits include contingency requirements mandating clean-up in case of a release of hazardous waste from a regulated unit or as identified during the site-wide RCRA Corrective Action process. Un-permitted sites are sites where operation has ceased and the facility is in the process of removing and/or decontaminating contaminated media (closure), sites where a permit is about to be issued, or sites where RCRA Corrective Action is being undertaken under an Order or agreement with EPA or DEQ. The information in the RCRA Corrective Action category in Table 6-4 has been combined into one reporting metric including both permitted and un-permitted sites.

Information provided in the Table 6-4 RCRA Corrective Action category was derived for all the sites in Virginia's 2020 Corrective Action universe, as identified by EPA. These sites, currently numbering 121, have been previously identified as exhibiting or having the potential for impacts on human health and the environment. The number of future additions to the Corrective Action universe is expected to be small.

Most facilities have more than one waste management unit, and all units need to be evaluated for potential impacts and undergo remediation if necessary. All sites are currently in various stages of evaluation, site clean-up, or have met performance standards. To date, groundwater impacts were identified at 55 sites. For an additional 64 sites, it was determined that groundwater has not been impacted or performance standards have been met through the cleanup process. For the remaining 2 sites, additional investigation will be required.

At the 55 sites where groundwater monitoring has detected exceedances above applicable groundwater protection standards (such as EPA's Maximum Contaminant Levels for drinking water), facilities are required to implement clean-up measures. Corrective action plans for interim and/or final measures to remediate impacted groundwater have been developed for 48 sites. More detailed information for each site as well as an interactive map of Virginia facilities in the RCRA Corrective Action program can be found on DEQ's web site at http://deq.virginia.gov/Programs/LandProtectionRevitalization/RemediationProgram/RCRACorrectiveAction.aspx or on EPA's Corrective Action page at https://www.epa.gov/hwcorrectiveactionsites/corrective-action-programs-around-nation.

Source Water and Wellhead Protection Efforts

The Commonwealth and its localities work together to manage and protect water resources to meet long-term human and environmental needs. Protecting the quality of drinking water sources by preventing and reducing contamination is one of the best approaches to ensuring drinking water supply sustainability. The Virginia Department of Environmental Quality (DEQ) and the Virginia Department of Health-Office of Drinking Water (VDH-ODW) have a long history of cooperating on programs to develop and implement source water protection in the Commonwealth. In 2013, VDH-ODW worked with a firm to create a customized reporting tool into ArcGIS which organizes and manages source water data, which allows effective collaboration with waterworks to improve Source Water Assessment data. To further the agencies goal of source water protection, a number of programs are available to assist in these

efforts. The Source Water Protection Plan Development and Implementation Assistance is available for community waterworks that serve less than 50,000 people and process water directly from a drinking water supply source. DEQ is a partner with VDH-ODW in procuring contractors to develop these plans. VDH-ODW offers direct technical assistance to waterworks not already working with one of the source water protection contractors in the form of GIS maps and reports, source water protection plan templates, and other resources. Since 2005, VDH-ODW has been collaborating with DEQ to offer Wellhead Protection Implementation Project Grants for local wellhead protection implementation projects. This funding is available to localities or service authorities who own or operate a community waterworks, process drinking water directly from a groundwater supply source, have a protection strategy in place, and have an active source water protection committee. Additional information can be found at http://www.vdh.virginia.gov/drinking-water/source-water-programs/.

Table 6-1 Public Water Supply Systems and Population Served from Virginia's Source Water Assessment and Protection Reporting (June 1, 2017)

Total Number of Public Water Supply (PWS) systems	2,757
Total Number of GW-Dependent PWS Systems	2,432
Total Number of Community Water Supply Systems	1,119
Total Number of GW-Dependent Community Water Supply Systems	805
Total Population Relying on Community Water Supply Systems	6,970,183
Total Population Relying on GW-Dependent Community Water Supply Systems	496,411
Total Number of GW-Dependent Non-Transient Non-Community PWS Systems	514
Total Number of GW-Dependent Transient Non-Community PWS Systems	1,113

Pesticide Collection Program

Virginia's Pesticide Collection Program assists agricultural producers, licensed pesticide dealers, pest control firms, golf courses and homeowners with the proper disposal of unwanted pesticides. The program is an effort by the Virginia Department of Agriculture and Consumer Services (VDACS), with participation from Virginia Cooperative Extension and the Division of Consolidated Laboratory Services.

Since its inception, Virginia's Pesticide Collection Program has collected and destroyed more than one million pounds of pesticides. To administer the Pesticide Collection Program, Virginia is divided into five regions. Each year, a pesticide collection program is conducted in a different region. Once all five regions have been served, the program will start another cycle. The Pesticide Collection Program requires participants to transport their unwanted agricultural and commercial pesticides to a central collection site where the hazardous waste disposal contractor will package the pesticides for eventual disposal. If a participant cannot safely transport unwanted pesticides, the program may make arrangements to containerize the pesticides for transport. Available at no cost to eligible participants, the program is supported by pesticide fees collected by VDACS. No general fund tax dollars are used to implement the program. VDACS is unable to provide funding for the Pesticide Collection Program in 2017 therefore this program has been suspended for one year. Additional information may be found at http://www.vdacs.virginia.gov/pesticide-collection.shtml.

Plastic Pesticide Container Recycling Program

Virginia's Plastic Pesticide Container Recycling Program is a free service that provides a convenient and environmentally friendly way to dispose of properly rinsed plastic pesticide containers. The program

is a cooperative effort among the Virginia Department of Agriculture and Consumer Services, Virginia Cooperative Extension and local governments. The program is administered under national guidelines developed by the Ag Container Recycling Council. Since its inception in 1993, this program has recycled close to 1.5 million pounds of plastic pesticide containers. Containers are granulated by a contractor with assistance from VDACS and local personnel. Granulated chips are transported to recycling facilities and fabricated into items such as pallets, fence posts, field drain tiles and parking stops.

The Plastic Pesticide Container Recycling Program addresses a challenge for agricultural producers and custom applicators. Typically, pesticide applicators dispose of their empty, clean plastic pesticide containers by hauling them to the local sanitary landfill. Recycling is an environmentally responsible alternative for the disposal of properly rinsed plastic pesticide containers. Granulated chips are transported to recycling facilities and fabricated into items such as pallets, fence posts, field drain tiles and parking stops thus keeping them out of landfills and reducing the potential for contamination from improperly rinsed containers which have either been landfilled or disposed of improperly.

To participate in the Program, a locality must make application to VDACS and agree to collect, inspect and store the properly rinsed containers until granulation. VDACS provides per locality reimbursement costs annually to participating localities to offset the cost of the program. This program is funded through OPS program fees. Additional information may be found at http://www.vdacs.virginia.gov/pesticide-container-recycling.shtml.

Groundwater Protection Programs - Conclusion

Groundwater programs in Virginia strive to maintain the existing high water quality. Groundwater protection activities in the Commonwealth are as varied as the funding sources that support them. The following tables provide additional information.

Table 6- 2 Primary Sources of Groundwater Contamination

Contaminant Source	Ten Highest-Priority Sources(√)	Factors Considered in Selecting a Contaminant Source	Contaminants
Agricultural Activities			
Agricultural chemical facilities			
Animal feedlots			
Drainage wells			
Fertilizer applications	√	State GW Protection Strategy	(E)
Irrigation practices			
Pesticide applications	√	State GW Protection Strategy	(A,B)
Storage and Treatment Activities			
Land application	√	State GW Protection Strategy	(E)

Source Type Abbreviations

NPL - National Priority List (DEQ staff: K.Doran)

CERCLIS (non-NPL) - Comprehensive Environmental Response, Compensation, & Liability Information System (DEQ staff: D.Harris)

Voluntary Remediation (DEQ staff: M. Anderson)

Federal Facilities (DEQ staff: K.Doran)

UST & AST- Underground Storage Tanks & Above ground Storage Tanks (DEQ staff: B.Lamp)

RCRA - Resource Conservation & Recovery Act (DEQ staff: B. Fisher)

Solid Waste Landfills (DEQ staff: L. Beckwith)

Contaminant Type

(A) listed and characteristic hazardous waste

(B) metals, halogenated organics, POL, PCB, Pesticides

Table 6-5 Aquifer Monitoring Data

Hydrogeologic Setting [1] Commonwealth of Virginia

Spatial Description (optional) [2] NA

Map Available (optional) [3] NA

Data Reporting Period [4] January 1, 2009 - December 31, 2014

Monitoring Data Type	Total No. of Wells Used in the Assessment [5]	Parameter Groups	Number of Wells								
			No detection of parameters above MDLs or background levels		Nitrate concentrations range from background levels to less than or equal to 5 mg/l No detection of parameters other than nitrate above MDLs or background levels and/or located in areas that are sensitive or vulnerable		Nitrate ranges from greater than 5 to less than or equal to 10 mg/l Other parameters are detected at concentrations exceeding the MDL but are less than or equal to the MCLs [10]	Parameters are detected at concentrations exceeding the MCLs [11]	Number of wells removed from service [12]	Number of wells requiring special treatment [13]	Background parameters exceed MCLs [14]
			ND [6]	Number of wells in sensitive or vulnerable areas (optional) [7]	Nitrate ≤5mg/l VOC, SOC, and other parameters not detected [8]	Number of wells in sensitive or vulnerable areas (optional) [9]					
Finished Water Quality Data from Public Water Supply Wells	3,473	VOC	7,178								
		SOC [15]	3,754								
		NO_3	8,742		669						
		Other [16]									

These numbers are provided by the Virginia Department of Health, Office of Drinking Water (J.Vivas). Data is given for wells associated with mixed systems (surface and groundwater) and groundwater based systems. SOC data is limited due to waiver programs and no detections in systems that were monitored. VOC and SOC data may be incomplete due to optional data entry requirements in VDH field offices. MCL exceedence information required additional work that VDH staff limitations prevented. Software modernization efforts underway at EPA may make providing this information in future reports an easier task.

Column 5: Total number of wells (3,473) is a subset of sample results for VOC, SOC, and NO. There may be multiple sample results for a single well.
Column 6: No detections for NO3 analysis (8,742) is a combined total of sample results for contaminants 1038 and 1040.

CHAPTER 7 WATER QUALITY PROGRAMS

"The objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's waters by preventing point and nonpoint pollution sources, providing assistance to publicly owned treatment works for the improvement of wastewater treatment, and maintaining the integrity of wetlands."–US EPA

This chapter provides an overview of DEQ's on-going commitment to the protection of water quality.

CHAPTER 7.1 WATER POLLUTION CONTROL

Virginia Pollutant Discharge Elimination System (VPDES)

The Commonwealth of Virginia has operated a successful state discharge permit program since 1946. The Federal Water Pollution Control Act (the Clean Water Act) was amended in 1972 to require a uniform permit program nationwide, allowing all states to uniformly control industrial and municipal wastewater discharges. Some states elected to have the federal government manage their permit program. Virginia requested delegation of authority from EPA to administer its own permit program in conformance with NPDES regulations. In April 1975, Virginia received the authority to administer the NPDES program as the VPDES permit program. The VPDES Permit Regulation, 9 VAC 25-31, establishes the procedures and requirements for this Program.

VPDES permits establish limits on the quantity and/or concentration of pollutants allowed in the discharge. The VPDES permits implement the applicable requirements of federal effluent guidelines, as well as the Virginia Water Quality Standards. Effluent limits are written to ensure that the most appropriate of these regulations is applied to the discharge. The permittee must monitor the quality of the effluent and report the results to DEQ. The permit also requires the facility to be properly operated and maintained.

Permits may also contain additional requirements detailed as "Special Conditions" in the permit. Examples of these special conditions are:

1. Pretreatment programs for publicly owned treatment works (POTW's) – requirements for the POTW to have the ability to control the discharges from contributing industries.

2. Stormwater pollution prevention plans.

3. Toxics Management Program – this program requires the permittee to perform aquatic toxicity testing on the discharged effluent to determine reasonable potential for toxicity.

4. Land Application of Sewage Sludge.

DEQ is also utilizing the concept of general permits to streamline the permitting process and conserve resources of both the permittee and DEQ.

<u>Individual Permits</u>

- *Municipal Facilities*

There are 574 Municipal discharges currently permitted in Virginia. The term municipal generally refers to facilities that treat predominantly domestic sewage and such facilities may be either publicly or privately owned. There are 475 "minor" municipal dischargers ranging in size from > 1,000 gallons per day and < 1 million gallons per day (mgd), and there are 99 "major" municipal discharges, ranging in size

from one to 75 mgd and treating about 95 percent of all the sewage in Virginia.

- Industrial Facilities

There are 300 industrial dischargers currently permitted in Virginia. The industrial category of discharge generally refers to the discharge of wastewaters generated by industrial activities such as factories, power plants, and other industrial activities. Of these, 40 are major facilities. Industrial facilities are assigned major and minor status through an agreement between EPA and DEQ.

General Permits

General permits are written for a general class of discharge with similar effluent characteristics. Virginia was granted general permit authority from EPA in May 1991. General permits have streamlined the VPDES permit process, and reduced the paperwork, time and expense of obtaining a permit and allow staff resources to be concentrated on individual permits. General permits are promulgated as regulations and usually require application for coverage through the submittal of a Registration Statement. The following DEQ-administered VPDES general permits are available in Virginia:

- Petroleum Contaminated Sites, Groundwater Remediation, and Hydrostatic Tests (VAG83)
- Stormwater Discharges Associated With Industrial Activity (VAR05)
- Non-Metallic Mineral Mining (VAG84)
- Domestic Sewage Discharges <= 1,000 GPD (VAG40)
- Noncontact Cooling Water Discharges (VAG25)
- Seafood Processing Facilities (VAG52)
- Vehicle Wash and Laundry Facilities (VAG75)
- Concrete Product Facilities (VAG11)
- Watershed Permit for Total Nitrogen and Total Phosphorus Discharges and Nutrient Trading in the Chesapeake Bay Watershed (VAN00)
- Pesticide Discharges (VAG87)
- Potable Water Treatment Plants (VAG64)
- Stormwater Discharges From Small Municipal Separate Storm Sewer Systems (MS4s) (VAR040)
- Stormwater Discharges From Construction Activities (VAR10)

The DEQ also administers Virginia Pollution Abatement (VPA) general permits for Concentrated Animal Feeding Operations and Poultry Waste Management.

There are more than 4898 dischargers in Virginia registered for coverage under the general permits (GPs) mentioned above, not including the Pesticide GP and the Construction GP. There are 2,764 active Construction GPs. The majority of the construction GP coverage is administered by localities under the Virginia Stormwater Management Program. Additionally, the Pesticide Discharges general permit does not require a discharger to register in order to be covered under the permit. Any operator that applies pesticides under one of the five pesticide use patterns (Mosquito and Other Flying Insect Pest Control; Weed and Algae Pest Control; Animal Pest Control; Forest Canopy Pest Control. and Intrusive Vegetation Pest Control) in, over or near surface waters in Virginia is automatically covered under the general permit.

Fees for Permits and Certificates

The 1992 General Assembly enacted Section 62.1-44.15:6 of Article 2.1 of the Code of Virginia, which established a fee assessment and collection system for permits and certificates. In response to this action, the SWCB adopted a water permit fee regulation, 9 VAC 25-20, which established fee schedules for permits and certificates. The assessment of fees allows DEQ to recover a portion of the cost of processing applications for permits or certificates which DEQ has the authority to issue. In 2002 the General Assembly amended and reenacted Section 62.1-44.15:6 of the Code of Virginia. These amendments increased the existing permit fees, and were intended to make the water permit program

"self-funding". The water permit fee regulation was modified to incorporate the amendments to the law, and the modification became effective on July 1, 2002. In 2004, the General Assembly again amended and reenacted Section 62.1-44.15:6 of the Code of Virginia, and made the increased fees permanent. The water permit fee regulation was modified again to incorporate the new amendments, and the changes became effective on July 1, 2004. The major change to the law and regulation was for VPDES and VPA individual permits. The reapplication fee was eliminated for these permits and replaced with an Annual Permit Maintenance Fee, which is to be paid by October 1st of each year. In 2010 the State Water Control Board adopted amendments to the Permit Maintenance Fees section of the Fee Regulation to address budget changes made by the 2010 General Assembly. The new permit maintenance fee schedule was effective August 18, 2010 and allows for an annual adjustment of the permit maintenance fees based on changes to the Consumer Price Index.

Fees have been established for VPDES, Virginia Pollution Abatement (VPA), Virginia Water Protection (VWP), Corrective Action Plan (CAP), Surface and Ground Water Withdrawals, and General Permits. Agricultural operations are exempt from payment of permit fees. Fees for VPDES permits range from $500 for a general permit to $24,000 for a VPDES “Industrial Major” permit. There are also fees for modifications and waivers.

Fees for VPDES permits for MS4s (both individual and general permits) and for registration under the VSMP Construction GP are found in the VSMP Regulation, 9 VAC 25-870.

Toxics Management Program

Requirements for toxics monitoring are written into VPDES permits as special conditions. These monitoring requirements are developed by the DEQ Toxics Management Program (TMP), which originated in the early 1980’s. The aim of the program is to involve all industrial and municipal VPDES permit holders that potentially discharge toxic pollutants into a systematic program of biological testing. This testing is designed to identify wastewater discharges that are toxic to aquatic life.

The need for a TMP is determined at the time of permit issuance, reissuance, or modification, using information provided by the permittee as part of the VPDES permit application, as well as additional data generated by the DEQ or other sources. Generally TMP special conditions include quarterly acute, or acute and chronic toxicity testing using vertebrate and invertebrate species. The duration of testing may be based on a time period with a regular frequency (e.g., quarterly testing for one year), an event prior to discharge, or until a certain number of tests have been performed. Once the TMP data have been generated for a particular outfall, they are evaluated for reasonable potential for toxicity. If the data do not show reasonable potential, the permittee may continue biological testing at a much-reduced frequency. However, if the data show reasonable potential, a Whole Effluent Toxicity (WET) limit is developed and put into the permit with a compliance schedule.

Pretreatment Program

Virginia’s Industrial Pretreatment Program controls industrial discharges to Publicly Owned Treatment Works (POTWs). These municipal sewage treatment plants are usually not designed to treat toxic industrial wastes. Such wastes may interfere with the plant’s biological treatment processes, pass through untreated into receiving waters or contaminate POTW sludge to the extent that lawful disposal is precluded. POTWs with industrial contributors should develop a Pretreatment Program and become the Control Authority. EPA delegated oversight and regulation of the POTW pretreatment programs to the DEQ on April 14, 1989.

These municipal sewage treatment plants are usually not designed to treat toxic industrial wastes. Such wastes may interfere with the plant’s biological treatment processes, pass through untreated into receiving waters or contaminate POTW sludge to the extent that lawful disposal is precluded. POTWs with industrial contributors should develop a Pretreatment Program and become the Control Authority. EPA delegated oversight and regulation of the POTW pretreatment programs to the DEQ on April 14,

1989.

Standards imposed on industrial users include general standards, prohibitive discharge standards, categorical standards, and local limits developed by POTWs. General standards are narrative prohibitions against pass-through and interference and are applicable to all industrial users. Prohibitive discharge standards are also applicable to all industrial users and include limitations on parameters such as pH and temperature, measured in industrial discharges. Categorical standards are federal technology-based standards developed for certain categories of industries discharging to POTWs. In addition, POTWs are required to develop local limits for substances that have the potential to cause interference with treatment or pass through in toxic amounts to receiving waters.

Pretreatment facilities are controlled through municipal ordinances and are required to self-monitor and report biennially to the municipality which reports to DEQ.

The Virginia Compliance Auditing System

The DEQ monitors the performance of municipal and industrial dischargers through a computerized compliance auditing system. Under the VPDES permit program, major facilities are required to submit monthly plant performance reports based upon self-monitoring of the parameters listed in the discharge permit. Minor facilities report on an individually assigned frequency. These discharge-monitoring reports (DMRs) indicate the quality of plant effluent and whether any bypasses have occurred. Data from DMRs are entered by the regional offices into DEQ's Comprehensive Environmental Data System (CEDS), which compares all parameters to permit limits or other permit conditions, or other orders to detect any violations.

When a permit or other enforceable violation is observed through CEDS, the system assesses weighting points according to the severity and frequency of the violation(s). In addition to the automatic detection of effluent violations through CEDS, compliance schedules, as well as other required due dates both in permits and enforcement actions, are also tracked through CEDS. Weighting points are also assigned for single event violations reported to DEQ by permittees, the public or other sources. All weighting point values are assessed and tallied for the previous six reporting periods. When accumulated values exceed specified limits, or any time a violation is observed which is determined to cause environmental harm, enforcement action may be initiated. Additional enforcement activity may result from problems discovered during on-site inspections.

The accumulated records of weighting point values are used as a tool to aid objective focus when determining appropriate enforcement activity. The program also ensures that permittees are fully aware of problems as they develop and have an opportunity to improve treatment in order to maintain compliance.

Virginia Pollution Abatement Permits

A Virginia Pollution Abatement (VPA) Permit may be issued by the DEQ whenever an owner handles wastes or wastewater in a manner that does not involve discharging to a sewage treatment facility or to state waters pursuant to a valid VPDES permit. The Virginia Pollution Abatement Permit Regulation (9 VAC 25-32) was adopted in 1996. Pollution abatement facilities approved through the VPA permit program may include pits, ponds, and lagoons for waste storage, treatment, or recycling. Permits are also required for on-site facilities, such as land treatment systems. The basis for approval for such systems includes assurance that waste or wastewater will not discharge directly into state surface waters except under prescribed extreme rainfall conditions, and for protection of ground water quality.

To address and gauge compliance with the state’s groundwater standards, whenever pits, ponds, lagoons, and/or land treatment is part of a proposed or VPA-permitted facility, a ground water monitoring program may be required as part of, or prior to, receiving approval for a VPA permit. Land application is a no-discharge alternative to conventional discharging systems. Land treatment is frequently a cost-effective alternative to direct discharge to surface waters, and can be a technically sound means of waste

or wastewater utilization.

Concentrated Confined Animal Feeding Operations

The DEQ animal waste program regulates farms under both the Virginia Pollution Abatement (VPA) Permit Regulation (9VAC25-32) and the Virginia Pollutant Discharge Elimination System (VPDES) Permit Regulation (9VAC25-31). An animal feeding operation (AFO) is a lot or facility where animals are stabled or confined for a total of 45 days or more in any 12-month period, and where crops or vegetative growth is not maintained in the normal growing season over the lot or facility. AFOs that confine more than 300 animal units of livestock and handle liquid manure are required to obtain coverage under either a VPA general or individual permit. The VPA Regulation and General Permit for AFOs and Animal Waste Management governs the management of animal waste by the farm and by those who receive the manure from the permitted farm. Poultry operations that confine more than 20,000 chickens or 11,000 turkeys must register for coverage under the VPA General Permit for Poultry Waste Management. The VPA Regulation and General Permit for Poultry Waste Management governs the management of poultry waste at confined poultry feeding operations and poultry waste utilized or stored by those who receive the poultry waste from the permitted farm including poultry waste brokers. Concentrated Animal Feeding Operations (CAFOs) are AFOs that meet a specific number and type of confined animals, certain CAFOs may be required to obtain a VPDES CAFO individual permit. Of the 1047 farms covered by a DEQ permit, there are 127 farms covered under the AFO general permit, 911 farms covered under the poultry waste general permit, eight farms covered by the VPDES CAFO individual permit and 1 farm covered by the VPA AFO individual permit.

VPDES Compliance Inspection Program

The DEQ Virginia Pollutant Discharge Elimination System (VPDES) Permit program, the Pretreatment program, the Virginia Pollution Abatement (VPA) Permit program, and the VPDES and VPA general permit program rely primarily on the concept of permittee self-monitoring and reporting for compliance determinations. To insure proper operation and maintenance of facilities and confirm self-monitoring information is representative and accurate, the DEQ conducts facility inspections as the principal form of regulatory compliance surveillance. The DEQ utilizes a risk-based protocol to identify facilities needing increased or decreased inspection frequency and/or complexity while using staff resources most effectively to accomplish inspection goals.

Inspection Program Objectives

The objectives of the inspection program are:

- to assure that facilities are in compliance with statutes, regulations, and permit requirements, thereby protecting the quality of state waters
- to improve facility performance by providing advice and assistance,
- to support permit development,
- to maintain a regulatory presence,
- to support administrative, civil, and criminal enforcement actions,
- to support development and implementation of the pretreatment program.

Each inspection of a wastewater treatment facility will not accomplish every objective but most inspections are useful in accomplishing several of the above objectives. Therefore, inspection frequencies are scheduled to provide maximum coverage of facilities within available DEQ resources. See Table 7.1-1. Additionally, inspections can be a scheduled or unscheduled activity in response to public complaints or requests from outside DEQ.

Table 7.1-1 Inspection frequency by facility type

INSPECTION FREQUENCY			
Inspection Type	**Annually**	**Biennially**	**5 Years**
VPDES Municipal Major (≥1.0 MGD)		**X**	
VPDES Municipal Minor (≥0.04 & ≤1.0 MGD)		**X**	
VPDES Municipal Small (≥0.001 & ≤0.04 MGD)			**X**
VPDES Industrial Major (DEQ/EPA Majors list)		**X**	
VPDES Industrial Minor (not a Major or Small)		**X**	
VPDES Industrial Small [2]			**X**
VPDES General			**X**
VPDES Sampling [3]			**X**
VPG (AFO)	**X**		
VPA (High Priority) [4]	**X**		
VPA (Low Priority)[5]			**X**
Commercial Laboratory (Major)[6]	**X**		
Commercial Laboratory (Minor)[7]		**X**	

1 Includes multiple home and non-residential domestic wastewater facilities covered by General Permit.

2 Small is an industrial facility with low environmental impact potential such as discharges of non-contact cooling water, sand and gravel operations, car washes, etc.

3 Sampling inspections are conducted subject to the availability of effluent.

4 High priority is assigned to facilities with high environmental impact potential or high public concern and includes animal feeding operations, wood preserving operations, sludge disposal activities, and other facilities so classified by the Regional Offices. An inspection of sludge disposal permitted facilities includes, as a minimum, an inspection of the storage facilities and at least one land application site per permitted facility per year.

5 Low Priority is a VPA facility with low environmental impact potential.

6 Major Commercial Laboratories are those who serve ten or more minor VPDES/VPA permittees and/or 1 major facility.

7 Minor Commercial Laboratory designation is assigned to all other facilities not considered as high priority.

Water Quality Planning and TMDLs

DEQ uses Water Quality Management Plans (WQMPs), required by section 303(e) of the Clean Water Act, as the link between the water quality assessment required for this report and water quality based controls. These plans recommend control measures for the water quality problems identified and characterized in the 305(b) report. Control measures recommended in the plans are implemented through the VPDES permit system for point sources and through the application of Best Management Practices (BMPs) for nonpoint sources. WQMPs establish the strategy for returning impaired waters to meet water quality standards and for preventing the degradation of high quality waters.

Section 303(d) of the 1972 Clean Water Act requires the states to identify waters not in compliance with water quality standards, establish priorities, develop a biennial list of the impaired waters, and develop Total Maximum Daily Loads (TMDLs) for the waters on the 303(d) list. In July 1992, EPA promulgated regulations, 40 CFR 130.7, for 303(d) of the CWA. TMDLs were to be implemented through existing pollution reduction regulations and voluntary strategies.

The State Water Control Law, Chapter 3.1, Article 1 of the Code of Virginia, authorizes the State Water Control Board to control and plan for the reduction of pollutants impacting the chemical and biological quality of the state's waters that result in the degradation of designated uses.

In 1997, the Virginia General Assembly enacted the Water Quality Monitoring, Information, and Restoration Act, §62.1-44.19:4 through 19:8 of the Code of Virginia. This statute directs DEQ to develop a list of impaired waters and develop TMDLs for these waters. Also, the state statute directs DEQ to develop implementation plans for the TMDLs.

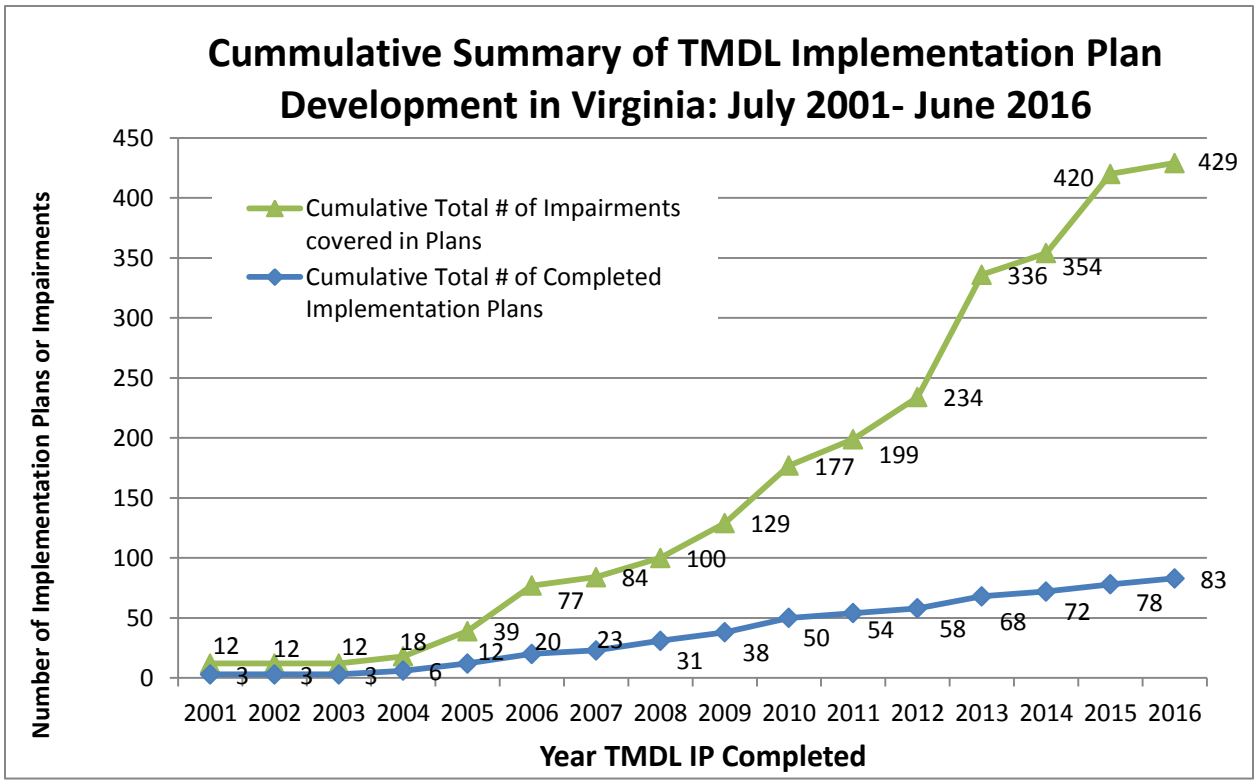
TMDL Development and Implementation Plan Development

In 1998, the American Canoe Association and the American Littoral Society filed a complaint against EPA for failure to comply with the provisions of §303(d) of the CWA in Virginia. In 1999, EPA signed a Consent Decree (CD) with the plaintiffs. The Consent Decree contained a TMDL development schedule through year 2010. This schedule required a TMDL to be developed on the approximately 475 impaired waters and the approximately 225 condemned or restricted shellfish waters identified in Virginia's 1998 303(d) list. Many of these impaired waters were impaired by more than one pollutant.

Since completing the requirements of the 1999 CD, Virginia continued to develop approximately 50 TMDLs per year in accordance with a TMDL Development pace agreement with EPA. As of 2016, Virginia developed a list of priority waters for TMDL or TMDL alternative development. All waters on this priority list are intended to be addressed by a TMDL or TMDL alternative by 2022. For more information on the prioritization process, please see Chapter 7.2 of this report. Virginia currently develops TMDLs using a "watershed approach" when possible. The watershed approach to TMDL development allows watersheds with similar characteristics to be combined under a single TMDL equation or report resulting in cost and time efficiencies. Watersheds are prioritized for TMDL development based on risk, public interest, available monitoring, regional input, and available funding. TMDL development schedules are developed about every two years, and posted on Virginia's TMDL website: http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/TMDL/TMDLDevelopment.aspx.

A TMDL Report is a special study to determine the amount of a pollutant that the impaired water can assimilate and still meet water quality standards. Additionally, the TMDL report will identify all sources of pollution contributing to the violation of water quality standards and calculate the pollutant amount entering the stream from each source and calculate acceptable pollutant loads needed for attainment of Water Quality Standards.

Once a TMDL is developed, the study report is submitted to the State Water Control Board and the



USEPA for approval. Virginia law (1997 Water Quality Monitoring, Information, and Restoration Act, §62.1- 44.19:4 through 19:8 of the Code of Virginia), or WQMIRA, requires the development of a TMDL implementation plan after a TMDL is developed and approved. There is not a mandated schedule for implementation plan development; however, local or state agencies, as well as community watershed groups partner with DEQ in developing TMDL implementation plans. The implementation plan describes the measures that should be taken to reduce pollution levels in the stream and includes a schedule of actions, costs, and monitoring. During its 2013 Legislative Session, the General Assembly passed Chapters 756 (HB2048) and 793 (SB1279) of the 2013 Virginia Acts of Assembly which designated, effective July 1, 2013, the Virginia Department of Environmental Quality as the lead agency for nonpoint source programs in the Commonwealth of Virginia. Effective July 1, 2013 DEQ has the lead for the entire TMDL program, including implementation, for the Commonwealth of Virginia. Information about the TMDL Implementation Program, including success stories and available funding for implementation of Best Management Practices, can be found here http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/TMDL/TMDLImplementation.aspx

[1] As of May 1, 2016 VADEQ has received EPA approval for 0 TMDLs completed for FY16 although 33 were under preparation.

Figure 7.1.-1 TMDL Implementation Plan Development in Virginia

No Discharge Zone Program

No Discharge Zones (NDZs) are one tool for remediating bacterial contamination, particularly in smaller, poorly-flushed tidal Chesapeake Bay tributaries. This remediation tool is recommended in all tidal TMDLs where shellfish are present. Under the Clean Water Act, discharge of untreated sewage is illegal. NDZs are federally designated areas where this prohibition is extended to discharge of any vessel sewage. States seeking this designation for a water body must demonstrate to EPA that 1) adequate local disposal alternatives (such as marina-based pump-outs) exist, and 2) the designation protects natural resources.

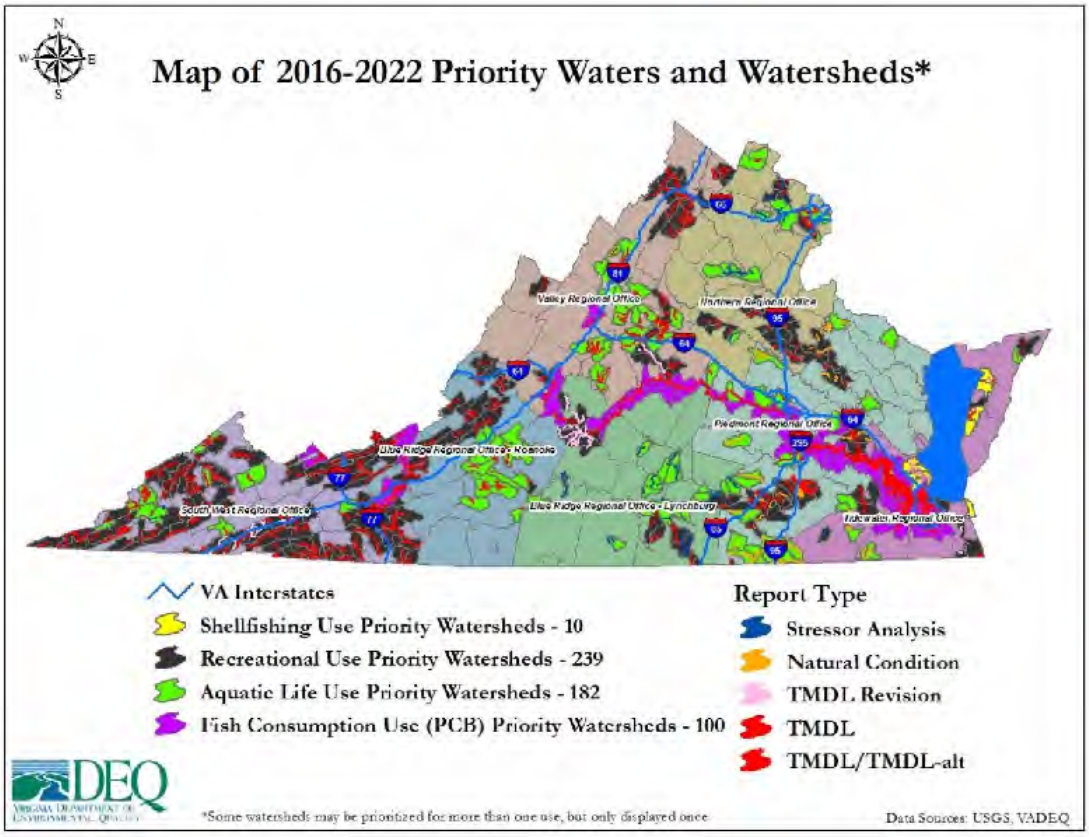
In Virginia, DEQ is the coordinating agency for the preparation of NDZ applications and their submittal to EPA. Applications may be initiated as a component of a TMDL implementation plan or by request from the public. The application process includes coordination with other state agencies, analyses to estimate peak-season boat traffic for the area under evaluation, and an assessment of the existence and adequacy of all available disposal alternatives. The process also includes intensive public outreach to solicit and strengthen local support to elevate boaters' awareness of the importance of controlling bacteria sources. Once established, the designation is indicated by prominent on-the-water signage.

The Code of Virginia (§ 62.1-44.33) establishes all tidal creeks of the Commonwealth as NDZs where vessels may be prohibited from discharging treated or untreated waste into Virginia's waters. The Code further states that the establishment of an NDZ is to be premised on the improvement of impaired tidal creeks. For more information about Virginia's No Discharge Zone Program, including currently established NDZs, please visit http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/TMDL/NoDischargeZoneDesignations.aspx

CHAPTER 7.2 IMPLEMENTING THE CLEAN WATER ACT 303(d) PROGRAM VISION

The Clean Water Act 303(d) Program Vision was announced by EPA in collaboration with the states in December 2013. While this Program Vision provides a new framework for implementing the 303(d) program, it is not a new rule or regulation and does not impose any new legal requirements on EPA, Virginia, or other stakeholders. Furthermore, it does not change any of the requirements or authorities of Virginia or EPA under the Clean Water Act section 303(d). Overall the new Vision introduces six new program enhancements with an emphasis on improving overall efficiency of the 303(d) program. The six program enhancements are addressed through the six Vision goals that include prioritization, assessment, protection, alternatives, engagement, and integration. The detailed Vision goals are described below:

1. "Prioritization" For the 2016 integrated reporting cycle and beyond, States review, systematically prioritize, and report priority watersheds or waters for restoration and protection in their biennial integrated reports to facilitate State strategic planning for achieving water quality goals.
2. "Assessment" By 2020, States identify the extent of healthy and Clean Water Act Section 303(d) impaired waters in each State's priority watersheds or waters through site-specific assessments.
3. "Protection" For the 2016 reporting cycle and beyond, in addition to the traditional TMDL development priorities and schedules for waters in need of restoration, States identify protection planning priorities and approaches along with schedules to help prevent impairments in healthy waters, in a manner consistent with each State's systematic prioritization.
4. "Alternatives" By 2018, States use alternative approaches, in addition to TMDLs, that incorporate adaptive management and are tailored to specific circumstances where such approaches are better suited to implement priority watershed or water actions that achieve the water quality goals of each state, including identifying and reducing nonpoint sources of pollution.
5. "Engagement" By 2014, EPA and the States actively engage the public and other stakeholders to improve and protect water quality, as demonstrated by documented, inclusive, transparent, and consistent communication; requesting and sharing feedback on proposed approaches; and enhanced understanding of program objectives.
6. "Integration" By 2016, EPA and the States identify and coordinate implementation of key point source and nonpoint source control actions that foster effective integration across Clean Water Act programs, other statutory programs (e.g., CERCLA, RCRA, SDWQ, CAA), and the water quality efforts of other Federal departments and agencies (e.g., Agriculture, Interior, Commerce) to achieve the water quality goals for each state.



Virginia is well on track to meet and implement all six goals of the new Clean Water Act 303(d) Program Vision. The following sections of this chapter will detail Virginia's progress towards these Vision goals.

Prioritization

DEQ is currently implementing the national 303(d) Program Vision which calls for the prioritization of impaired waters for TMDL or TMDL alternative development over a six year window (currently 2016-2022). A description of the process and a list of waters with city/county information can be found at http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/TMDL/TMDLDevelopment/TMDLProgramPriorities.aspx. Additionally, in the 303(d) list (Appendix 1a), the 2016-2022 priorities are denoted by "H" or "M" under the "TMDL Priority" column for high and medium priority. As part of the 303(d) Vision, DEQ submitted formal priorities to EPA that will be addressed with TMDLs or TMDL-alternatives by 2022. The priorities that were public noticed also included internal priorities that DEQ will aim to address with TMDLs, TMDL-alternatives, stressor analyses, or natural conditions reports by 2022. In the 303(d) list the priority waters formally submitted to EPA are the waters that have an "H" under the "TMDL Development Priority" column. The DEQ internal priorities, with the exception of those prioritized for natural conditions reports, are the waters that have an "M" under the "TMDL Development Priority"

column. Waters prioritized for Natural Conditions Reports receive a TMDL priority ranking of "L" for low since no TMDL or TMDL-alternative will be developed. While TMDL-alternatives may be pursued for any priority water, the decision between TMDL and TMDL-alternative development will be made at the onset of the study. For more information on TMDL-alternatives, see the section titled "Alternatives" below. In some instances, for a variety of reasons, the priority ranking of an impaired assessment unit may change from the list that was originally public noticed. One example of this occurrence is when a TMDL project is initiated for priority waters and it is realized that other potentially new impairments exist in the watershed. Since the TMDL project will address all of the impairments, the formerly low priority waters will change priority to match the priority of the waters that the project originally sought to address.

The resulting map of priority waters and watersheds is shown below (**Figure 7.2-1**).

One aspect is important to note: For the prioritization of waters with an impaired aquatic life use, DEQ looked at waters that were impaired by 1) low dissolved oxygen concentrations, 2) high or low pH levels, 3) high temperatures in coldwater streams, and 4) impairments to the benthic macroinvertebrate communities. Since these impairments result in impacts to the aquatic ecosystem, DEQ sought to prioritize waters impaired for the aquatic life use where additional benefits to aquatic ecosystems could be gained. In order to maximize these additional benefits DEQ conducted a statewide analysis of small watersheds (specifically 6th order Hydrologic Units) that contained waters impaired for one or more of the 4 reasons listed above in addition to waters that contained one or more of the following criteria:

1. The presence of a state and/or federally listed threatened or endangered species (spatial data provided by DGIF)
2. The presence of a DCR Stream Conservation Unit, which is based on:
   - The presence of a rare, threatened, or endangered species; or
   - The presence of an aquatic ecological community of high integrity

Since all TMDLs are designed to protect the watershed for which they are developed, the idea was that in developing a plan to restore waters impaired for the aquatic life use, other state and federal goals of protecting rare, threatened, or endangered species and ecological communities of high integrity could also be implemented. In this regard, the 303(d) Program Vision goal #3 “Protection” and #6 “Integration” were also addressed.

Assessment

Since the beginning of the TMDL program at DEQ, efforts have been made to coordinate TMDL development and water quality monitoring. Through these efforts, the appropriate water quality data was gathered to aid in the development of TMDLs. As part of the 303(d) Program Vision, the process of prioritizing waters for TMDL and TMDL alternative development over the next 6 years (2016-2022) has improved the process of water quality monitoring plan development by making the long-term plan more predictable.

Furthermore, in an effort to better plan for TMDLs or TMDL alternatives that address benthic macroinvertebrate impairments, DEQ staff are working to specify the group of parameters necessary for pre-TMDL monitoring. Because TMDLs must be developed for pollutants causing an impairment, TMDLs or TMDL alternatives that address benthic macroinvertebrate impairments require an analysis to determine what stressors (i.e., pollutants) are causing the impairment. Currently this analysis is done using all available data. The aim for this initiative is to provide the proper suite of parameters that will aid in a thorough analysis of potential stressors causing the impairment of the benthic macroinvertebrate community.

It is through these more coordinated efforts that DEQ believes it is on track to identify the extent of the impairments for each of Virginia’s priority waters through site specific assessments.

Protection

Due to the numerous water quality impairments across Virginia, DEQ is committed to addressing impaired waters. Other state agencies such as DCR take the lead in developing plans to protect “healthy waters.” While DEQ does not take the lead in developing these plans, the general concept of protecting waters and maintaining the anti-degradation policies for water quality is well-addressed through numerous DEQ programs and initiatives.

Already noted in the “Prioritization” section of this chapter was the dual benefit of protecting rare, threatened, or endangered species and aquatic ecological communities of high integrity through the prioritization of watersheds for TMDL or TMDL alternative development that contain these qualities in addition to downstream aquatic life use impairments. Furthermore, DEQ accepts nominations for Exceptional State Waters (Tier III), which the State Water Control Board approves if such nominations qualify as waters in a location of outstanding scenic beauty, have exceptional aquatic communities, and/or have superior recreational opportunities. This Tier III designation prohibits permanent new or increased discharges from point sources, maintaining a strong anti-degradation policy.

It is also worth noting that DEQ is evaluating an additional metric to assess benthic macroinvertebrate communities in Virginia streams, the Biological Condition Gradient (BCG). The BCG will categorize the diversity and abundance of macroinvertebrates sampled in streams and group them into categories along a 6-scale gradient of ecological stress. The BCG categories are determined by scientific decision criteria based on biological responses to anthropogenic stress. In other words, the BCG is a model that describes how the biota of stream ecosystems change with increasing anthropogenic stress. The BCG, once established in a particular ecoregion, offers a framework to help characterize the degree of stress on the aquatic system along a 6-scale gradient and to recognize incremental improvements in meeting water quality goals. Virginia will continue to use the Virginia Stream Condition Index (VSCI) score to determine whether or not a stream is impaired for the aquatic life use.

Alternatives

DEQ is currently exploring opportunities for TMDL alternative development. In certain circumstances the use of a TMDL alternative may offer more assurances that impaired waters will be restored in either a more timely or practical manner. As a result of the process described in the "Prioritization" section above, DEQ has listed 27 impairments on the priority list (Appendix 1a) where a TMDL alternative may be the best option for addressing the impairment. The ultimate decision on whether or not to pursue a TMDL or a TMDL alternative will be made by DEQ staff in conjunction with the technical advisory committee for the project at the onset of the project. Therefore, on the priority list found on the TMDL Program Priorities webpage these impairments are listed with a "Report Type" of "TMDL/TMDL-alt." Similarly, in Appendix 1a these waters are still considered for TMDL development and will be listed with an "H" or an "M" under the "TMDL Priority" column. Although these 17 impairments are prioritized considering the potential for pursuing a TMDL alternative, other impairments on the priority list may be addressed with TMDL alternatives. If a TMDL alternative is pursued, it will follow the same public participation process as a TMDL or TMDL implementation plan (see the "Engagement" section below), and will be briefly explained in this chapter of successive 305(b)/303(d) Integrated Reports. Furthermore, unless the alternative has enforceable pollution control requirements, the impaired water addressed with a TMDL alternative will remain in category 5, but be moved from subcategory 5A to subcategory 5R – "The water quality standard is not attained and the water is impaired, and implementation of an EPA-accepted restoration plan is expected to result in attainment." If the alternative does have enforceable pollution control requirements, the impaired water addressed will move to category 4B – "water is impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements are reasonably expected to result in attainment of the water quality standard by the next reporting period or permit cycle." The waters with alternative restoration plans that are moved to subcategory 5R will remain in category 5 until water quality standards are attained. These waters are assigned lower priority for TMDL development as alternatives designed to achieve water quality standards are implemented in the near term. If water quality standards are not fully attained through alternative approaches, development of a TMDL would be necessary.

DEQ currently has 1 TMDL alternative in the Potomac-Shenandoah River Basin that is category 5R. It is the watershed plan to address the Fairview Beach recreational impairment due to excessive levels of bacteria. The TMDL alternative was pursued in this case due to the reasons listed below:

- The impaired area is very small and the local drainage area contributing to the swimming area is 1-2 mi^2.
- There are no point sources contributing to the excessive levels of bacteria, so the regulatory TMDL waste load allocation would not provide any significant load reductions in the watershed.
- Several pollution control measures are already implemented or are soon to be implemented.
- The stakeholder involvement in the watershed is strong, which should ensure success in implementing the voluntary pollution control measures necessary to meet water quality standards.

The Fairview Beach Watershed Plan can be found here:
http://www.deq.virginia.gov/Portals/0/DEQ/Water/TMDL/ImplementationPlans/FB_WP.pdf

Engagement

In the fall of 2014, DEQ finalized the revised Public Participation Procedures for Water Quality Management Planning guidance document. These procedures set forth the process to provide the public and stakeholders with an adequate opportunity to participate in the development and implementation of TMDLs, TMDL modifications, 305(b)/303(d) Integrated Reports, priority schedules for TMDL and TMDL alternative development, and non-TMDL waste load allocations. These procedures also exempt any of these actions from the full Administrative Process Act public participation process because they go above and beyond those requirements. For the development of TMDLs and TMDL Implementation Plans, stakeholders will have a minimum of two opportunities to provide comments. Stakeholders will also have a final opportunity to comment on TMDL projects prior to State Water Control Board Approval.

Opportunities for public comment also exist for the draft 305(b)/303(d) Integrated Report, the draft guidance for the 305(b)/303(d) Integrated Report, draft priority schedules for TMDL and TMDL alternative development, draft TMDL modifications, and non-TMDL waste load allocation development or modifications. It is the goal of these procedures to include stakeholders in water quality management actions from the initial listing of an impaired water, all the way to the implementation of the TMDL or TMDL alternative developed to address the impairment.

Stakeholders interested in participating in these water quality actions can see public notices for these actions in the Virginia Register, the Virginia Regulatory Town Hall, or on DEQ's website. In particular, public notices pertaining to the priority schedule for TMDL and TMDL alternative development, TMDL related regulatory actions, and TMDL and TMDL Implementation Plan development can be found at the DEQ TMDL Public Notices webpage.

Integration

Virginia's efforts towards program integration were aided with the migration of stormwater and nonpoint source programs from DCR to DEQ in July 2013. TMDL and TMDL Implementation Plan development programs, in addition to the grants management program for projects implementing the TMDL Implementation Plans, are now combined in one DEQ program office. With MS4 permitting now also at DEQ, this allows for close intra-agency collaboration on emerging concepts and approaches for addressing MS4 permits in TMDL watersheds. This collaboration is an ongoing effort to continuously improve DEQ's management of stormwater in watersheds with impaired waters.

DEQ also collaborates with VDH who conducts the beach monitoring program for Virginia. The data collected by the beach monitoring program is used by VDH to issue swimming advisories. That same data helps DEQ determine beach recreational use impairments, in addition to aiding the development of TMDLs and TMDL alternatives to address beach impairments. DEQ and VDH also have integrated efforts related to shellfish harvesting and shellfishing impairments. The VDH Division of Shellfish Sanitation conduct water quality monitoring and shoreline surveys in order to determine whether or not shellfish growing areas are suitable for shellfish harvesting. As a result of this data, DEQ then determines whether or not the shellfishing use is impaired. When it is impaired, this data is also considered during the TMDL or TMDL alternative development. Furthermore, the DEQ fish tissue monitoring program provides the data that VDH uses to determine fish consumption advisories. DEQ then uses the extent of the fish consumption advisories to assess the extent of state waters with fish consumption use impairments. Through the beach monitoring program and the Division of Shellfish Sanitation at VDH, and the fish tissue monitoring program at DEQ, VDH and DEQ partner to notify the public of public health related impairments, while also providing the information necessary to address these impairments with TMDLs and TMDL alternatives.

Additional integration efforts include:

- Spearheading work to integrate land division, water permitting division and water planning division efforts for addressing PCB fish tissue contamination issues.
- The aforementioned work between monitoring staff and TMDL staff to specify parameters necessary for conducting thorough stressor identification analyses in waters with benthic macroinvertebrate impairments that are prioritized for TMDL or TMDL alternative development.
- The aforementioned collaboration between DCR and DEQ for prioritization of watersheds for TMDL or TMDL alternative development that have both aquatic life use impairments and waters with ecological communities of high integrity and/or rare, threatened or endangered species.

CHAPTER 7.3 POLLUTION PREVENTION (P2) and ENVIRONMENTAL MANAGEMENT SYSTEMS

Pollution Prevention

"Pollution prevention" (or P2) is recognized by the US EPA as the most cost-effective form of environmental protection because it is an environmental management strategy that emphasizes the elimination or reduction of wastes at the source of their generation. Traditional waste management techniques such as treatment, disposal, and recycling concentrate on managing wastes after they are generated. P2 focuses on the question, "why are the wastes produced in the first place?"

Wastes are essentially wasted raw materials, and P2 efforts strive to identify opportunities to conserve and use raw materials as efficiently as possible. In addition, P2 stresses the reduction of toxicity and prevention of spills and raw material/product losses whenever possible. By definition, P2 is distinguished from recycling and reuse efforts because these management techniques involve waste handling, collection, and reprocessing into a new raw material or useable product. True P2, which is often referred to as "source reduction," eliminates or reduces the need for additional waste handling and the costs associated with that process. As such, P2 can result in significant cost savings while reducing overall environmental impacts and liabilities and facilitating compliance with environmental regulations.

Environmental Management Systems

Many facilities that understand the value of P2 have realized that the environmental impacts of their operations are not just a by-product of what they do, but an integral part of their business model that affects the very success or failure of their organization. These facilities have embraced the development of an "environmental management system" (EMS) to ensure that the environment is considered in all facets of the company's operations. A successful EMS sets goals for implementation of P2 and other projects that will enable "continuous improvements" in the facility's environmental performance year after year. Compliance with environmental regulations is assumed as a starting point for facilities with an EMS in place, and the EMS drives companies to focus on reducing environmental impacts rather than maintaining compliance.

What Do "P2" & "EMS" Mean for Water Quality?

P2 & EMS are good news for water quality as they offer cost-effective opportunities for reducing water contamination. P2 techniques offer excellent applications for reductions in water usage, chemical and nutrient inputs to wastewater, treatment, and stormwater minimization and management. EMSs will ensure that P2 techniques are considered and employed whenever possible as part of the facility's normal business process. Compliance with water quality standards will be the beginning point, and they will strive to continuously do better than those standards.

DEQ's Office of Pollution Prevention

The Virginia DEQ's Office of Pollution Prevention (OPP) is a non-regulatory program that promotes the use of voluntary pollution prevention approaches and technologies and the use of EMSs. OPP has developed a variety of voluntary programs and partnerships to encourage facilities that are interested in doing more than the minimum as required by regulations. These programs provide public recognition and award opportunities, assistance, and even regulatory incentives for participating.

<u>Voluntary Programs</u>

The ***Virginia Environmental Excellence Program (VEEP***) is DEQ's program to promote the voluntary use of environmental management systems (EMS) and pollution prevention (P2). VEEP offers recognition and regulatory incentives to

encourage facilities to develop and implement an EMS. For instance, wastewater treatment plants that participate in VEEP actually receive a discount on their annual permit fees. More than 600 Virginia facilities have been designated as VEEP facilities. For more information, see http://www.deq.virginia.gov/Programs/PollutionPrevention/VirginiaEnvironmentalExcellenceProgram.aspx.

Virginia Green is DEQ's voluntary initiative to promote pollution prevention practices all aspects of Virginia's tourism industry. *Virginia Green* is run in partnership with the Virginia Tourism Corporation and the Virginia Hospitality & Travel Association. There are more than 1400 facilities who have met the minimum criteria for Virginia Green. For more information, go to http://www.deq.virginia.gov/Programs/PollutionPrevention/VirginiaGreen.aspx.

Virginia Information Source for Energy (VISE) is DEQ's project to promote energy efficiency, conservation, and renewable energy technologies. DEQ maintains a website on energy-related technologies, conservation techniques and financial incentives at http://www.deq.virginia.gov/Programs/PollutionPrevention/VirginiaInformationSourceForEnergy.aspx.

For more information on DEQ's P2 and EMS programs, contact Sharon Baxter at 804-698-4344 or sharon.baxter@deq.virginia.gov.

CHAPTER 7.4 COST/BENEFIT ASSOCIATED WITH THE CONSTRUCTION ASSISTANCE PROGRAM

Construction Grants

The Federal construction grants program was initiated in 1958 to provide financial assistance to municipalities for the planning, design, and construction of publicly owned treatment works. Until 1988, the program was an essential element in pollution control efforts, without which many localities would have been unable to provide wastewater treatment systems.

Through 1988, Virginia received approximately $1.2 billion in federal appropriations for construction grants. These federal funds financed up to 75% of the total eligible cost of approximately 183 projects. The state contributed another $52.3 million toward project costs, with the remainder coming from local sources. Total local investment in these projects is estimated at $500 million.

Virginia Clean Water Revolving Loan Fund

In 1988, a grant program was converted to a low-interest loan program to provide financial assistance for the planning, design and construction of POTW's. The 1986 General Assembly created the Virginia Water Facilities Loan Fund, through which loans could be made to local governments at or below current market interest rates for wastewater treatment improvements. Principal and interest repaid into the fund could then be loaned again for additional projects. The Federal Water Quality Act of 1987 established a State Revolving Loan Fund Capitalization Grant Program that provided an avenue for states to convert federal grant monies into a State Revolving Loan Fund.

On June 10, 1988, Virginia became the first state in EPA Region III and the fifth state in the nation to receive authorization to administer a State Revolving Loan Program. As of June 30, 2016, Virginia has received federal capitalization grants totaling $935,649,207. In addition, Virginia has provided the required matching funds of $171,088,383 to the program.

These funds, along with accrued interest earnings, repayments by loan recipients, and the implementation of a leveraging program in each of FY's 1999, 2000, 2004 and 2007 through 2013 (when demand exceeded available resources) have enabled the VRLF to provide loan assistance to 986 projects totaling over $3 billion.

AgBMP Loan Program

The 1999 General Assembly amended Chapter 22 of the Code of Virginia, expanding the activities of Virginia's Water Facilities (Clean Water) Revolving Fund, to allow low interest loan financing of specific agricultural best management practices (AgBMP). This legislation was amended to encourage the Commonwealth's farm communities to implement best management practices that reduce or eliminate agricultural non-point source pollution of Virginia's waters. This funding initiative went into effect July 1, 1999. Agreements were reached with the Virginia Resources Authority and the State's three Farm Credit Associations to allow them to perform necessary loan underwriting and execute and disburse loan proceeds to the recipients.

Virginia received its first request for low-interest loan assistance from its AgBMP program on January 14, 2000. Since then, DEQ has authorized more than $46 million in low-interest loan assistance to Virginia farmers for over 614 eligible BMP projects that would improve water quality in the Commonwealth.

Brownfield Program

The 2001 General Assembly amended the VRLF legislation to make loan assistance available for remediation of contaminated brownfield properties across the Commonwealth. This funding initiative

provides assistance to eligible entities for activities that result from an approved site characterization and remediation plan and where the remediation effort results in an improvement to or protection of surface or groundwater. As of June 30, 2016, six loans for brownfield projects have been closed totaling $4,487,349.

Land Conservation Loan Program

The 2003 General Assembly enacted legislation that expanded the activities of the fund by allowing Virginia to authorize low-interest loans for acquisition of title or other rights to real property when the Board was satisfied that the acquisition would protect or improve water quality and prevent pollution of state waters. The legislation provided that financing for land acquisition would be available only in those fiscal years when all other eligible loan requests from local governments had been satisfied. This program was included in each of the FY 04 through FY 16 loan solicitations and nine loans have been closed totaling $33,620,951. Table 7.2-1 summarizes Revolving Loan Fund cumulative status as of June 30, 2016.

Table 7.4 -1 Summary of Revolving Loan Fund Status

	Number	Amount
Section 212 Loans Closed*	**411**	**$ 2,821,039,275**
ARRA Loans Closed	**35**	**77,720,311**
Ag BMP Loans Closed	**491**	**$ 46,510,711**
Additional Section 319 Loans Closed	**21**	**$ 38,270,499**
Section 212 Loans Approved (not closed as of 6/30/2015)	**24**	**$ 97,028,478**
Ag BMP Loans Authorized (not closed as of 6/30/2015)	**0**	**$ 0**
Additional Section 319 Loans Approved (not closed as of 6/30/2015)	**4**	**$ 4,960,925**
TOTAL	**986**	**$ 3,085,530,199**

* *Includes projects funded with loan payments, leveraged bond proceeds, and amounts utilized for Program Administration.*

The impact of Virginia's loan program on water quality and public health can be summarized as follows:

- Eliminated Virginia's 12 remaining municipal "primary discharge" treatment plants
- Upgraded or replaced 38 inadequate municipal wastewater treatment lagoon systems
- Upgraded, expanded or replaced 171 outdated public wastewater treatment facilities
- Eliminated 235 major points of raw sewage overflows
- Improved water quality at 152 projects by significantly reducing infiltration/inflow loading to the plants and the receiving streams
- Addressed 62 potential community public health hazard situations by eliminating failing septic systems, pit privies and straight-line discharges through the construction of public sewer

systems

- Installed nutrient removal technology at 50 municipal treatment facilities discharging to the Chesapeake Bay
- Established 5 local loan programs for the replacement/rehabilitation of individual on-site wastewater treatment systems
- Conserved 10,717 acres of land, thereby protecting water quality in the associated watersheds
- Installed 9 water reuse projects
- Provided alternative energy production projects at 14 wastewater treatment facilities
- Installed new stormwater management systems at 9 projects

As of June 30, 2016, the Department of Environmental Quality's Ag BMP Loan Program had provided 491 low interest loans to Virginia farmers to assist them with implementation expenses related to the following 614 agricultural best management practices (see Table 7.2-2).

Table 7.4-2 Number of BMPs funded by the AgBMP Loan Program

BMP ID #	BMP Name	# of each BMP implemented at Farm Operation Type							Total Funded
		Dairy	Poultry	Beef	Swine	Sheep	Horse	Row Crop	
WP-6	Ag Chemical & Fertilizer Handling Facility							2	**2**
SL-6B	Alternative Water System	1		3		1			**5**
WP-4	Animal Waste Control Facility	84	88	60	1	1	1	1	**236**
WP-4E	Animal Waste Structure Pumping Equipment	18		1	9				**28**
WP-4C	Composter Facility	1	50		3				**54**

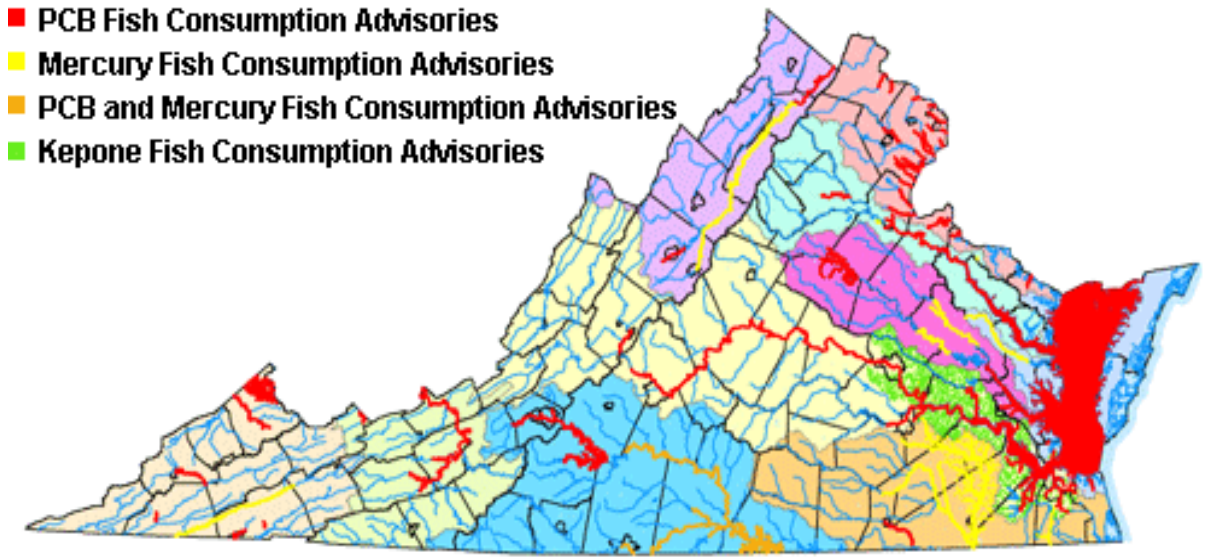
								Total BMPs Loan Funded =	**614**

CHAPTER 7.5 PUBLIC HEALTH/AQUATIC LIFE CONCERNS



DEQ continues to address the role toxicants play in reducing water quality in state waters and supports programs to monitor, evaluate, and reduce toxicity to aquatic life and human health. Many of the programs in place at DEQ that address toxicity in state waters are described and discussed throughout this report.

The toxic pollutants that were monitored during the reporting period include toxic organics, metals and pesticides. Information on the state's monitoring programs and the results of this monitoring for toxics in water column, fish tissue, and sediment is provided in Chapters 3 and 4 of this report.

Fish Consumption Advisories and Restrictions

Virginia's fish consumption advisories are reviewed annually by the Virginia Department of Health (VDH). VDH has 64 health advisories in effect as of 2010. A health advisory warns of potentially dangerous levels of contamination found in fish tissues in an affected area and, in most cases, limits consumption but does not prohibit it. Under health advisories, the population at risk and a safe maximum consumption rate may be specified. All VDH fish consumption advisories for mercury and PCBs caution that women who are pregnant or may become pregnant, nursing mothers and young children should not eat any fish from affected waters to avoid ingesting contaminants. Contamination of fish by three toxic pollutants – (kepone, mercury, and polychlorinated biphenyls (PCBs) - have been the causes of the health advisories that are currently in place throughout the state. Four of the health advisories (kepone in the lower James River, mercury in the North Fork Holston River, mercury in the South River and sections of the Shenandoah River, and PCBs in the South Fork Shenandoah River, North Fork Shenandoah River and Shenandoah River) were the result of accidental industrial releases of toxic contaminants to the aquatic environment, while the contributing sources of contamination for the remainder of the advisories remain under investigation, primarily through TMDL studies and subsequent activities. The history of the four known industrial releases and general information about the fish consumption advisories is discussed below. The health advisories and affected watersheds can be found at this VDH link: http://www.vdh.virginia.gov/environmental-epidemiology/public-health-toxicology/fish-consumption-advisories/

A map showing the current fish consumption advisories is shown below (**Figure 7.5-1**):

For questions about human health risks from exposure to fish contaminants, please contact the Virginia Department of Health (VDH) at (804) 864-8182. For general questions about fishing regulations in Virginia, please call Game and Inland Fisheries at (804) 367-1000, or visit the DGIF webpage. For further information regarding the fish tissue sampling and analysis process, please contact the Department of Environmental Quality at (804) 698-4000, or visit the DEQ webpage.

Kepone in the Lower James River

From 1966 through 1975, Allied Chemical Company and its subsidiary Life Science Products, Inc. produced a persistent chlorinated hydrocarbon insecticide called Kepone. During production, an estimated 90,720 kg of Kepone was released to the environment through atmospheric emissions, wastewater discharges, and bulk-disposal of off-specification batches. The James River and its tributaries from Richmond to Newport News were contaminated with Kepone. In 1975, the entire James River from the fall line at Richmond to the Hampton Roads/Norfolk Bridge Tunnel, including all tributaries, was closed to the taking of any shellfish and/or finfish because of Kepone. From 1975 through 1988, various Kepone bans were in place. In 1988, all James River fishing restrictions due to Kepone were allowed to expire as Kepone levels in fish remained below the U.S. Food and Drug Administration (FDA) action level of 0.30 parts per million (ppm). This area, covering the main stem James River and all tributaries from the fall line at Richmond to the Hampton Roads-Norfolk Bridge Tunnel, is currently under a contaminant advisory. The Kepone advisory cautions anglers to limit the consumption of all species of fish from this part of the river to one meal per day. However, a more stringent consumption advisory due to PCBs has been in place since 2002 for portions of the same segment and anglers are advised to follow this advisory.

DEQ continually monitored Kepone levels in the James River since its identification in 1975 until 2009. The major areas of concern were Kepone levels in the water column, finfish, and sediment of the James River and its tributaries, and in the ground water in Hopewell. After continuous non-detectable results, water column monitoring was discontinued in 1981. Kepone levels in finfish, ground water, and sediment have decreased since the onset of the problem. The VDH has established a level of concern of 0.30 ppm Kepone in edible fish filet samples. The concentrations of Kepone in fish filet samples from this section of the James River watershed have not exceeded this level of concern since 1996.

Fish consumption advisories due to mercury contamination of fish

As of 2010, there are 27 health advisories that have been issued by the VDH due to mercury contamination of fish throughout the state.

Mercury is released into the environment by both natural sources and pollution. Biological processes transform mercury in the water into more toxic methylmercury. Fish absorb methylmercury directly from water, sediment and from eating smaller aquatic organisms that contain methylmercury.

Prior to 2001, VDH followed guidelines developed by the FDA that considered methylmercury levels higher than 1.0 ppm in exceedence of safety guidelines. In 2001, the VDH began to use a concentration of 0.5 ppm methylmercury in fish tissue as the guideline for issuing a fish consumption advisory statewide. The revised fish consumption guidelines for mercury contamination were based on an extensive review of literature by the National Academy of Sciences which indicated that lowering the amount of mercury recommended for fish consumption would provide more protection for the public. This lower concentration of 0.5 ppm is also based on assuming a consumption rate of two eight-ounce meals per month as an exposure rate for triggering a fish consumption advisory. This new, lower concentration of concern for mercury used by the VDH has increased the number of watersheds subject to fish consumption advisories due to mercury contamination. The watersheds covered by fish consumption advisories due to mercury contamination are described below.

- *Mercury in the North Fork Holston River*

Eighty miles of the North Fork Holston River in southwestern Virginia from Saltville to the Virginia-Tennessee state line were contaminated with mercury by releases from the Olin manufacturing operation in Saltville. Although the chemical plant closed in 1972, mercury levels in fish in this section of the river remain elevated above levels seen upstream and the consumption of fish from this area is prohibited. Since 1974, only catch and release fishing has been allowed. Several species of fish in these waters show mercury concentrations higher than the VDH's level of concern of 0.5 ppm. This health restriction affects the following watersheds VAS-O13, VAS-O12, VAS-O11, and VAS-O10. DEQ has completed a TMDL for mercury in the North Fork Holston River, and remediation of the industrial releases is ongoing.

- *Mercury in the South River, South Fork Shenandoah River, North Fork Shenandoah River and Shenandoah River*

Mercury was released by E. I. DuPont de Nemours and Company, a synthetic fibers plant in Waynesboro, into the South River and South Fork Shenandoah River from 1929 to 1950. The contamination was discovered in 1977 and was found to have contaminated more than 100 river miles from the plant to the Page/Warren county line. These areas remain under health advisories for fish consumption due to mercury contamination. The advisory was updated in 2001 as follows. For the South River, the VDH recommends that no fish, other than stocked trout, should be eaten from the footbridge at the DuPont plant in Waynesboro downstream to the confluence with the North River at Port Republic. For the South Fork Shenandoah River, the VDH recommends that no more than two eight-ounce meals per month of fish from these waters be consumed from Port Republic to the Riverton dam on the North Fork Shenandoah River and downstream in the Shenandoah River to the Warren Power dam just north of Front Royal. A concurrent advisory issued in 2004 due to PCB contamination of part of the segment recommends no consumption of channel catfish, carp or sucker species. Several species of fish in these waters show mercury concentrations higher than the VDH's level of concern of 0.5 ppm. This health advisory is located in all or a portion of watersheds, VAV-B40, VAV-B38, VAV-B37, VAV-B35, VAV-B33, and VAV-B32. DEQ has completed TMDLs for mercury in the affected water bodies, and remediation of the industrial releases is ongoing.

- *Mercury in swamp waters, lakes, impoundments, and other waters*

In October 2003, the VDH established fish consumption advisories due to elevated mercury levels detected in fish tissue in top level predator fish species for three swamps or "blackwater" rivers where there are no known significant anthropogenic sources of mercury contamination. Subsequent monitoring in other swamp influenced bodies of water has resulted in additional fish consumption advisories in other watersheds since 2003. These water bodies share similar natural, chemical and physical characteristics of low dissolved oxygen, low pH, high organic content and still or slow moving current which promote the natural methylation of mercury into the highly bioaccumulative compound methylmercury. In recent years, a better understanding has developed that waterbodies with these environmental conditions are likely to promote the conversion of elemental mercury into the toxic form methylmercury which is more easily bioaccumulated into fish tissue in these waters. Increased natural production of methylmercury in these waters enhances the possibility that the mercury content of fish will increase especially in upper level predators. Similar elevated levels of mercury in piscivorous species of fish have been noted in similar habitats in the southeastern United States as well as lakes, bogs and wetlands in New England, Wisconsin and Minnesota. In many of these areas, there are no known sources of mercury. Deposition of airborne mercury has been identified as a possible source of the mercury to the swamp waters. This is considered a possibility in swamp waters in Virginia also. DEQ is investigating air deposition of mercury and other potential sources of mercury to these water bodies. DEQ has initiated additional monitoring of fish in these areas to better understand the extent of the elevated mercury concentrations.

Fish Consumption Advisories issued October 29, 2003 due to Mercury are listed below:

- *Dragon Run Swamp and Piankatank River watershed*

The entire length of Dragon Run Swamp from Route 620 near the headwaters of Dragon Run downstream to a segment of the Piankatank River near the Route 606 boat landing is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of largemouth bass. The original advisory issued in 2003 was updated in 2005 to cover the entire Dragon Run Swamp watershed. DEQ is conducting an assessment of the watershed looking for sources of mercury to the watershed. The affected watersheds are VAP-C02R, VAP-C02E and VAP-C03E.

- *Great Dismal Swamp Canal watershed*

The segment of the Great Dismal Swamp Canal from Deep Creek Lock south to the Virginia-North Carolina state line, including Lake Drummond and the feeder ditch to Lake Drummond, is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of bowfin or chain pickerel. The inclusion of Lake Drummond in 2005 was an update of the previous advisory issued in 2003 for this area. The affected watershed is VAT-K39.

- *Blackwater River watershed*

The entire Blackwater River watershed from its headwaters near Petersburg downstream to the Virginia - North Carolina border including all its tributaries is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of largemouth bass, redear sunfish bowfin, white catfish, redhorse sucker, longnose gar and chain pickerel. The original advisory issued in 2003 affected largemouth bass and redear sunfish from the state line up to Rt. 460. The advisory was updated to include bowfin, white catfish, redhorse sucker and longnose gar and the segment was extended upstream to Rt. 31 in 2005 The latest update in 2007 expanded the segment to include the entire watershed and chain pickerel species. The affected watersheds are VAP-K31 VAP-K32 VAP-K34 VAT-K34, VAT-K33 and VAT-K36.

Fish Consumption Advisories issued September 30, 2004 due to Mercury are listed below:

- *Lake Trashmore*

Lake Trashmore (entire lake) in Virginia Beach is covered by an advisory. This advisory recommends eating no more than two eight-ounce meals per month of largemouth bass due to elevated levels of mercury and carp due to elevated levels of PCBs.

- *Lake Whitehurst*

Lake Whitehurst (entire lake) in Norfolk and Virginia Beach is covered by an advisory. The initial advisory recommended that carp should not be eaten due to elevated levels of mercury and PCBs and that no more than two eight-ounce meals per month of yellow perch should be eaten due to elevated levels of PCBs. The advisory for Lake Whitehurst (entire lake) has been expanded to include the Little Creek Reservoir arm of the lake in 2009. This updated advisory recommends that no more than two eight-ounce meals per month of carp or gizzard shad species should be consumed due to elevated levels of mercury and PCBs. Yellow perch is no longer affected by this advisory.

- *Lake Gordonsville*

Lake Gordonsville (entire lake) in Louisa County is covered by an advisory. This advisory recommends eating no more than two eight-ounce meals per month of largemouth bass.

- *Pamunkey River*

An advisory was issued for the segment of the Pamunkey River from the Route 615 bridge to the confluence with Jacks Creek. This advisory recommended eating no more than two eight-ounce meals

per month of blue catfish. In 2009, the segment was expanded from Route 615 to the confluence with the Mattaponi River near West Point. A concurrent advisory issued in 2009 due to PCB contamination of the segment recommends eating no more than two eight-ounce meals per month of gizzard shad as well. The expanded segment from Route 615 to the confluence with the Mattaponi River near West Point is now covered by both mercury and PCB advisories.

- *Mattaponi River*

An advisory was issued for the segment of the Mattaponi River from the Route 628 bridge downstream to Melrose Landing. This advisory recommended eating no more than two eight-ounce meals per month of largemouth bass. In 2009, the segment was expanded from Route 628 to the confluence with the Pamunkey River near West Point. There had been an existing advisory due to PCB contamination for part of the segment of the Mattaponi River from the confluence with Herring Creek downstream to the confluence with Aylett Creek since 2004 that recommended eating no more than two eight-ounce meals per month of striped bass, white perch or gizzard shad which was also updated in 2009. The expanded segment from Route 628 to the confluence with the Pamunkey River near West Point is now covered by both mercury and PCB advisories.

- *Herring Creek*

The segment of the Herring Creek in King William County from the Route 628 bridge to the confluence with the Mattaponi River is covered by an advisory. This advisory recommends eating no more than two eight-ounce meals per month of bluegill sunfish or yellow bullhead catfish.

Fish Consumption Advisories issued July 27, 2005 due to Mercury are listed below:

All the three fish consumption advisories listed below that were modifications to existing advisories issued in 2003 (see description under the 2003 fish consumption advisories).

- *Dragon Run Swamp and Piankatank River watershed*

The health advisory for the Dragon Run Swamp (entire length) from the Route 620 downstream to a segment of the Piankatank River near Deep Point Boat Landing at Route 606 across from Piankatank Shores was updated. The extension from the headwaters to Deep Point Boat Landing is an update of the previous advisory for this area.

- *Great Dismal Swamp Canal watershed*

The health advisory for the Great Dismal Swamp Canal from the Deep Creek Locks south to the Virginia/North Carolina state line including Lake Drummond and Feeder Ditch was updated. The inclusion of Lake Drummond is an update of the previous advisory for this area.

- *Blackwater River watershed*

The health advisory for the Blackwater River from Rt. 31 near Dendron downstream to the Virginia/North Carolina state line was updated. The extension of the Blackwater River from Rt. 460 to Rt. 31 is an update of the previous advisory for this area.

Fish Consumption Advisories issued July 20, 2006 due to Mercury are listed below:

- *Harrison Lake*

Harrison Lake (entire lake) in Charles City County is covered by an advisory. This advisory recommends that no more than two eight-ounce meals of redear sunfish, largemouth bass, chain

pickerel, or bowfin should be consumed per month.

- *Chickahominy Lake*

Chickahominy Lake (entire lake) in Charles City and New Kent counties is covered by an advisory. This advisory recommends that no more than two eight-ounce meals of largemouth bass, chain pickerel, or bowfin should be consumed per month.

Fish Consumption Advisories issued August 31, 2007 due to Mercury are listed below:

- *Blackwater River watershed*

The health advisory for the Blackwater River from the Virginia-North Carolina state line upstream to its headwaters near Petersburg including all its tributaries was updated (see description under the 2003 fish consumption advisories).

- *Nottoway River watershed*

The segment of the Nottoway River from the confluence with the Blackwater River at the Virginia-North Carolina state line upstream to Route 619 near Purdy including its tributary Assamoosick Swamp is covered by an advisory. This main stem Nottoway River segment is ~92 miles. The advisory recommends that no more than two eight-ounce meals per month of largemouth bass, smallmouth bass, bowfin, redhorse sucker species, longnose gar, channel catfish, chain pickerel, or sunfish species should be consumed.

- *Motts Run Reservoir*

Motts Run Reservoir (entire reservoir) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

- *Chandler's Mill Pond*

Chandler's Mill Pond (entire pond) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

- *Roanoke River watershed (Staunton River)*

The segment of the Roanoke (Staunton) River from below Leesville Dam downstream to the confluence with the Dan River including its tributary Cub Creek up to Rough Creek Road (Route 695) near Rough Creek is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of striped bass or white bass species should be consumed. There has been an existing advisory due to PCBs for various species in this segment since 1999.

- *Kerr Reservoir watershed*

Kerr Reservoir within the state of Virginia from the confluence of Dan River and Roanoke River to the John H. Kerr Dam including its tributaries Eastland Creek and Nutbush Creek (within the state of Virginia) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of striped bass, white bass or largemouth bass species should be consumed. There has been an existing advisory due to PCBs for various species in this segment since 2004.

- *Dan River watershed*

The segment of the Dan River within the state of Virginia from the Brantley Steam Plant Dam in Danville downstream to the confluence with the Roanoke River on the John H. Kerr Reservoir, including

its tributaries Hyco River up to the Route 738 bridge and Banister River up to the Banister Dam, is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of striped bass or white bass species should be consumed. There has been an existing advisory due to PCBs for various species in this segment since 1999.

Fish Consumption Advisories issued September 16, 2008 due to Mercury are listed below:

- *Lovills Creek Lake watershed*

Lovills Creek Lake (entire lake) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

- *Dan River watershed*

The segment of the Dan River within the state of Virginia from the Brantley Steam Plant Dam in Danville downstream to the confluence with the Roanoke River on John. H. Kerr Reservoir, including its tributaries Hyco River up to the Rt. 738 bridge and Banister River up to the Banister Dam is covered by an advisory. This advisory was updated and recommends that in addition to striped bass and white bass no more than two eight-ounce meals per month of longnose gar, largemouth bass, flathead catfish or blue catfish species should be consumed.

- *Nottoway River watershed*

The segment of the Nottoway River from the confluence with the Blackwater River at the Virginia-North Carolina state line upstream to State Route 619 near Purdy including its tributary Assamoosick Swamp, Three Creek up to I-95, Rowanty Creek and its tributaries Hatcher Run up to I-85 and Arthur Swamp up to I-85 is covered by an advisory. The previous advisory was updated with the addition of Three Creek up to I-95, Rowanty Creek and its tributaries Hatcher Run up to I-85 and Arthur Swamp up to I-85.

- *Emporia Reservoir watershed*

Emporia Reservoir on the Meherrin River (entire reservoir) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

- *Meherrin River watershed*

The segment of the Meherrin River below Emporia Reservoir Dam to the Virginia-North Carolina state line including its tributaries Fontaine Creek up to I-95 bridge crossing and Mill Swamp up to I-95 bridge crossing is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass or bowfin species should be consumed. There has been an existing advisory due to PCB contamination of gizzard shad for a segment of the Meherrin River from Emporia Dam downstream to the Route 730 bridge crossing since 2004.

- *Big Cherry Reservoir watershed*

Big Cherry Reservoir (entire reservoir) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

- *Lake Witten watershed*

Lake Witten (entire lake) is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of largemouth bass species should be consumed.

Fish Consumption Advisories issued October 7, 2009 due to Mercury are listed below:

- *Reedy Creek watershed*

The segment of Reedy Creek from Rt. 301 downstream to the confluence with the Mattaponi River is covered by an advisory. This advisory recommends eating no more than two eight-ounce meals per month of bluegill sunfish or yellow bullhead catfish.

- *Pamunkey River watershed*

The segment of the Pamunkey River from Nelson Bridge Road (Route 615 bridge) downstream to the confluence with the Mattaponi River near West Point is covered by an advisory. The previous segment was expanded to cover additional stretch of the river from Jacks Creek to West Point. The expanded segment is covered by both mercury and PCB advisories.

- *Mattaponi River watershed*

The segment of the Mattaponi River from Rt. 628 near gaging station downstream to the confluence with the Pamunkey River near West Point is covered by an advisory. The previous segment was expanded to cover additional stretch of the river from Melrose Landing to West Point. The expanded segment is covered by both mercury and PCB advisories.

- *Lake Whitehurst watershed including Little Creek Reservoir arm*

The advisory for Lake Whitehurst (entire lake) has been expanded to include the Little Creek Reservoir arm of the lake. This updated advisory recommends that no more than two eight-ounce meals per month of carp or gizzard shad species should be consumed. The expanded segment is covered by both mercury and PCB advisories.

Fish Consumption Advisories issued November 18, 2009 due to Mercury are listed below:

- *Lake Gaston watershed*

Lake Gaston within the state of Virginia from the confluence of John H. Kerr Dam to the state line is covered by an advisory including any tributary arms of the lake. This advisory recommends that no more than two eight-ounce meals per month of walleye should be consumed.

Fish consumption advisories due to polychlorinated biphenyls (PCBs) contamination

As of 2010, there are 43 health advisories that have been issued by the VDH due to contamination of fish by PCBs throughout the state. Historically, Virginia has steadily lowered the levels of PCBs considered acceptable in fish. Prior to 1980, VDH followed guidelines developed by the FDA that considered PCB levels higher than 5,000 parts per billion (ppb) in exceedence of safety guidelines. In 1984, the FDA reduced the level to 2,000 ppb. In 1998, VDH developed its own fish consumption advisory guidelines and set its levels of concern for PCBs in fish to no more than 600 ppb. This limit was lowered to 50 ppb in 2004. The latest guidelines announced by VDH in 2012 increased that level to 100 ppb. The change reflects VDH's adoption of the updated exposure factors (such as average body weight) and human behavior-related assumptions recommended by EPA. This change does not affect previously issued consumption advisories or current impairment listings. The watersheds covered by fish consumption advisories due to PCB contamination are described below.

- *South Fork Shenandoah River, North Fork Shenandoah River and Shenandoah River*

In 1989, the VDH issued a public health advisory warning against the consumption of fish taken from the South Fork Shenandoah River near Front Royal because of PCBs contamination of fish in the area. The advisory extended from the Route 619 bridge downstream to the Shenandoah River. It continued from the North Fork Shenandoah River at its confluence with Passage Creek downstream to the Shenandoah River; and from the Shenandoah River from the confluence of the North and South Fork Shenandoah Rivers to the Virginia-West Virginia state border. This segment covered approximately 45 stream miles. This advisory was issued after DEQ monitoring revealed PCB levels in fish tissue samples above the 2.0 ppm FDA action level. The advisory stated that fish caught in these waters should not be consumed. The source of this contamination has been identified as Avtex Fibers Front Royal Inc. This plant closed in 1989 following revocation of their VPDES permit. The advisory was updated in 2004 and the segment on the North Fork was modified to exclude the zone above the Riverton dam. The advisory recommended no consumption of channel catfish, carp or sucker species and that no more than two eight-ounce meals per month of smallmouth bass, largemouth bass, rock bass, or sunfish species should be consumed. This health advisory is located in the watersheds: VAV-B58, VAV-B57, VAV-B55, VAV-B51 and VAV-B41. DEQ has completed a TMDL for PCBs in the affected water bodies, and remediation of the industrial releases is ongoing.

- *Main stem Roanoke River watershed (Staunton River)*

In July 1998, a health advisory for fish consumption was issued for a 50-mile stretch of the Roanoke River running through Campbell, Charlotte, Halifax and Pittsylvania counties. PCBs had been detected at elevated levels in fish tissues of striped bass, white bass and carp. The advisory area extended from Seneca Creek at Route 704 near Long Island downstream to the point where a pipeline intersects Route 803 and where Route 633 in Charlotte County crosses the Roanoke River (approximately 5.4 river miles below the Rt. 360 bridge). In December 1999, the VDH expanded this fish advisory to include 29 additional miles upstream including Altavista to the Leesville Dam. In 2004, this advisory was extended to include the Roanoke River from the Leesville Dam downstream to the confluence with the Dan River. The advisory for this section of the Roanoke River recommends no consumption of carp and flathead catfish greater than 32 inches and no more than two eight-ounce meals per month of flathead catfish less than 32 inches, channel catfish, gizzard shad, golden redhorse sucker, redhorse sucker, quillback carpsucker, bluehead chub, white perch, walleye, striped bass, white bass, largemouth bass, smallmouth bass, spotted bass, rock bass or sunfish species should be consumed. The advisory has been updated in 2007 to include a portion of Cub Creek up to Rough Creek Road (State Route 695) near Rough Creek and recommends no more than two eight-ounce meals per month of blue catfish in the entire segment. A potential contributing source of the contamination has been identified but other sources are suspected. The affected watersheds are VAW-L19, VAW-L30, VAW-L31, VAP-L36, VAP-L38, VAP-L40, VAP-L75 and VAP-L80. In 2007, a mercury advisory was issued for striped bass and white bass for the segment. DEQ has completed a TMDL for PCBs in the affected water bodies, and is pursuing implementation strategies through permitting and collaboration with DEQ's clean-up programs.

- *Fresh tidal embayments of the Potomac River*

In April 1999, a health advisory for fish consumption was issued for a 33-mile stretch of the Potomac River from the Woodrow Wilson Bridge to Bent Point at the mouth of Aquia Creek due to contamination of fish by PCBs in the embayments of the Potomac River. The advisory states "channel catfish larger than 18 inches caught in the tidal areas in several tributaries flowing into the Potomac River near Quantico, VA may pose a potential public health risk". The VDH issued this advisory in collaboration with Maryland, since most of this area of the Potomac River is in Maryland. The advisory was modified in 2003 and 2004 to include other fish species. In December 2004, the VDH modified the fish consumption advisory for the tidal portion of the following tributaries and embayments to the Potomac River between the I-395 bridge in Arlington downstream to the Rt. 301 bridge: Four Mile Run, Hunting Creek, Little Hunting Creek, Pohick Creek, Accotink Creek, Occoquan River, Neabsco Creek, Powell Creek, Quantico Creek, Chopawamsic Creek, Aquia Creek, and Potomac Creek. The advisory recommends no consumption of carp or channel catfish greater than 18 inches and limiting consumption to no more than two eight-ounce meals per month of channel catfish less than 18 inches, American eel, bullhead catfish,

largemouth bass, anadromous striped bass, sunfish species, smallmouth bass, white catfish, white perch, gizzard shad, or yellow perch. This advisory was updated in 2009 to caution that American eel should not be eaten from these waters. DEQ has completed a TMDL for PCBs in the affected water bodies, and is pursuing implementation strategies through permitting and collaboration with DEQ's clean-up programs.

- *Levisa Fork*

In July 1999, a health advisory for fish consumption was issued for a 12-mile section of the Levisa Fork from Grundy downstream to the Virginia-Kentucky state line. This advisory recommends that no fish of any kind be eaten from that section of the Levisa Fork. The advisory was modified in 2003 and 2004. The affected watershed is VAS-Q08. DEQ has completed a TMDL for PCBs in the affected water bodies, and is pursuing implementation strategies through permitting and collaboration with DEQ's clean-up programs.

- *Dan River watershed*

In December 1999, a health advisory for fish consumption was issued for a 42 mile stretch of the Dan River from Kerr Reservoir at Staunton River State Park to southwestern Halifax County where the river crosses into North Carolina, north of Virginia Route 62. This fish consumption advisory was modified in December 2004 to cover the river within Virginia from the Brantley Steam Plant Dam in Danville and to include the following tributaries: the Hyco River up to the Rt. 738 bridge and the Banister River up to the Banister Dam. The advisory cautions people to not eat any flathead catfish greater than 32 inches and to eat no more than two eight-ounce meals per month of flathead catfish less than 32 inches, channel catfish, blue catfish, carp, redhorse sucker, striped bass, white bass, white perch or walleye taken from the advisory area. The affected watersheds are VAW-L60, VAP-L62, VAP-L64 and VAP-L73. In 2007, a mercury advisory was issued for striped bass and white bass for the segment. Longnose gar, largemouth bass, flathead catfish or blue catfish were added to the list of species affected by elevated mercury in 2008.

- *Bluestone River*

In August 2001, the VDH issued (and modified in December 2004) a health advisory for fish consumption for a section of the Bluestone River from the Rt. 460 bridge crossing south of Bluefield downstream to the Virginia-West Virginia state line near the town of Yards in Tazewell County. The advisory recommends not eating any carp and to limit consumption to no more than two eight-ounce meals per month of white sucker, rock bass or largemouth bass from this section of the Bluestone River. The affected watersheds are VAS-N36 and VAS-N37.

- *New River*

In August 2001, the VDH issued (and modified in December 2004) a health advisory for fish consumption for a section of the New River from the Claytor Lake Dam downstream to the Virginia/West Virginia state line near the town of Glen Lyn. The advisory recommends not eating any carp and limiting consumption of flathead or channel catfish to no more than two eight-ounce meals per month.

- *Tidal Lower James River watershed*

In July 2002, the VDH issued a health advisory for fish consumption for a section of the James River from the Interstate 95 bridge in Richmond downstream to the Hampton Roads bridge and the tidal portions of the following tributaries: Appomattox River up to the Lake Chesdin Dam, Bailey Creek up to Rt. 630, Bailey Bay, Chickahominy River up to Walkers Dam, Skiffes Creek up to the Skiffes Creek Dam, Pagan River and Jones Creek, Chuckatuck Creek, Nansemond River, Bennett Creek, Star Creek, Hampton River, Willoughby Bay and the Elizabeth River system (Western Branch, Eastern Branch, Southern Branch and the Lafayette River), and tidal tributaries St. Julian Creek, Deep Creek and Broad Creek. The advisory was modified in 2004 and recommends not eating any gizzard shad, carp or blue

catfish greater than 32 inches and limiting consumption to no more than two eight-ounce meals per month of blue catfish less than 32 inches, channel catfish, white catfish, largemouth bass, white perch, bluegill sunfish, American eel, flathead catfish, quillback carpsucker, smallmouth bass, creek chub, yellow bullhead catfish, anadromous striped bass, bluefish, croaker and spot. In 2006, the existing advisory was updated to include additional species, with a consumption recommendation of no more than two eight-ounce meals per month of hickory shad, blueback herring and flathead catfish less than 32 inches. Additionally, flathead catfish greater than or equal to 32 inches should not be eaten. Poythress Run, a small tributary in Hopewell, was added to the advisory for the lower James River. DEQ is conducting additional investigations in this area to better determine the extent of the concern and to try to find the source of the contamination. The affected watersheds are VAP-G01E through VAP-G04E, VAP-G08E, VAP-J15E, VAT-G10E, VAT-G11E, VAT-G13E and VAT-G15E.

- *Smith Mountain Lake watershed (Roanoke River)*

In October 2003, the VDH issued a fish consumption advisory for a section of the Roanoke River from the Niagara Dam downstream to a point in the Smith Mountain Lake, approximately 2.5 miles downstream of the Rt. 634 bridge. DEQ fish tissue monitoring data from 2002 showed that flathead catfish collected from the Roanoke River near Hardy contained total PCBs at levels that exceeded the VDH's level of concern. This advisory zone was modified in 2004 and expanded to the Smith Mountain Lake Dam including the Blackwater River arm up to the Rt. 122 bridge. This fish consumption advisory recommends not eating any flathead catfish greater than 32 inches and eating no more than one eight-ounce meal per month of flathead catfish less than 32 inches, striped bass, largemouth bass, carp, redhorse sucker, or gizzard shad from this advisory area. The advisory was updated in 2005 and recommended that in addition the species listed above no more than two eight-ounce meals per month of channel catfish should be consumed in this segment. The affected watersheds are VAW-L07 and VAW-L12.

- *Knox Creek watershed*

In May 2003, the VDH issued (and modified in June 2004 and updated in December 2004) a health advisory for fish consumption for a section of Knox Creek from the Virginia-Kentucky state line upstream to its headwaters. The advisory recommends not eating any smallmouth bass, rock bass, channel catfish, creek chub, golden redhorse sucker, northern hogsucker or redhorse sucker and eating no more than two eight-ounce meals per month of any other fish species taken from the advisory area. DEQ intends to conduct additional investigations in this area to better determine the extent of the concern and to try to find the source of the contamination. The affected watershed is VAS-Q03.

- *Beaver Creek watershed*

In May 2003, the VDH issued (and modified December 2004) a health advisory for fish consumption for a section of Beaver Creek from the Beaver Creek Lake Dam downstream to the Virginia-Tennessee state line in Bristol. The advisory recommends not eating any carp, largemouth bass or smallmouth bass and eating no more than one eight-ounce meal per month of any other fish taken from the advisory area. DEQ intends to conduct additional investigations in this area to better determine the extent of the concern and to try to find the source of the contamination. The affected watershed is VAS-O07.

- *Lake Anna watershed (York River)*

In June 2004, the VDH issued a fish consumption advisory for Lake Anna including its tributaries Terry's Run, Goldmine Creek and Contrary Creek. The advisory was modified in December 2004 to recommend eating no more than two eight-ounce meals per month of carp, largemouth bass, striped bass, white catfish, channel catfish or bluegill sunfish caught in the watershed. This advisory was updated in 2007 to further recommend not eating any gizzard shad and no more than two eight-ounce meals per month of white perch.

Fish Consumption Advisories issued in December 13, 2004 due to new PCBs guidelines are listed below:

In December 2004, following the lowering of the amount of PCBs necessary to trigger a fish consumption advisory, a number of new health advisories were issued throughout the state. The advisories that were issued are described below.

- *Lewis Creek*

The segment of Lewis Creek from Rt. 252 south of Staunton downstream to the confluence of the Middle River is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of bluehead chub or white sucker.

- *Upper Potomac River watershed*

The following tributaries to the Potomac River between the Virginia-Maryland state line near Rt. 340 downstream to the I-395 bridge in Arlington, Goose Creek up to the Dulles Greenway Road bridge, Broad Run up to Rt. 625, Difficult Run up to Rt. 7, and Pimmit Run up to Rt. 309 are covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of American eel from these waters.

- *Tidal tributaries of the Lower Potomac River*

The tidal portion of the following tributaries to the Potomac River between the Rt. 301 bridge downstream to the mouth of the river near Smith Point: Upper Machodoc Creek, Monroe Creek and Coan River are covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of gizzard shad, white perch or channel catfish from these waters.

- *Bull Run*

Bull Run in Fairfax County, Manassas Park City and Prince William County near Manassas Park from the I-66 bridge downstream to the Route 612 (Yates Ford Road) bridge is covered by an advisory. The previous advisory issued in 2004 recommended that no more than two eight-ounce meals per month of channel catfish should be consumed. The advisory was updated in 2005 to also recommend that no more than two eight-ounce meals per month of carp should be consumed.

- *Rappahannock River watershed*

The segment of the Rappahannock River from the I-95 bridge downstream to the mouth of the river including the tributaries Hazel Run up to the I-95 bridge and Claiborne Run up to the Rt. 1 bridge is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of American eel, blue catfish, carp, channel catfish, croaker, gizzard shad or striped bass caught in these waters.

- *Mountain Run*

The segment of Mountain Run from Rt. 15/29 bridge near Culpepper to the confluence with the Rappahannock River is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of American eel.

- *York River watershed*

The segment of the York River from West Point down to the mouth as well as the tidal portion of the following tributaries: King Creek, Queen Creek and Wormley Creek are covered by an advisory. The

advisory recommends eating no more than two eight-ounce meals per month of croaker, spot or gizzard shad caught in these waters.

- *Mattaponi River*

An advisory was issued for the segment of the Mattaponi River from the confluence with Herring Creek downstream to the confluence with Aylett Creek. The advisory recommended eating no more than two eight-ounce meals per month of anadromous striped bass, white perch or gizzard shad caught in this segment of the watershed. The segment was expanded in 2009 to cover additional stretch of the river from Rt. 628 near gaging station downstream to the confluence with the Pamunkey River near West Point. The expanded segment is covered by both mercury and PCB advisories.

- *Maury River*

The segment of the Maury River from Buena Vista at Rt. 60 to the confluence with the James River is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of redbreast sunfish, rock bass or yellow bullhead catfish caught in this section of the river. The advisory was updated in 2006 and also recommended that no more than two eight-ounce meals per month of carp should be eaten from this segment.

- *Middle James River watershed*

The segment of the James River from Big Island Dam (below the Blue Ridge Parkway) downstream to the I-95 bridge in Richmond including its tributaries: Hardware River up to the Rt. 6 bridge and Slate River up to Route 676 is covered by an advisory. The advisory recommends limiting consumption to no more than two eight-ounce meals per month of gizzard shad, carp, American eel, quillback carpsucker or flathead catfish caught in this section of the river.

- *Chesapeake Bay and Small Coastal Bays Basin*

The Chesapeake Bay and its small coastal tributaries are covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of anadromous striped bass caught in these waters.

- *Lake Trashmore*

Lake Trashmore (entire lake) in Virginia Beach is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of carp. Mercury advisory exists for largemouth bass for the segment as well.

- *Lake Whitehurst*

An advisory was issued for Lake Whitehurst (entire lake) in Norfolk. The advisory initially recommended that carp should not be eaten due to elevated levels of PCBs and mercury and that no more than two eight-ounce meals per month of yellow perch should be eaten due to elevated levels of PCBs. In 2009, the advisory for Lake Whitehurst (entire lake) was expanded to include the Little Creek Reservoir arm of the lake. This updated advisory recommends that no more than two eight-ounce meals per month of carp or gizzard shad species should be consumed. The expanded segment is covered by both mercury and PCB advisories. Yellow perch is no longer affected by this advisory.

- *Eastern Branch Lynnhaven River*

Eastern Branch of Lynnhaven River in Virginia Beach is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of gizzard shad.

- *Little Creek*

Little Creek in Norfolk near the Naval Reservation Little Creek Amphibious Base is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of gizzard shad, spot or croaker.

- *Tabb Creek*

An advisory was issued for Tabb Creek near Langley Air Force Base in Poquoson City. The advisory initially recommended eating no more than two eight-ounce meals per month of croaker or gizzard shad. In 2009, the advisory was updated to recommend that gizzard shad should not be eaten and that no more than two eight-ounce meals per month of croaker, striped bass, oyster or blue crab from this creek be eaten.

- *Mobjack Bay*

Mobjack Bay and its tributaries: East River, North River and Ware River in Mathews and Gloucester counties are covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of gizzard shad.

- *Meherrin River*

The segment of the Meherrin River from Emporia Dam downstream to Route 730 bridge crossing is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of gizzard shad. In 2008, a mercury advisory was issued for largemouth bass and bowfin for the segment as well.

- *Upper Roanoke River watershed*

The upper portion of the Roanoke River from the confluence of the South and North Forks of the Roanoke River at Lafayette downstream to the Niagara Dam including its tributaries Peters Creek up to the Rt. 460 bridge and Tinker Creek up to the confluence with Deer Branch Creek near Rt. 115 is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of carp, redhorse sucker, bluehead chub, largemouth bass, smallmouth bass, rock bass or redbreast sunfish.

- *Kerr Reservoir watershed (Roanoke River)*

Kerr Reservoir within the state of Virginia from the confluence of the Dan River and Roanoke River to the John H. Kerr Dam including its tributaries Eastland Creek and Nutbush Creek is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of carp, redhorse sucker, largemouth bass, smallmouth bass, white bass, striped bass, white perch, walleye, channel catfish or flathead catfish. In 2007, a mercury advisory was issued for striped bass, white bass and largemouth bass for the segment.

- *New River*

The segment of the New River from I-77 downstream to the Claytor Lake Dam including Peak Creek up to the confluence with North Fork Peak Creek (Track Fork) and Reed Creek up to the confluence with Miller Creek near Rt.121 is covered by an advisory. The advisory recommends not eating more than two eight-ounce meals per month of carp or smallmouth bass.

- *Upper Levisa Fork watershed*

The segment of the upper Levisa Fork from the confluence of Slate Creek upstream to the

confluence with Contrary Creek including the tributary Garden Creek up to the confluence of the Right Fork of Garden Creek is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of all fish species in the watershed.

- *Guest River watershed*

The segment of Guest River from Rt. 23 near Esserville downstream to the confluence with the Clinch River, including the tributary Bear Creek up to the confluence with Yellow Creek is covered by an advisory. The advisory recommends eating no more than two eight-ounce meals per month of carp, river chub or stoneroller from the watershed.

- *Stock Creek*

The segment of Stock Creek from Route 650 bridge above Natural Tunnel downstream to the confluence with Clinch River near Clinchport is covered by an advisory. The advisory recommends not eating more than two eight-ounce meals per month of brown trout, rainbow trout, or white sucker caught in this segment of the watershed.

- *Wolf Creek*

The segment of Wolf Creek from Route 670 near Abington downstream to Rt. 75 near Green Spring is covered by an advisory. The advisory recommends not eating more than two eight-ounce meals per month of carp or northern hogsucker caught in this segment of the watershed

- *North Fork Holston River*

A segment of the North Fork Holston River between Rt. 91 near Saltville downstream to Rt. 80 is covered by an advisory. PCBs were detected in fish above the guidelines recommended by the VDH for safe consumption of more than two eight-ounce meals per month. However, this segment of the river has an existing ban or prohibition on taking any fish for consumption in the North Fork Holston River due to mercury contamination. Only catch and release of these fish is permissible.

Fish Consumption Advisories issued in July 27, 2005 due to PCBs are listed below:

- *Indian Run*

Indian Run (entire Run) in Fairfax County near Annandale downstream from State Route 236 approximately three miles to Back Lick Run is covered by an advisory. The advisory recommends that no more than two eight-ounce meals per month of creek chub should be consumed.

- *Bull Run*

The health advisory for Bull Run in Fairfax County, Manassas Park City and Prince William County near Manassas Park from the I-66 bridge downstream to the Route 612 (Yates Ford Road) bridge has been updated. The previous advisory recommended that no more than two eight-ounce meals per month of channel catfish should be consumed. The advisory was updated in 2005 to also recommend that no more than two eight-ounce meals per month of carp should be consumed.

- *Smith Mountain Lake watershed (Roanoke River)*

The health advisory for Roanoke River/Smith Mountain Lake in Roanoke County, Franklin County, Bedford County and Pittsylvania County from below the Niagara Dam downstream to Smith Mountain Dam, including the Blackwater River to the Rt. 122 bridge has been updated. The advisory has been updated to also recommend that no more than two eight-ounce meals per month of channel catfish should be consumed.

- *Beaver Creek watershed*

The health advisory for Beaver Creek in Washington County and Bristol City from Beaver Creek Dam downstream to the Virginia-Tennessee state line within the City of Bristol has been updated. The affected segment was expanded to include, Little Creek, a tributary and modified to also recommend that smallmouth bass should not be eaten and no more than two eight-ounce meals per month of any other species should be consumed.

- *Knox Creek watershed*

The health advisory for Knox Creek in Buchanan County from the Virginia-Kentucky state line upstream to its headwaters near the Virginia-West Virginia state line including its tributaries has been updated. The advisory was modified to also recommend that channel catfish, redhorse sucker and creek chub not be consumed.

Fish Consumption Advisories issued in October 10, 2006 due to PCBs are listed below:

- *Maury River*

The health advisory for the segment of the Maury River from Buena Vista at Rt. 60 to where it meets the James River has been updated. VDH recommends that no more than two eight-ounce meals per month of carp should be consumed.

- *Tidal Lower James River watershed*

The health advisory for the segment of the James River from the I-95 James River bridge in Richmond downstream to the Hampton Roads Bridge Tunnel has been updated. VDH included additional species with a consumption recommendation of no more than two eight-ounce meals per month of hickory shad, blueback herring and flathead catfish less than 32 inches. Additionally, flathead catfish greater than or equal to 32 inches should not be eaten. Poythress Run, a small tributary in Hopewell, was added to the advisory for the lower James River.

Fish Consumption Advisories issued in August 31, 2007 due to PCBs are listed below:

- *Main stem Roanoke River watershed (Staunton River)*

The health advisory for the segment of the Roanoke (Staunton) River from below Leesville Dam downstream to the confluence of the Dan River has been updated to include its tributary Cub Creek up to Rough Creek Road (Route 695) near Rough Creek. A concurrent mercury advisory exists for various species in the segment as well.

- *Lake Anna watershed (York River)*

The health advisory for Lake Anna including its tributaries Terry's Run, Goldmine Creek and Contrary Creek has been updated to further recommend not eating any gizzard shad and no more than two eight-ounce meals per month of white perch.

Fish Consumption Advisories issued in September 16, 2008 due to PCBs are listed below:

- *Dan River watershed*

The advisory for the segment of the Dan River within the state of Virginia from the Brantley Steam Plant Dam in Danville downstream to the confluence with the Roanoke River on John. H. Kerr Reservoir, including its tributaries Hyco River up to Rt. 738 bridge and Banister River up to the Banister Dam has

been updated. This advisory also recommends that no more than two eight-ounce meals per month of walleye or longnose gar species should be consumed. Mercury advisory exists for various species in the segment as well.

Fish Consumption Advisories issued in October 7, 2009 due to PCBs are listed below:

- *Lake Whitehurst watershed including Little Creek Reservoir arm*

The advisory for Lake Whitehurst (entire lake) has been expanded to include the Little Creek Reservoir arm of the lake. This updated advisory recommends that no more than two eight-ounce meals per month of carp or gizzard shad species should be consumed. A concurrent mercury advisory exists for this watershed. Yellow perch is no longer affected by the advisory.

- *Tabb Creek watershed*

Tabb Creek (entire creek, ~2 miles) near Langley Air Force Base, a tributary of Northwest Branch Back River is covered by an advisory. This advisory was updated and recommends that gizzard shad should not be eaten and that no more than two eight-ounce meals per month of croaker, striped bass, blue crab or oyster species should be consumed.

- *Poquoson River watershed*

The tidal portion of Poquoson River and its tributary Chisman Creek is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of gizzard shad species should be consumed.

- *Piankatank River and lower Dragon Run Swamp watershed*

The segment of lower Dragon Run Swamp and upper Piankatank River from Rt. 17 downstream to Deep Point Boat Landing (State Route 606) across from Piankatank Shores is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of gizzard shad species should be consumed. A concurrent mercury advisory exists for largemouth bass for the segment as well.

- *Pamunkey River watershed*

The segment of the Pamunkey River from Nelson Bridge Road (Route 615 bridge) downstream to the confluence with the Mattaponi River near West Point is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of gizzard shad species should be consumed. The previous advisory due to mercury contamination was expanded to cover an additional stretch of the river from Jacks Creek to West Point. The expanded segment is covered by both mercury and PCB advisories. .

- *Mattaponi River watershed*

The segment of the Mattaponi River from the Rt. 628 near gaging station downstream to the confluence with the Pamunkey River near West Point is covered by an advisory. This is an update of the 2004 advisory segment. The previous advisory segment due to mercury contamination was also expanded to cover an additional stretch of the river from Melrose Landing to West Point. The expanded segment is covered by both mercury and PCB advisories.

- *Mill Creek watershed*

Mill Creek (entire creek) near Fort Monroe is covered by an advisory. This advisory recommends that no more than two eight-ounce meals per month of gizzard shad species should be consumed.

- *Potomac River watershed*

The segment of the Potomac River Basin comprising the tidal portion of the following tributaries and embayments from the I-395 bridge (above the Woodrow Wilson Bridge) to the Potomac River Bridge at Rt. 301: Four Mile Run, Hunting Creek, Little Hunting Creek, Pohick Creek, Accotink Creek, Occoquan River, Neabsco Creek, Powell Creek, Quantico Creek, Chopawamsic Creek, Aquia Creek, and Potomac Creek is covered by an advisory. This is an update of the previous advisory and recommends that American eel species should not be eaten.

- **Special Blue Crab hepatopancreas consumption advisories due to polychlorinated biphenyls (PCBs) and/or Dioxin contamination**

Fish Consumption Advisories issued in January 23, 2009 due to PCBs/Dioxin are listed below:

- *King Creek watershed: PCBs*

The segment of King Creek (a tidal tributary of York River ~3.5 miles) is covered under a special advisory only related to the consumption of the hepatopancreas of blue crab. The advisory states DO NOT EAT crab's hepatopancreas ("mustard," green gland, or tomalley). This advisory applies only to avoiding eating the crab's hepatopancreas or "mustard". Crab meat is not subject to this advisory.

- *Southern Branch Elizabeth River watershed: PCBs and Dioxin*

The segment comprising the Southern Branch of the Elizabeth River and its tidal tributaries (~ 23 miles) is covered under a special advisory only related to the consumption of the hepatopancreas of blue crab. The advisory states DO NOT EAT crab's hepatopancreas ("mustard," green gland, or tomalley). This advisory applies only to avoiding eating the crab's hepatopancreas or "mustard". Crab meat is not subject to this advisory.

Shellfish Condemnations

As of December 2014, VDH has prohibited and/or condemned harvest of approximately 56 square miles of productive shellfish areas in the waters of Virginia. Another 5 square miles have been seasonally condemned, which restricts direct harvesting from 1 April to 31 October of each year. These areas are all located in the Chesapeake Bay and tidewater areas of the state, and include waters surrounding certain point source discharges, as well as areas with elevated fecal coliform bacteria concentrations or other health-related pollutants. Shellfish may be harvested from most restricted areas; however, they must first be relayed to harvest “approved” waters for depuration for 15 days before marketing. Relaying is only allowed when the water temperature is above 50°F. Shellfish closures and advisories can be found on the VDH Division of Shellfish Sanitation website: http://www.vdh.virginia.gov/EnvironmentalHealth/Shellfish/.

Fish Tissue Contamination

- *Routine and Special Study Fish Tissue Data*

This section summarizes the fish tissue contaminant data collected, analyzed and/or evaluated during the period covered in this report. The data were collected via DEQ's routine monitoring of fish and sediment samples for contaminant analysis in the state river basins as well as from follow-up and special monitoring studies conducted once the routine program identified potential problem areas. The data reviewed for this report covers data collected from 2009 through 2014. Fish tissue contaminants data for routine monitoring are posted on the DEQ website at http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/Fish

TissueMonitoring.aspx. All of these data have been reviewed by the VDH.

- *Virginia Water Quality Standard based Fish Tissue Value or Screening Value Exceedences*

The monitoring station data list found on the DEQ website at http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/FishTissueMonitoring.aspx includes the approximately 500 stations that DEQ sampled in its routine rotational river basin monitoring program (including follow-up monitoring) between 1995 and 2014. It also tabulates the number of exceedences of human health screening values for those routine monitoring stations where there were exceedences for one or more contaminants in edible fish fillets or shellfish. Contaminant screening values are computed using EPA risk assessment techniques for non-carcinogenic and carcinogenic effects and are based on the same fish tissue concentrations that are the basis for the numerical water quality criteria that are designed to prevent fish contamination. These stations were not randomly selected. Instead, many of the stations were targeted for sampling because of potential or known water pollution problems identified via a search of historical data and reports.

- Selection Basis for Stations Discussed

This report summary highlights those stations where current contaminant levels alone or in combination with other data and studies were:

a) at a Virginia Department of Health ("VDH") level of concern for human health requiring a fish consumption advisory or advisory extension or

b) at a VDH or DEQ level of concern requiring special follow-up studies (most are listed at http://www.deq.virginia.gov/Programs/Water/ReportsPublications.aspx, or

c) below levels of concern where VDH determined the existing fish consumption advisory could be lifted due to a decline in levels of contamination. A complete list of fish advisories in Virginia can be found at VDH fish consumption advisories webpage.

During this period DEQ and the VDH were also able to complete risk evaluations at several sites reported for ongoing or future evaluation in previous editions of this report. These decisions are included in this report in order to finalize the information on previously reported potential human health concerns. This report does not highlight station exceedences where VDH determined, at the time of data review, that no further action was needed unless these stations were monitored as a follow-up to a VDH request for additional sampling.

Lead

- No Current EPA Screening Value for Lead in fish tissue

The specific toxicological information needed to calculate a screening value is not available for lead at this time and EPA does not have a screening value for lead in fish tissue. Therefore, DEQ cannot use a screening value to assess the data for lead found in fish tissue. To address this issue, DEQ reports any concentration of lead detected by our contract analytical lab to the VDH for its review and recommendations. To address this unusual situation in this report, all instances of lead detected at any concentration in fish tissue are noted in the monitoring station data list found on the DEQ website.

- 1993 - 1994 Lead Data Suspect Due to Laboratory Problems

Previous 305(b) reports noted that lead had been detected in at least some of the fish samples at each station sampled in 1994 as well as in 1993, and additional follow-up work was planned. Upon further investigation, DEQ identified detection limit problems at the contract laboratory. This made all of the lead concentrations for the 1993 - 1994 fish tissue samples suspect. Therefore, these lead concentrations were not used in the assessment of the 1993-1994 data and were not included in the Final 2016

monitoring station list associated with previous reports as exceedences. Furthermore, VDH did not consider the concentrations for the suspect lead data to be at levels of concern. In 1995 DEQ switched to another contract lab capable of detecting metals and organics at lower detection limits. Lead was detected in less than 4 percent of fish analyzed between 1995 and 1998. When DEQ re-sampled one of the 1994 stations with suspect lead levels (Mattaponi River) in 1996, lead was reported below detection limits (<0.1 ppm).

- VDH Requests for Follow-up Sampling

In subsequent monitoring years (1995 – 1998), lead was detected at 15 river basin stations. Of these 15 stations, VDH asked DEQ to follow-up with additional sampling at two sites sampled in 1997 (Kiptopeke State Park and Bagwell Creek). These two stations were re-sampled in 2000 and lead was not detected in any fish samples from Bagwell Creek. Lead was detected at the detection level of 0.1 ppm in only one of six fish samples (gray trout) at Kiptopeke State Park. These data were reported to the VDH and they did not recommend any further action.

Arsenic

There are some uncertainties associated with assessing potential health risks posed by arsenic in fish tissue. Arsenic does not have a high potential for bioaccumulation and is not a common contaminant in most fish samples. It is more likely to be detected in marine and estuarine species and is seldom detected in freshwater species. On the other hand, arsenic has recently been classified as a human carcinogen, making this an important potential contaminant in fish tissue. However, the carcinogenic potential of arsenic is associated with the inorganic forms of arsenic while organic forms of arsenic are not thought to be carcinogenic. DEQ has developed a fish tissue screening value for arsenic in fish tissue of 72 µg/kg based on its carcinogenic potential and DEQ intends this screening value to be applied to the inorganic form of arsenic. Unfortunately, all data available to DEQ for arsenic in fish tissue are total arsenic concentrations, which include both organic and inorganic forms. This makes assessing the potential for increased cancer risk due to total arsenic in fish tissue problematic. For the 305(b) assessment purposes, DEQ uses a conservative approach and assesses the fish tissue screening value for inorganic arsenic using the available total arsenic concentrations. This approach essentially assumes all total arsenic in fish tissue may be in the inorganic form. DEQ uses this approach in order to be protective and avoid underestimating potential human health risks but also recognizes that this is a conservative method. Some studies (primarily involving marine and estuarine species) show that estimates for the portion of inorganic arsenic in fish tissue is variable but may be only approximately 10% of the total arsenic concentration.

In the 305(b) assessment process, all fish samples that exceed 72 µg/kg total arsenic will be assessed as fully supporting with observed effects, but will not result in an impaired assessment. The purpose of this conservative assessment is to identify areas with elevated levels of arsenic in fish tissue to help DEQ determine where additional investigation may be warranted. Additionally, all fish samples that exceed 72 µg/kg total arsenic are identified and reported to the VDH for their evaluation. EPA has recently developed a method for analyzing the speciation of arsenic in fish tissue which can differentiate inorganic forms of arsenic. However, this new method is complicated and is far more costly than total arsenic analysis. This new method may be useful in the future in identifying the inorganic arsenic concentrations in fish at sites where additional, more detailed investigations may be considered necessary. It is likely that during the current assessment period the fish tissue screening value could be modified based on an updated fish tissue consumption rate.

Polychlorinated Biphenyls (PCBs)

- Shenandoah River and South and North Forks of the Shenandoah River Fish Consumption Advisory

VDH reviewed the fish PCB data collected in 1996 and 1999 from stations on the Shenandoah River and South and North Forks of the Shenandoah River that contained PCBs above the VDH level of concern. Because these fish were from areas currently subject to a fish consumption advisory

established in 1989, VDH determined that no further action was needed. The advisory has since been modified.

- Roanoke (Staunton) River Fish Consumption Advisory

Data collected by DEQ in 1993 during a special Roanoke (Staunton) River basin study led VDH to issue a fish consumption advisory in 1998. The area covered by the advisory was expanded in 1999 in response to additional DEQ sampling results above the VDH level of concern of 600 parts per billion. (See the DEQ website for additional information). DEQ is now focusing on identification of potential point sources for the contamination.

- Dan River Fish Consumption Advisory

Data collected by DEQ in 1999 from the Dan River showed elevated levels of PCBs in some species of fish from various areas of the river. On December 27, 1999 the VDH issued a fish consumption advisory for the Dan River from the Virginia-North Carolina border (north of the VA Rt. 62) downstream to the Kerr Reservoir at the Staunton River State Park. The fish consumption advisory recommends that no more than two eight-ounce meals per month of flathead catfish or channel catfish be consumed. The advisory has since been modified.

- Levisa Fork Fish Consumption Advisory

In 1997, DEQ included a station on the Levisa Fork at the state line in its routine river basin rotational sampling because PCBs had previously been detected in fish at this location. Three out of four of the fish species samples collected at Levisa Fork in 1997 exceeded the 600 parts per billion level of concern for PCBs established by VDH for issuing fish consumption advisories. The VDH issued a fish-eating advisory for a 12-mile stretch of Levisa Fork in 1999. In response to a request from VDH, DEQ conducted a special fish and sediment study in Levisa Fork in 2000 in an attempt to bracket the extent of fish contamination. The VDH reviewed these new data and determined that the only fish that exceeded their level of concern were from areas currently subject to a fish consumption advisory. Therefore, VDH determined that no further action was needed at that time. Results of the 2002 DEQ fish tissue monitoring prompted the VDH to modify the existing fish consumption advisory to apply to all fish in this section of the river.

- Deep Creek Follow-up Sampling

VDH asked DEQ to resample Deep Creek (Southern Branch of the Elizabeth River) in 2000 because a gizzard shad sample collected at that station in 1998 exceeded the screening value for PCBs. DEQ had also conducted a special study in the Elizabeth River in 1993. PCB levels in all species collected at the Deep Creek station in 2000 except gizzard shad were below the VDH 600 ppb level of concern. Additional DEQ sampling in the Elizabeth River system was conducted in 2001. Analytical data from these 2001 fish samples were received by DEQ from the laboratory in the summer of 2002. Following the review and evaluation of these 2001 fish contaminant data, VDH included Deep Creek as part of the Lower James River PCBs advisory zone.

- Four Mile Run Special Study

Samples were collected in Four Mile Run during October 1997 in response to concerns about run-off problems from the nearby Potomac Yard in Northern Virginia. The local Health Department made the request for the special study via the DEQ Northern Regional Office in response to citizen concerns. VDH reviewed the data results and determined that the level of contaminants (PCBs, total chlordane and total PAHs) posed no significant risks to human health. In 2004, VDH issued a fish consumption advisory due to PCBs for this watershed.

- James River 1997 Fish Study of PCB Levels

The US Fish and Wildlife Service had expressed concern due to the presence of PCBs in fish tissue from the James River (River Miles 76.0-69.0) and the DEQ's "low" priority designation during its review of DEQ's final 303(d) TMDL (Total Maximum Daily Load) Priority List for 1996. The Service also expressed concern that the area was a roosting habitat for the bald eagle and limited fish tissue data were available for the river segment. In addition, DEQ-Piedmont Regional Office ("PRO") staff identified high concentrations of polychlorinated terphenyls (PCTs) in sediment in Bailey Creek. So in 1997, 45 fish tissue samples were collected from seven stations in the James River and its tributaries in the vicinity of Hopewell. The study was a joint effort between DEQ-PRO and Central Office staff, and involved fish tissue and sediment collections. These samples were analyzed for PCBs, PCTs, and chlorinated pesticides. Thirty-five of the 45 fish tissue samples had PCB levels in excess of the DEQ screening value; however, only one sample had a PCB concentration above the VDH advisory level. Fish tissue data were transmitted to PRO staff during November 1998. During early December 1998 PRO staff made a data report presentation to other DEQ staff and VDH personnel. An old landfill in Hopewell was identified as the source of PCBs and PCTs to the James River system. At PRO's request, USEPA Superfund monitoring staff sampled the landfill area and creek running through it in January 1999 and determined that the site contamination was not sufficient to warrant Superfund cleanup. EPA found PCTs upstream of the landfill and suggested that old industrial sources might be contributing to the contamination. At the request of the industry, PRO sampled stormwater outfalls at the headwaters of the creek for PCTs and PCBs in May 1999. PRO found PCTs in the 1 to 5 ppm ranges and PCBs in the 0.2 to 1.6 ppm range in sediments. These results were below the clean-up requirements of EPA Superfund, and the case was considered resolved pending further information. VDH asked DEQ to resample Bailey Bay in 2001 or 2002. DEQ re-sampled Bailey Bay in 2001. Analytical data from these 2001 fish samples were received by DEQ from the lab in the summer of 2002. DEQ and the VDH reviewed the 2001 fish-contaminant data to determine the need for appropriate follow-up action. After reviewing the data, the VDH issued a fish consumption advisory in July 2002. This fish consumption advisory is described above in the section on fish consumption advisories and restrictions. DEQ re-sampled additional fish from this section of the James in 2003 and 2005 to investigate this matter further.

- Revisit Potomac River Fish Consumption Advisory Area

At the request of VDH, DEQ re-sampled the Potomac River and Virginia tributaries in 2000. Some carp and channel catfish samples from the Potomac embayment stations had PCBs higher than the VDH level of concern of 600 ppb for PCBs. However, all these stations are within sections of the river where a fish consumption advisory is already in effect. Therefore, based on the year 2000 monitoring data, the VDH has determined that no further action is warranted at this time. The advisory has since been modified.

- Mountain Run and Bull Run

During this period, the DEQ completed follow-up monitoring of fish and sediment from Mountain Run and Bull Run. Latest sampling results in 1999 found PCBs and PAHs in the fish but not at the VDH levels of concern. In 2004, VDH issued fish consumption advisory due to PCBs for both bodies of water.

- New River Fish Consumption Advisory Area

Based on data from fish collected by DEQ in 2000, VDH issued a fish advisory for the New River from the Rt. 114 bridge north of Radford to the Virginia-West Virginia state line. This new fish consumption advisory applies only to carp and recommends that no carp be consumed from the affected portion of the river. Based on DEQ data collected in 2000 and discussions with VDH, DEQ collected additional samples from the New River in October 2001 at the following locations; downstream of Claytor Lake dam, downstream of Radford, near Whitethorne, near Pembroke and at Glen Lyn. Additional sampling to gain data in this section of the New River was performed for 2002. The VDH reviewed these data and determined that no adjustments were required to the fish consumption advisory issued in August 2001. The advisory has since been modified.

- Bluestone River Fish Consumption Advisory Area

Based on data from fish collected by DEQ in 2000, VDH issued a fish advisory on August 6, 2001 for the Bluestone River from the Rt. 460-bridge crossing south of Bluefield to the Virginia-West Virginia state line. This new fish consumption advisory applies only to carp and recommends that no carp be consumed from the affected portion of the river. Based on DEQ data collected in 2000 and discussions with VDH, DEQ re-sampled this area on the Bluestone River near the sewer plant road near Route 717 and near the town of Yards in 2002. The VDH reviewed these data and determined no adjustments were required to the fish consumption advisory issued in August 2001. The advisory has since been modified.

Mercury

- North Fork Holston Mercury Monitoring

A station on the North Fork of the Holston River exceeded the screening value for mercury in 1997. This area was already under a long-term fish consumption advisory prohibiting the taking of fish from these waters for human consumption due to historical mercury contamination from a Superfund site. DEQ fish tissue monitoring data from 1997 and 2002 showed no fish samples contained mercury at concentrations greater than the FDA action level for mercury (1.0 ppm). However, some samples of rock bass were above the Virginia Department of Health's level of concern for mercury of 0.5 ppm. Subsequent monitoring data in 2003 and 2005 indicated elevated mercury above the FDA action level in several species.

- Shenandoah River Mercury Monitoring

DEQ's Valley Regional Office has an ongoing monitoring program for mercury in fish tissue, water and sediment in the South River and South Fork Shenandoah River. There have been restrictions or health advisories on consumption of fish from portions of the South and South Fork Shenandoah Rivers since the 1970s. A fish consumption advisory in some form has been in place for some portions of this river system since the 1980s. The mercury contamination originated from historic practices at the E.I. DuPont Plant in Waynesboro. In a settlement between DuPont and the Commonwealth in the early 1980s, a trust fund was established to support monitoring in the river for a projected 100-year period. Fish were most recently sampled in 1999, 2001, 2003, 2005, 2007, and 2012. The results are available on the DEQ website at http://www.deq.virginia.gov/Programs/Water/WaterQualityInformationTMDLs/WaterQualityMonitoring/FishTissueMonitoring/ShenandoahMercury.aspx. The VDH has evaluated all these data as well as recent recommendations from the National Academy of Sciences regarding mercury toxicity and assumptions of fish consumption rates. Based on their review, the VDH has changed their guidelines for issuing fish consumption advisories for mercury and has lowered their level of concern from 1.0 ppm to 0.50 ppm mercury. This is based on a new assumption of two eight-ounce meals per month, while the old screening value was based on approximately one meal per month. Based on the new, lower level of concern for mercury the VDH determined that the existing fish consumption advisory should remain in effect and be expanded into some additional portions of the river system. The revised advisory also contains updated recommendations on the amounts of fish that can safely be consumed in different sections of the rivers. The VDH stated that this action was not due to changes in mercury levels in the fish but was due to the VDH "lowering the amount of mercury recommended for fish consumption to provide more protection to the public". More information regarding mercury fish consumption can be found at http://www.vdh.virginia.gov/epidemiology/DEE/PublicHealthToxicology/PressReleases.htm. DEQ continues to monitor mercury contamination in this river system through regular meetings with stakeholders, review of literature, and communications with other experts in the field. Additional fish tissue monitoring for mercury contamination in this river system is on-going as part of the 100-year monitoring plan.

- Dragon Swamp Mercury Monitoring

Based on mercury levels detected in fish collected during the routine rotational river basin

sampling in 1998, VDH requested that DEQ resample the site in 2000. One of seven species tested at this site in 2000 exceeded the VDH screening value of 0.50 ppm. This 2000 datum was for a largemouth bass at 0.59 ppm; in 1998 the largemouth bass sample was analyzed at 1.9 ppm. DEQ sampled the site again in 2002. As a result of the 2002 DEQ sampling the VDH issued a fish consumption advisory for largemouth bass for a section of the Dragon Swamp in 2003. This is discussed above in the section on fish consumption advisories and below under "mercury in swamp waters".

- Tennessee/Big Sandy River Basin Mercury Monitoring

The VDH had concerns about mercury concentrations in whole fish from two stations (Cranesnest River and J. W. Flannagan Reservoir) sampled during the DEQ 1991 coalfields study. However, VDH could not draw any significant conclusions on associated health risks from the whole fish data. DEQ re-sampled these two stations in 1997 for mercury analysis of edible fillets. VDH has reviewed the data from 1997 and determined that the reported levels were not at a level of concern and that no additional sampling from these sites was necessary.

Mercury in Swamp Waters

In recent years there has been increasing interest in mercury contamination in fish tissue. A number of studies around the country, from the Everglades through the swamps of the southeastern United States as well as in lakes, bogs and wetlands in New England, Wisconsin and Minnesota have shown that top level predator fish species analyzed in these habitats frequently contain elevated levels of mercury. A number of these studies show that there are no known local sources of mercury in these areas and suggest that deposition of airborne mercury is a suspected source. These water bodies share natural, physical characteristics of low pH, high organic content and still or slow moving current which promote the natural methylation of mercury into the highly bioaccumulative compound methylmercury. Increased natural production of methylmercury increases the possibility that the mercury content of fish will be elevated, especially in upper level predators. This emerging realization that some water bodies may be naturally more prone to elevated levels of bioaccumulative mercury, along with the new, lower fish mercury concentration that is now being used by the VDH as an acceptable level of mercury in fish tissue has prompted DEQ to investigate potential mercury contamination more closely.

DEQ has traditionally focused the fish tissue monitoring program to monitor sites with suspected sources of pollution and apparently unpolluted habitats such as swamps were given low priority for monitoring. In order to investigate the new concern for this swamp water and mercury methylation issue, DEQ has begun to sample these habitats in more areas where there are no known or suspected sources of mercury but where the environmental conditions are favorable for mercury methylation. As a result of this sampling in 2002, elevated levels of mercury were discovered in top-level predator fish species in three swamps or “blackwater” rivers.

In October 2003, VDH established fish consumption advisories due to elevated mercury levels detected in fish-tissue in top-level predator fish species for three swamps or “blackwater” rivers. These fish consumption advisories are for the Dragon Swamp /Piankatank River, the Great Dismal Swamp Canal and the Blackwater River. These fish consumption advisories are described in more detail in the section on fish consumption advisories.

Similar elevated levels of mercury in fish-eating species of fish have been noted in similar habitats in the southeastern United States as well as lakes, bogs and wetlands in New England, Wisconsin and Minnesota. In many of these areas there are no known sources of mercury. Deposition of airborne mercury has been identified as a possible source of the mercury to the swamp water, where methylation takes place resulting in bioaccumulation up the food chain, resulting in elevated levels of mercury in the fish eating fish. This is also considered a possibility in these swamp waters in Virginia. DEQ is investigating this possibility as well as other potential sources of mercury to these water bodies. DEQ has initiated additional monitoring of fish in these areas to better understand the extent of the elevated mercury concentrations.

DDT/DDE

- Two Lakes at Tidewater Community College

The DEQ Waste Division requested VDH review of DDT/DDE concentrations in whole fish collected from two Tidewater Community College lakes at a Superfund site. The VDH preferred edible fillets but found that even the concentrations in the whole fish were below levels of concern. At the request of citizens, DEQ collected fish from the two lakes for analysis of edible fish fillets in 2000 and the VDH has reviewed these data and determined that the low concentrations in the fish present no health risks.

Dioxin

- Blackwater and Nottoway Rivers

Due to dioxin contamination by the Union Camp Company in Franklin, Virginia, a fish eating advisory was issued by the VDH in 1990 for portions of the Blackwater and Nottoway Rivers. Union Camp subsequently changed its process operations. At the request of the VDH, DEQ sampled one station each in the Blackwater and Nottoway Rivers in late 1997 for dioxin levels in fish. The results verified similar findings by Union Camp Company that the dioxin levels in the fish were below the VDH level of concern, and the advisory was lifted by VDH on March 26, 1998.

Kepone

- James and Chickahominy Rivers

From 1975 until 2000, DEQ, in consultation with the VDH, annually collected fish for kepone analysis from the James River downstream of Hopewell, in the vicinity of the mouth of the Chickahominy River and in the Hampton Roads area. Nine of the 253 fish samples collected and analyzed in 1994 exceeded the FDA action level of 0.3 ppm. In 1995 one sample out of 260 exceeded the 0.3 ppm action level. Since 1995, none of the edible fillet samples from the annual collections has exceeded the FDA action level. A biennium sampling schedule was followed from 2000 until 2004, which was then changed to a 5-year schedule. The last sampling was conducted in 2009.

Relationship between *Pfiesteria* and water quality

The 2002 water quality assessment included the sampling and analysis for a microorganism ***Pfiesteria piscicida.*** This microorganism has been linked to extensive fish kills in North Carolina estuaries. Leading experts from North Carolina State University and the Florida Department of Environmental Protection as well as other scientists have not identified the toxic microbe in samples from Virginia. However, *Pfiesteria piscicida* was found in several rivers in Maryland where fish kills occurred during the summer of 1997. No confirmed cases were found in the waters of Virginia during the 1999 summer season and at this time, DEQ has reserved judgment on water quality issues associated with *Pfiesteria*.

Once a fish kill involving lesions is reported and if *Pfiesteria piscicida* is considered a possible cause, DEQ will collect water samples for oxygen and other chemical parameters along with actual fish samples. Water samples are sent to Old Dominion University (ODU) for analysis and fish samples are sent to Virginia Institute of Marine Science (VIMS).

Reporting fish kills or fishes with lesions

DEQ has responsibility for investigating fish kills in Virginia waters. Call 1 (800) 592-54VA to be directed to the appropriate regional office.

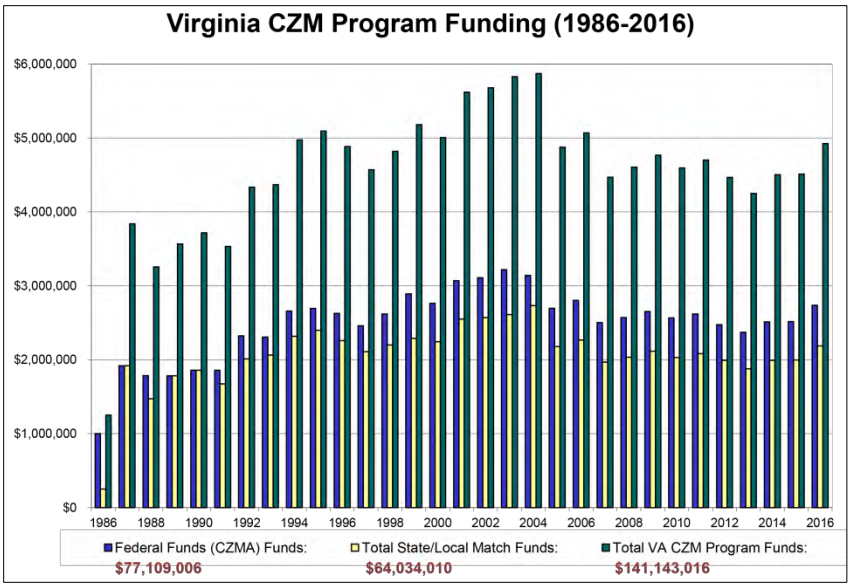
For any health related concerns, call the VDH hotline at 1 (888) 238-6154.

CHAPTER 7.6 VIRGINIA COASTAL ZONE MANAGEMENT PROGRAM

A. Description of the Virginia Coastal Zone Management Program

Virginia's coastal zone encompasses all of Virginia's Atlantic coast watershed as well as parts of the Chesapeake Bay and Albemarle/Pamlico Estuary watersheds. This coastal zone area, also known as Tidewater, Virginia, includes 29 counties, 15 cities and 42 towns as well as all waters within and out to the three-mile Territorial Sea boundary.

The Virginia Coastal Zone Management (CZM) Program was established in 1986 to protect and enhance Virginia's coastal resources. Virginia CZM is a network of state agencies and Tidewater local governments and the CZM laws and policies they implement. Through this network, the program manages sand dunes, wetlands, underwater lands, fisheries, point and nonpoint source air and water pollution, shoreline sanitation and a variety of other areas of particular concern such as coastal wildlife habitats and public access, waterfront redevelopment and underwater historic sites. See www.deq.virginia.gov/Programs/CoastalZoneManagement/Laws,Regulations,Guidance.aspx for more details about the laws and policies that define the program.



Executive Order No. 35 signed by Governor Terry McAuliffe in June 2014, continuing the Virginia CZM Program, directs all state agencies "to carry out their legally established duties consistent with this Program in a manner that promotes coordination among all government agencies." It is through this coordination that the Virginia CZM Program has been able to achieve great strides in achieving its goals and objectives." See www.deq.virginia.gov/Programs/CoastalZoneManagement/Laws,Regulations,Guidance.aspx for a list of the goals and go to www.deq.virginia.gov/Programs/CoastalZoneManagement/DescriptionBoundary/Goals.aspx to see what the program has accomplished toward reaching these goals.

Core regulatory agencies in the Virginia CZM Program network include the Marine Resources Commission (VMRC), the Department of Environmental Quality (DEQ), the Department of Game and Inland Fisheries (DGIF), the Department of Conservation and Recreation (DCR), and the Virginia Department of Health (VDH). Other agencies assisting with the Program include the Department of Historic Resources (DHR), Department of Forestry (DOF), Virginia Department of Agriculture and Consumer Services (VDACS), the Department of Mines, Minerals and Energy, the Virginia Institute of Marine Science (VIMS), the Virginia Economic Development Partnership (VEDP) and the Virginia Department of Transportation (VDOT). DEQ serves as the lead agency for Virginia's networked CZM Program and helps agencies and localities to develop and implement coordinated coastal policies.

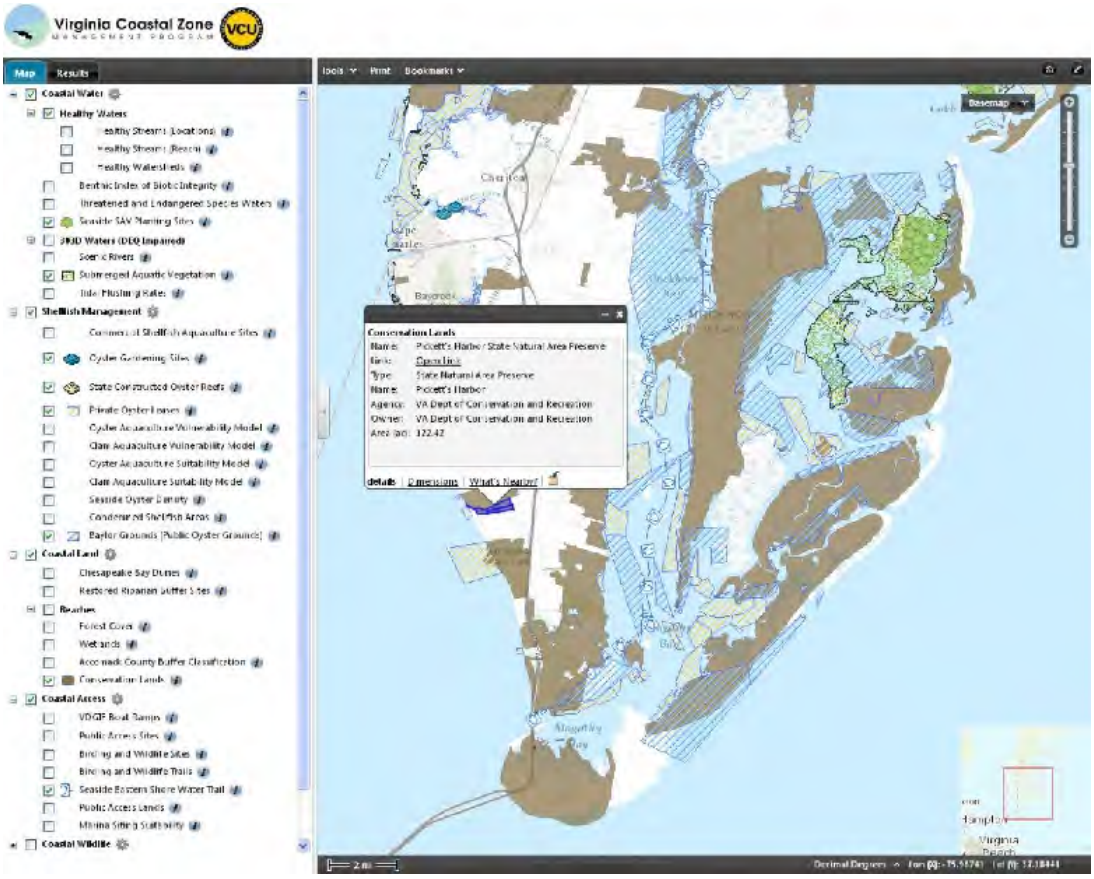
By virtue of having a federally approved coastal zone management Program, Virginia also has the authority to require that federal actions within the coastal zone be consistent with Virginia's CZM Program. Environmental impact review staff at DEQ review federal actions in the coastal zone for consistency with Virginia's CZM Program laws and policies.

B. Coastal Zone Management Act Funding Received by Virginia

In addition to providing a forum for development and coordination of cross-cutting coastal issues, the Virginia CZM Program provides grant assistance to state agencies and local governments. Having a federally approved coastal zone management program qualifies Virginia to receive just under $3 million per year in federal funds under a formula allocation based on miles of shoreline and coastal zone population. The Office of Ocean and Coastal Resource Management at the National Oceanic and Atmospheric Administration (NOAA) allocates these funds under the Coastal Zone Management Act (CZMA). These grant funds are 50% matched by Virginia's state agencies and local governments.

Since 1986, Virginia has received just over $77 million dollars in federal CZMA funds, matched by over $64 million in state and local funds, including match from the Virginia Water Quality Improvement Fund which finances nutrient reduction strategies being developed for the Chesapeake Bay and its tributaries – specifically design and installation of nutrient reduction technology at Chesapeake Bay watershed publicly owned wastewater treatment plants. These funds are used to implement the Virginia CZM Program and to carry out a broad scope of state and local projects in the areas of coastal technical assistance, enforcement, environmental management, habitat monitoring and restoration, land acquisition, local government planning and comprehensive plans, public access planning and construction, public education, shoreline management, special area management planning, wetlands surveys and policy, and water quality monitoring/protection and improvements. For more information about the federal CZMA funding Virginia receives, how this funding is dispersed and the results of this funding visit www.deq.virginia.gov/Programs/CoastalZoneManagement/Funds,Initiatives,Projects.aspx.

Virginia Coastal Zone Management Program Initiatives Benefiting Water Quality



Several initiatives exemplify the Virginia CZM Program's unique opportunity to fund and support projects that protect the Commonwealth's coastal resources, while encouraging intergovernmental coordination and partnerships with a broad constituency. Highlighted below are Virginia CZM Program initiatives that address water quality and focus on education, monitoring and restoration of living resources to improve water quality in Virginia's coastal waters.

1. *Virginia CZM Program GIS-Mapping Efforts: Coastal GEMS and Coastal VEVA*

A. Virginia Coastal GEMS

In February 2007, the Virginia CZM Program launched "Coastal GEMS" (Coastal Geospatial and Educational Mapping System) found at www.deq.virginia.gov/Programs/CoastalZoneManagement/CoastalGEMSGeospatialData.aspx. Coastal GEMS integrates and provides access to a wide range of coastal resource data, fact sheets, relevant

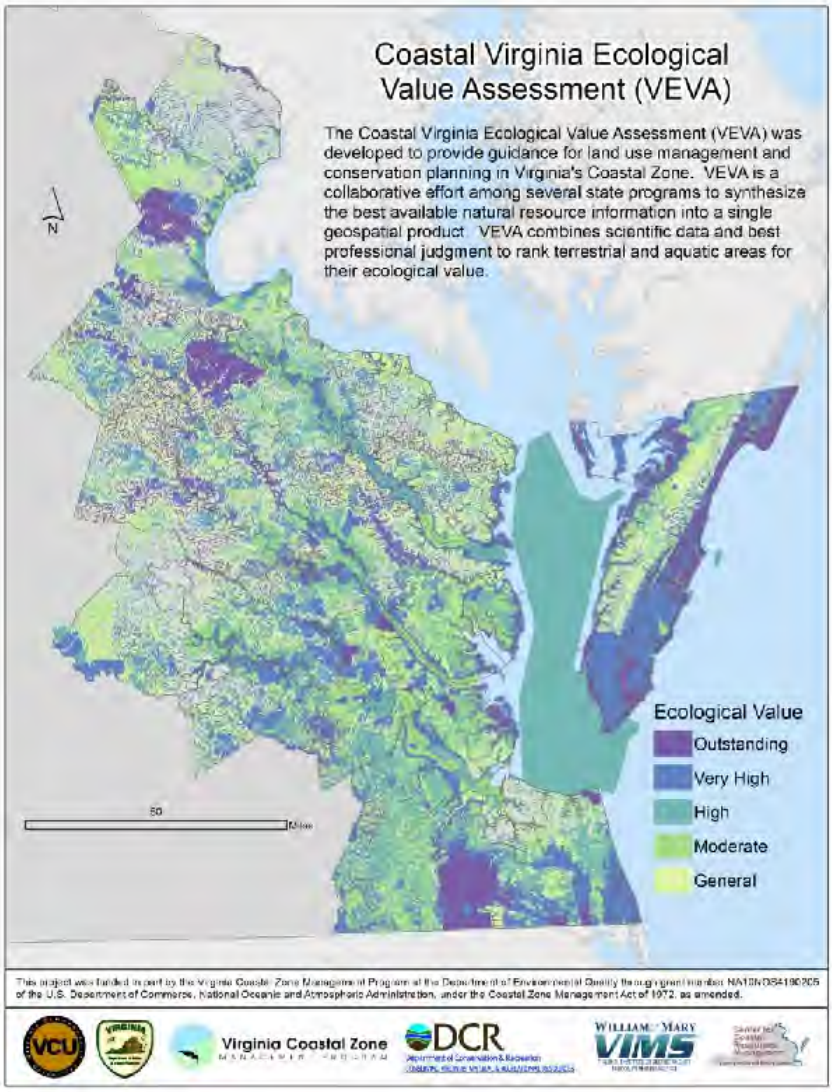
projects, regulatory information, and important Web links. Coastal GEMS is a robust, one-stop, data gateway for federal, state, and local government decision makers. It facilitates data sharing among governments, NGOs, and the general public and promotes standards for environmental data management within the region. Coastal GEMS allows its users to explore and describe patterns and relationships among water and land ecosystem elements across broad (i.e., landscape-level) spatial scales.

The development of Coastal GEMS was a large-scale, multi-partner effort to create a "vision" or map of the ecologically and economically significant aquatic (marine and freshwater) and terrestrial resources found within Virginia's Coastal Zone. Although spatially displayed data for aquatic and terrestrial ecosystems are becoming more and more accessible through the Internet, often these data are sequestered in different agencies' and organizations' websites and are not joined into one central application to allow all users equal and efficient access. The vision was to build this type of access. Seeing the resources in one big picture could simplify the task of connecting local land use planning decisions to state and federal water use policies. A stronger understanding of how activities on the land and in the water affect one another would enable everyone to better protect and manage coastal resources in a logical and sustainable fashion - something critically needed in light of today's increasing development pressures.

The data which are being incorporated into Coastal GEMS have been the result of collaborative discussions and data-sharing efforts between many state and local agencies with a vested interest in Virginia's coastal zone and the Virginia CZM Program will continue to explore opportunities to include additional data layers from partner agencies as they are developed. The Virginia CZM Program has also funded many data development projects which are represented in Coastal GEMS data layers.

The availability of adequate coastal resource data is essential to improving decision-making at the state and local level. By mapping the best remaining blue and green infrastructure in coastal Virginia, the Virginia CZM Program's Coastal GEMS website provides an easy-to-access, visual reference for localities where vital coastal resources are located. The Virginia CZM Program continues to work closely with the Center for Environmental Studies at Virginia Commonwealth University, Worldview Solutions, Inc. and all its data-sharing partners to enhance the interface, tools, data, and information within Coastal GEMS. Coastal GEMS is now a dynamic Internet mapping application with aerial imagery, reference data layers such as roads and streams, and over 80 data layers of land and water coastal resources, models and examples for conservation planning. Unique selection tools allow you to generate tables of coastal resource information for a selected area and mapping tools allow you to easily investigate and navigate through the coastal zone and create maps that can be exported or printed for further use and analysis.

The divisions of state and local management of Virginia's coastal resources are complex and difficult for the general public to understand. In addition to the mapping component of Coastal GEMS, the Virginia CZM Program created "fact sheets" for each data layer to break down the complexity of coastal resource management. The fact sheets provide brief information and links to in-depth information on:



- The value of the resource (ecological, economic, and social).
- Management of the resource (at local, state, and federal levels).
- Why and how the data was developed.
- How to directly download the data or who to contact to obtain the dataset.
- Future directions if the data is associated with a long-term funded project.
- Frequently asked questions received from the general public.

The Virginia CZM Program released an improved version 2 of Coastal GEMS in 2008 and in 2013 released version 3 with additional basemaps, improved cartography, user markup and search features, and improved browser compatibility. A version 4 of Coastal GEMS is currently in the works incorporating updates that will allow users to display VBMP imagery and additional basemaps, load map services from outside sources, and view 3D visualizations of elevation and sea level rise data within Virginia's coastal zone. Version 4 updates will also include the addition of map stories to Coastal GEMS with focuses on data such as Coastal VEVA, SAV, oysters, and land conservation, as well as a new Coastal GEMS landing page with information about the Coastal GEMS application, data and partners, and links to map stories. CZM staff created and implemented a Coastal GEMS training program for state agencies, local governments, and conservation organizations including: a presentation about Coastal GEMS and why/how it was created, a live demo of Coastal GEMS which is tailored to the specific needs of the audience, and a handout with info about Coastal GEMS and the data layers available. Info regarding GEMS training was posted to GEMS website and publicized to CZM partners. The CZM Program also plans to develop a secondary education curriculum and has presented on the use Coastal GEMS in an educational context at the Virginia Environmental Education Conference.

For more information on Coastal GEMS and to see a full list of geospatial data available, please visit www.deq.virginia.gov/Programs/CoastalZoneManagement/CoastalGEMSGeospatialData.aspx *or contact Nick Meade at (804) 698-4297 or Nick.Meade@deq.virginia.gov.*

B. Coastal VEVA

Many years ago, the Virginia CZM Program envisioned a comprehensive planning tool that would streamline use of all state natural resource information into a single data set facilitating regional and local land-use management and conservation planning in the coastal zone. A collaborative effort led and funded by Virginia CZM culminated in FY 2010 (Task 11). This effort included key natural resource agencies and resulted in the Coastal Virginia Ecological Value Assessment (VEVA). Coastal VEVA integrates elements of more than 40 different data sets funded by the Virginia CZM Program alone, totaling approximately $1.3M.

Research and data collection that ultimately became the foundation for VEVA began in 1988 with CZM funded conservation planning in Virginia's Lower Peninsula (FY 1988 Task 13.b). Following this effort and throughout the 1990's, CZM funded natural heritage inventories in Virginia Beach, the Albemarle-Pamlico Estuarine region and Northampton County as well as an interstate study of the Neotropical Migratory songbird corridor in New Jersey, Delaware, Maryland and Virginia.

The idea of creating a synthesis of the multitude of this and other contributing state natural resource data layers was brought up at a 2001 Coastal Partners Workshop. Participants agreed that the Virginia CZM Program should create a map of the best remaining coastal lands and waters, in other words the best remaining "green" and "blue" infrastructure. In response, the Virginia CZM Program crafted a Section 309 strategy beginning in FY 2003 that focused on data collection and data synthesis. Grants were awarded to DCR/Natural Heritage for priority conservation areas, to VCU for in-stream assessments, and to VIMS for blue infrastructure maps. In 2008 work began on synthesizing the blue and green infrastructure layers. The Virginia Department of Game and Inland Fisheries (DGIF), Virginia Department of Conservation and Recreation – Division of Natural Heritage (DCR-DNH), and Virginia Commonwealth University – Center for Environmental Studies (VCU-CES) collaborated to combine conservation information and priorities into a unified dataset of priority conservation areas. While the PCA assessed priorities on land, incorporating both stream and watershed health, it did not include all ecologically valuable regions within Virginia's tidal waters. Coastal VEVA builds on the PCA and incorporates an

assessment of estuarine natural resources recognizing that ecological value of Virginia's coastal lands and waters are inextricably linked—with land use decisions on the upland ultimately affecting water quality and habitat health in receiving waters. The estuarine component was produced by VIMS College of William and Mary Center for Coastal Resource Management through a series of grants. Coastal VEVA is defined as lands, aquatic resources and surface waters identified as important for conservation of Virginia's wildlife, plants, and aquatic and natural communities. The identified lands, aquatic resources and waters can be used to prioritize areas for preservation, protection or specific management action.

An update to Coastal VEVA is currently in the works through Virginia CZM Program funding to DCR-DNH, DGIF, and VCU CES. DCR-DNH is updating their Virginia Natural Landscape Assessment using the 2011 NLCD and DGIF is updating their Priority Wildlife Diversity Conservation Areas synthesis (including updates to their Tiered Species Habitat, Anadromous Fish Use Waters, and Unique Terrestrial and Aquatic Areas datasets). Once the updates from DCR and DGIF are complete, VCU CES will compile all of the data that make up the Coastal VEVA synthesis (including the DCR-DNH and DGIF datasets as well as additional data layers from VCU and VIMS that have been updated since VEVA was originally created) and run the VEVA model update.

To view an interactive version of the Coastal VEVA data layer as well as an informative fact sheet (complete with links to download the data layer and its various inputs from our partners), visit the Virginia CZM's web mapping application Coastal GEMS at www.deq.virginia.gov/Programs/CoastalZoneManagement/CoastalGEMSGeospatialData.aspx. *For more information contact Nick Meade at (804) 698-4297 or Nick.Meade@deq.virginia.gov*

2. *Virginia Coastal Nonpoint Source Pollution Program*

In 2001, Virginia became the sixth state to receive full approval of its *Coastal Nonpoint Pollution Control Program* from NOAA and EPA. Development of the program was initiated in the fall of 1992 in response to Section 6217 of the Coastal Zone Management Act Reauthorization Amendments of 1990. Section 6217 of the Act requires that states with an approved coastal zone management program, develop a Coastal Nonpoint Source Pollution Control Program. The statute is meant to restore and protect coastal water quality through the application of economically achievable "best management practices" implemented through enforceable state policies and mechanisms. The federal government defines state enforceable policies and mechanisms as state and local regulatory controls and/or non-regulatory incentive programs combined with state enforcement authority.

There are 56 management measures contained in the *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, a comprehensive technical document issued by EPA on methods to abate and control nonpoint pollution in coastal areas. The chapters include management measures in the following areas: agriculture, forestry, urban areas, marinas and recreational boating, and hydromodification (channelization and channel modification, dams and streambank and shoreline erosion). This document is available at www.epa.gov/owow/nps/MMGI/.

In order to gain approval of its Coastal Nonpoint Pollution Control Program, Virginia was required to show that:

1) State programs include appropriate management measures (defined in the above guidance) to control NPS pollution;
2) The state has a means of implementing the management measures, and;
3) The state has sufficient statutory authority and enforcement capabilities to ensure implementation of management measures to reduce NPS pollution impacts on coastal resources.

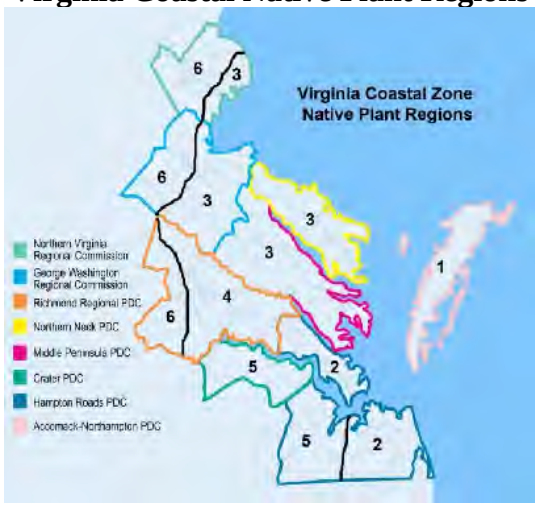
With approval of its Coastal Nonpoint Pollution Control Program, Virginia remains eligible for full funding under the Coastal Zone Management Act and Section 319 of the Clean Water Act.

Following are some of the projects that contributed to the approval of Virginia's Program:

- A series of workshops on the proper use of irrigation systems and development of informational material on irrigation best management practices;
- Development of a web-enabled database for use by local government to track erosion & sediment control activities; development of a model local stormwater ordinance; and an economic evaluation of incorporating BMPs into site design;
- Development of shore lands planning protocol for use by local governments to enhance planning capabilities for areas adjacent to shore lands;
- A statistical analysis of the impact of channelization activities and dams in Tidewater Virginia on in-stream & riparian habitat;
- A plasticulture guidebook for local government and farmers recommending practices to protect water quality for operations using plastic mulch;
- Development of the Virginia Clean Marina Program to provide technical assistance to marinas and recreational boaters.

See the most recent Virginia Nonpoint Source Management Plan annual report to EPA here. http://www.deq.virginia.gov/Portals/0/DEQ/Water/NonpointSource/NPSAnnualReports/2016%20Virginia%20NPS%20Annual%20Report.pdf

Virginia's Coastal Nonpoint Pollution Control Program is facilitated by the Virginia Coastal Zone Management (CZM) Program and implemented by CZM agency partners such as the Virginia Department of Environmental Quality (DEQ), the Virginia Department of Conservation and Recreation (DCR), the Virginia Department of Forestry (DOF), the Virginia Marine Resources Commission (MRC), Virginia Institute of Marine Science (VIMS) and Virginia Commonwealth University (VCU) along with local and regional governments from eight coastal planning districts.



With no current appropriation to fund the Coastal Nonpoint Pollution Control Program, Virginia is addressing non-point pollution issues in the coastal zone through the Department of Conservation and Recreation's Healthy Waters program, providing support and technical assistance to local and regional government water quality protection, green infrastructure and sustainable shoreline planning projects.

For more information, contact Beth Polak, Coastal Planner at the Virginia CZM Program, 804-698-4260 or Todd Janeski,804-371-8984 Healthy Waters Program Manager.

3. Increasing the Availability and Use of Virginia Native Plants

In spring 2009, the Virginia CZM Program and its partners launched the *Plant ES Native*s campaign on Virginia's Eastern Shore using proven social marketing tools and techniques with a focus on increasing the use of Virginia native plants for their habitat, water quality and many other values. The campaign has been a model for additional regional campaigns funded by the Virginia CZM Program on the Northern Neck – *Plant NNK Natives*, in Northern Virginia – *Plant NoVA Natives* and a campaign being developed in the George Washington Regional Commission area – *Plant Central Rapp Natives*. A strategic plan was completed to increase native plant use and vegetative cover in the Hampton Roads in early 2016. Components of the *Plant ES Natives Campaign* strategy - such as a regional plant guide (based on the *Flora of Virginia* published in December 2012 - http://floraofvirginia.org/), - have been easily transferrable to address barriers common in all the regions to planting

Virginia Coastal Native Plant Regions

The Virginia CZM Program hopes to have a campaign in every coastal planting region – map above. These native plant regions were delineated by DCR Natural Heritage. The map shows the alignment of these planting regions with Virginia's 8 coastal planning district commissions.

natives. Regional native plant guides are now available for Northern Virginia, Northern Neck, Eastern Shore, Southeast Virginia (including Hampton Roads) and one is under development for the Central Rappahannock. A regional guide for the Richmond area is planned in 2017. Many of the same organizations are participating on the regional campaign steering teams, including planning district commission and local government staff, state agency staff, local chapters of the Virginia Native Plant Society, Master Gardeners, Master Naturalists, Virginia Soil and Water Conservation Districts.

Although the Virginia CZM Program's federal CZMA funding must be spent in Virginia's coastal zone, the efforts the program and its partners have generated interest in western areas of the state (a regional native plant guide is also available for the northern Piedmont), and presented an opportunity for the program to encourage and support state-wide coordination and collaboration on native plant marketing. In 2011, the Virginia CZM Program reached out to other state and regional focused partners engaged in native plant marketing efforts and initiated the ***Virginia Native Plant Marketing Partnership*** (VNPMP). The goal of the VNPMP is to *identify opportunities to collaborate and partner on Virginia native plant communication and marketing efforts and form a cohesive and coordinated strategy to encourage the use of native plants coastal zone wide for their many benefits and help meet Virginia's habitat restoration and water quality goals, specifically TMDL goals.*

One of the goals prioritized by the VNPMP members was support for the development of a Chesapeake Bay Landscape Professional (CBLP) Program to create a network of certified professionals who will be better stormwater partners and environmental stewards. This program was piloted in the fall of 2016 in Virginia, Maryland and DC, and will be available across the watershed in 2017. For more information, visit http://cblpro.org/about-cblp/.

Virginia.Witmer@deq.virginia.gov

4. Virginia Coastal Needs Assessments and Strategies

Section 309 of the Coastal Zone Management Act (CZMA) establishes a match-free coastal zone enhancement grants program to encourage coastal states to develop new enforceable policies. The National Oceanic and Atmospheric Administration (NOAA) awards CZMA funds and requires that coastal states assess changes, progress and new issues in the nine areas below every five years.

1. Wetlands
2. coastal hazards
3. public access
4. marine debris
5. cumulative and secondary impacts
6. special area management planning (SAMPs)
7. ocean resources
8. energy and government facility siting
9. aquaculture

After completion of a draft assessment, the Virginia CZM Program's Coastal Policy Team (CPT) meets to review and prioritize (high, medium or low priority) the nine assessment areas for the next five years of work and to develop strategies to address the priority areas. During the reporting period, the 2011-2015 Coastal Enhancement Strategies were completed, the 2015 Assessment was completed, and projects

were begun to address the 2016-2020 Strategies. All of the projects undertaken to implement the strategies have either direct or indirect impacts to water quality.

A. Virginia's 2010 Coastal Needs Assessment and FY2011 - FY2015 Strategies

Based on needs identified in the 309 assessment process and Coastal Policy Team discussion, the Virginia CZM Program focused its efforts on the following assessment areas and issues between 2011 and 2015.

- Cumulative and Secondary Impacts of Growth and Development (CSI)
  - Working Waterfronts
  - Living Shoreline Policies
  - Local Shoreline Plans
  - Water Quality: Urban, Transitional and Rural Areas
- Special Area Management Plans (SAMPs)
  - Seaside SAMP
- Ocean Resources
  - Ocean Planning
  - Marine Mammal Mapping
  - Marine Debris

B. Virginia's 2015 Coastal Needs Assessment and FY2016 - FY2020 Strategies

The Virginia CZM Program is focusing its efforts on the following assessment areas and issues between 2016 and 2020.

- Coastal Hazards
  - Shoreline Plan and Policy Development
  - Community Resiliency Plans
- Cumulative and Secondary Impacts
  - Chickahominy River: Leveraging Economic Benefits of Land Conservation
  - Working Waterfronts
- Ocean Resources
  - Stakeholder Coordination
  - Sand Management
  - Ocean Data Collection/Synthesis or Tools
  - Marine Debris

The Coastal Needs Assessment and Strategies portion of the Virginia CZM Program website provides detailed information on the Section 309 process as well as links to the 2011-15 and 2016-2020 documents. Pages 6 - 21 of the 2016-2020 Assessment and Strategies document provide a summary of accomplishments from the 2011-2015 Strategies.
www.deq.virginia.gov/Programs/CoastalZoneManagement/Funds,Initiatives,Projects/CoastalNeedsAssessment/CoastalNeedsAssessmentFY20112016.aspx

C. Virginia Marine Debris Reduction Plan

The Virginia CZM Program's Ocean Resources Strategy resulted in the development of the **Virginia Marine Debris Reduction Plan** – published in December of 2014. Virginia became the first state on the east coast to have a plan in place to address marine debris. The plan charts a course to reduce the amount of trash and marine debris from land-based and water-based sources in Virginia - for ecological, social and economic benefits - through: leadership, prevention, interception, innovation and removal. The complete plan and a summary publication are downloadable on the Virginia CZM Program website at http://www.deq.virginia.gov/Programs/CoastalZoneManagement/CZMIssuesInitiatives/MarineDebris.aspx. In March 2016, Virginia CZM Program funded and collaborated with its partners to conduct the 2nd Virginia Marine Debris Summit, including Clean Virginia Waterways of Longwood University, Virginia Institute of Marine Science - Sea Grant and Virginia Clean Marina Program, Virginia Aquarium, Keep Norfolk Beautiful, and the NOAA Marine Debris Program. The goal of the Summit was to bring together federal, state and local resource managers, scientists, community educators, non-profit members, citizens, and representatives of industry and commerce to share knowledge, evaluate progress, and craft next steps in the Virginia Marine Debris Reduction Plan. Among the ideas discussed were ways to integrate litter/trash programs with existing programs, like the MS4 permit process and the Chesapeake Bay cleanup efforts.

Having a Marine Debris Reduction Plan in place also will help Virginia meet one of its goals as a member of the Mid-Atlantic Regional Council on the Ocean (MARCO). One of MARCO's water quality issues of concern is marine debris. Read more about Virginia's role and work with MARCO at www.deq.virginia.gov/Programs/CoastalZoneManagement/CZMIssuesInitiatives/OceanPlanning/VirginiaOceanPlanning.aspx.

The Virginia CZM Program worked with the other Mid-Atlantic states to form the Mid-Atlantic Regional Council on the Ocean in 2009 (www.midatlanticocean.org) and joined with states, federal agencies and tribes to form the Mid-Atlantic Regional Planning Body in April 2013; www.boem.gov/Environmental-Stewardship/Mid-Atlantic-Regional-Planning-Body/index.aspx. In December 2016, the Mid-Atlantic RPB's **"Mid-Atlantic Ocean Action Plan"** was certified by the National Ocean Council **-** one of the nation's first two regional ocean plans in the U.S. The plan covers the ocean from Virginia to New York out to the 200-mile Exclusive Economic Zone. Its two main goals are to promote a healthy ocean ecosystem and sustainable human uses. Actions in the plan focus on better coordination and collaboration among federal agencies, states and tribes and the use of raw and synthesized data in the Mid-Atlantic Ocean Data Portal (http://portal.midatlanticocean.org). The plan can be viewed at http://www.boem.gov/Draft-MidA-Regional-Ocean-Action-Plan/.

For more information contact Laura McKay, Virginia CZM Program Manager – 804.698.4323 or Laura.McKay@deq.virginia.gov

5. Coastal Planning District Commissions

Virginia's eight coastal planning district commissions (PDCs) play an integral role in the Virginia Coastal Zone Management (CZM) Program. (See What is a "planning district commission") and all eight coastal PDCs meet quarterly with Virginia CZM staff. In addition, each PDC holds quarterly meetings for its local coastal resource managers. Coastal PDCs provide an important link between the state agencies and 87 localities that constitute Virginia's network of coastal resource managers. A representative from each PDC serves on the Virginia CZM Program's Coastal Policy Team and all eight coastal PDCs meet quarterly with Virginia CZM staff. In addition, each PDC holds quarterly meetings for its local coastal resource managers.

- Accomack-Northampton Planning District Commission
- Crater Planning District Commission
- Hampton Roads Planning District Commission
- Middle Peninsula Planning District Commission
- Northern Neck Planning District Commission
- Northern Virginia Regional Commission
- George Washington Regional Commission
- Richmond Regional Planning District Commission

The Virginia CZM Program supports each coastal PDC with an annual technical assistance grant and has provided assistance for a variety of regional and local coastal resource management projects sponsored by the PDCs.

With this funding support, Virginia's coastal PDCs have been instrumental in the planning and implementation of key water quality projects including:

Accomack-Northampton Planning District Commission

A. Southern Accomack County Ground Water Summit

The *Southern Accomack County Ground Water Summit* focused on communities within southern Accomack County including the towns of Onancock, Onley, Accomac, Wachapreague, Melfa, Keller, Painter, and Belle Haven. Presentations were made summarizing specific ground water conditions to different stakeholder groups including town and county governments and planning commissions, private citizens, and businesses.

The summit provided information on how past environments on the Eastern Shore have influenced public ground water supply with specific descriptions concerning Chesapeake Bay bolide impact, the southward progradation of the Susquehanna River and the Delmarva Peninsula and the influence of Carolina Bays on ground water. Additional explanation was given of past environments and how they affect water quality, resulting in high iron in some areas, sulfur smell in other areas, and hard carbonate waters, all on the Eastern Shore. The presentations gave insight into most issues surrounding the region’s sole source aquifers.

George Washington Regional Commission

A. Caroline County BMP Assessment, Tracking and Monitoring System

In partnership with University of Mary Washington, GWRC enhanced Caroline County's very basic BMP tracking system to provide more efficient organization of BMP site information, including map coordinates and BMP locations, site and property owner contact information, maintenance agreements, approved site plans and schematic drawings. The improved database enables the County to record and track the status of BMP inspections required under the Virginia Storm Water Management regulations and Chesapeake Bay Preservation Act to ensure that they are functioning as intended. The County can also more efficiently perform assessments of the existing conditions of these BMPs and determine which are in need of remedial action to restore their original water quality improvement design efficiencies.

B. Regional VSMP/Construction General Permit Roundtable

GWRC Storm Water Managers Technical Committee and Rappahannock River Basin Commission hosted a regional roundtable for local government staff to discuss the successes, problems and concerns with implementing Virginia's recently adopted VSMP and the revised Construction General Permits. In July of 2014 all localities were required to either adopt a VSMP (not optional for MS4 localities) or have the State take control of the local storm water program. The "rural" localities needed to indicate their desire to opt-in to the VSMP program by July 1 if they chose to operate the VSMP themselves. The Commonwealth's Construction General Permit was revised significantly as well. As with any new statewide program, there are many issues that need to be addressed as implementation is underway. The objective of the forum was to bring forth a better understanding of the complexities, issues and challenges that face the public and private sector in addressing storm water runoff in the Basin and to explore how the current mechanisms of the state's storm water programs operate. The summit attracted over 75 participants and concluded with the recommendation that the GWRC/RRBC Technical Committees continue to discuss and develop recommendations for improving the coordination and implementation of storm water programs within the Rappahannock Basin.

CHAPTER 7.7 CHESAPEAKE BAY PROGRAM INITIATIVES

The Commonwealth of Virginia has 120 miles of Atlantic Ocean coastline and approximately 2,200 square miles of estuary. The estuarine waters of Chesapeake Bay and its tidal tributaries are valued for their commercial fishing, wildlife, sporting, and recreational opportunities, as well as its commercial values in shipping and industry. In the late 1970's, adverse trends in water quality and living resources were noted and prompted creation of the Federal-Interstate Chesapeake Bay Program (CBP).

Through participation in the CBP and implementation of special state initiatives, Virginia maintains a firm commitment to rehabilitate and wisely manage its estuarine resources. This chapter provides an overview of the state's initiatives intended to restore and preserve the Chesapeake Bay and its tidal tributaries.

More about the Chesapeake Bay Program can be found on their website: http://www.chesapeakebay.net/.

Chesapeake Bay Program and the Bay TMDL

In 1983, Virginia, Maryland, Pennsylvania, the District of Columbia, the Environmental Protection Agency, and the Chesapeake Bay Commission signed the first Chesapeake Bay Agreement, formally initiating the restoration and protection of the Bay using a cooperative Chesapeake Bay Program approach. This approach established specific mechanisms for its coordination among the Program participants. Over the past decades several updated and new Bay Agreements, Executive Council Directives and pollution reduction strategies have been adopted by the Bay Program partners, generally refining and making the goals and objectives of the restoration effort more specific, establishing timelines and measurable outcomes to gauge progress.

On June 28, 2000, the Chesapeake Executive Council signed Chesapeake 2000 – a far-reaching agreement that has been guiding Maryland, Pennsylvania, Virginia, the District of Columbia, the Chesapeake Bay Commission, and the U.S. Environmental Protection Agency (EPA) in their combined efforts to restore and protect the Chesapeake Bay. Chesapeake 2000 outlined over 100 commitments in five program areas – Living Resource Protection and Restoration, Vital Habitat Protection and Restoration, Water Quality Protection and Restoration, Sound Land Use, and Stewardship and Community Engagement – detailing protection and restoration goals critical to the health of the Bay watershed. From pledges to increase riparian forest buffers, preserve additional tracts of land, restore oyster populations and protect wetlands, Chesapeake 2000 pushed improving water quality as the most critical element in the overall protection and restoration of the Bay and its tributaries.

On June 16, 2014, the Chesapeake Executive Council signed the Chesapeake Bay Watershed Agreement – an update to the Chesapeake 2000 agreement. Representatives from Maryland, Pennsylvania, Virginia, the District of Columbia, the Chesapeake Bay Commission, and the U.S. Environmental Protection Agency (EPA) reaffirmed their support of the partnership. The 2014 agreement recommits partners to the Bay watershed restoration effort and emphasizes the need for a strategic, cost-effective approach to watershed restoration and protection. New signatories include New York, West Virginia and Delaware; over 12 federal agencies have also committed to restoration and protection efforts. The 2014 Watershed Agreement outlined 10 goals for five program areas – Abundant Life, Clean Water, Climate Change, Conserved Lands, and Engaged Communities – including the development and implementation of management strategies for the outcomes supporting goals outlined in the Agreement.

Despite some reductions in pollution resulting from nutrient load reduction efforts, the Chesapeake Bay and most of its tidal tributaries have been placed on the "impaired waters" list due to non-attainment of water quality standards. Per Section 303(d) of the Clean Water Act, this action necessitated the development of a "total maximum daily load" (TMDL). Since 2005 DEQ and regulatory agencies across seven jurisdictions (Virginia, Maryland, Delaware, West Virginia, Pennsylvania, New York, and the District

of Columbia) have been actively involved with EPA in the development of this TMDL, the largest ever developed to date. The Chesapeake Bay TMDL, approved December 31, 2010 by EPA, is an aggregation of smaller TMDLs representing the 92 individual tidal segments (39 of which belong to Virginia) comprising the Bay and its tributaries. The TMDL sets Bay watershed annual limits of 185.9 million pounds for nitrogen (25% reduction), 12.5 million pounds of phosphorus (24% reduction), and 6.45 billion pounds of sediment (20% reduction). These limits are divided by jurisdiction and major river basin as determined by modeling, on-the-ground monitoring data, and peer-reviewed science. A goal has been set to put all pollution control measures in place by 2025, with 60% of actions being completed by 2017. Increased dissolved oxygen concentrations, improved water clarity and growth of submerged aquatic vegetation (SAV), and the reduction in the frequency and size of algal blooms (as measured by chlorophyll *a* concentrations) are among the anticipated outcomes in water quality from these actions. More about the Chesapeake Bay TMDL can be found here: http://www.epa.gov/reg3wapd/tmdl/ChesapeakeBay/tmdlexec.html.

In Virginia, the Department of Environmental Quality (DEQ) has primary responsibility for point source discharge issues, non-point source control programs, bringing together programs in the areas of surface and groundwater protection, waste management, and air pollution control. Other state and federal agencies that provide vital support include: Department of Conservation and Recreation, Game and Inland Fisheries, Forestry, Health, Marine Resources Commission, Agriculture and Consumer Services, the United States Geological Survey and the scientific community via agreements with the Virginia Institute of Marine Science, Old Dominion University and Virginia Commonwealth University.

Watershed Implementation Plan

Virginia's Watershed Implementation Plan (WIP) for the Bay TMDL is an evolution of Virginia's Tributary Strategies Program started in 2005. It was designed through a collaboration of agencies under the Secretary of Natural Resources, local and regional non-regulatory governmental bodies, concerned citizen groups, and the regulated community to accomplish the allocation goals set by the Bay TMDL. The first of three phases of the WIP establishes the authorities, actions, and control measures that will be implemented to achieve the non-point and point source TMDL allocations. It allocates basin-specific pollution loads to wastewater treatment plants, agriculture, forest, urban stormwater, septic, and air sources. It is anticipated that many of these allocations will be achieved through the enforcement of current and proposed regulations. Proposed tax credits and existing grant programs (such as Virginia's Water Quality Improvement Fund) will facilitate Best Management Practices (BMPs) and system upgrades that prevent and/or reduce nutrient and sediment pollution. Use of the existing Nutrient Credit Exchange program is also incorporated into the plan. Additionally, the WIP charts out a study designed to evaluate the numeric chlorophyll *a* standards used to determine nutrient impairment in the tidal portion of the James River. More information about Virginia's Phase II WIP can be found at the following website: http://www.deq.virginia.gov/Portals/0/DEQ/Water/TMDL/Baywip/vatmdlwipphase2.pdf. Virginia is currently preparing its Phase III WIP, which will include a more focused and sustainable local engagement effort and local strategies, as described here: http://www.deq.virginia.gov/Programs/Water/ChesapeakeBay/ChesapeakeBayTMDL/PhaseIIIWatershedImplementationPlanning.aspx. This planning is partially informed by the midpoint assessment – a review of the progress Virginia has made towards meeting the nutrient and sediment pollutant load reductions necessary for Bay restoration. Virginia reports on progress in the annual report on Chesapeake Bay and Virginia Waters Clean-Up Plan. The latest report is found at http://leg2.state.va.us/dls/h&sdocs.nsf/By+Year/RD4002016/$file/RD400.pdf.

Water Quality and Habitat Monitoring Initiatives

Chesapeake Bay Program

Monitoring is vital to understanding environmental problems, developing strategies for managing the Bay's resources, and assessing progress of management practices. The purpose of the Chesapeake Bay Program (CBP) Water Quality and Habitat Monitoring Program is to assess status and trends in

water quality and living resources throughout the Virginia portion of the Bay and its major tidal tributaries. Parameters monitored include those directly related to Water Quality Standards (e.g. dissolved oxygen, water clarity, chlorophyll *a,* etc.) as well as basic ecological health indicators such as primary productivity, nutrients, phytoplankton species, etc. A general description of Virginia's Chesapeake Bay monitoring program is:

- Water quality monitoring at 45 fixed stations on the Rappahannock, York and James Rivers;
- Water quality monitoring at 27 fixed stations in the Chesapeake Bay mainstem;
- Water quality monitoring and estimates of nutrient loading at stations on the James, Rappahannock, Mattaponi, Pamunkey, Shenandoah, Appomattox, Chickahominy and other smaller rivers throughout the Bay watershed;
- Monitoring of benthos communities in the Bay and its tributaries at 19 fixed stations and 100 random stations per year;
- Spatially and temporally intensive monitoring of selected water quality parameters on a rotating waterbody basis for 3-year periods.
- Annual aerial submerged aquatic vegetation surveys through-out the Bay and its tributaries.

Estuarine Probabilistic Monitoring Program (Coastal 2000)

A less extensive monitoring program which probabilistically samples all of VA's estuarine waters (including those outside the Bay watershed such as on the Atlantic coast of the Eastern Shore, Back Bay, and North Landing River) is the "National Coastal Assessment (NCA) Program", formerly known as the "Coastal 2000 Initiative". A detailed description of this program is provided in Chapter 3.2.

Habitat Restoration

The Bay Program partnership implements programs to restore critical habitats and tracks progress on an annual basis. These efforts not only restore habitat for wildlife and fisheries, but they also improve water quality. Since 2003, 173 acres of submerged aquatic vegetation were planted Bay-wide. Between 2010 and 2012, 5,503 acres of wetland were established Bay-wide. Since 1988, 2,576 miles of fish passage (primarily via dam removals) were restored Bay-wide. As of 2014, oyster restoration efforts have taken place in the Lynnhaven, Piankatank, and Lafayette Rivers. For more information on DEQ's role in coastal habitat restoration, see Chapter 7.5.

The 2014 Watershed Agreement included a Vital Habitats Goal to "restore, enhance and protect a network of land and water habitats to support fish and wildlife and to afford other public benefits, including water quality, recreational uses and scenic value across the watershed." Goal outcomes addressed the following areas of concern: wetlands, black duck population, stream health, brook trout population, fish passage, submerged aquatic vegetation, forest buffers, and urban tree canopy,

Toxics

The 1987 Chesapeake Bay Agreement committed signatories to develop, adopt and begin implementation of a basin-wide toxics strategy to achieve a reduction of toxic pollutants consistent with the Water Quality Act of 1987. Following the implementation of a multi-jurisdictional effort to define the nature, extent, and magnitude of toxics problems, the strategy was further strengthened with the adoption of the 1994 Basin-Wide Toxics Reduction and Prevention Strategy. The primary goal of the 1994 strategy was to have a "*Bay free of toxics by reducing and eliminating the input of chemical contaminants from all controllable sources to levels that result in no toxic or bioaccumulative impact on living resources that inhabit the Bay or on human health".*

Building upon progress achieved through the implementation of the 1994 Strategy, the Chesapeake Bay Program adopted a revised strategy in December 2000 known as the "Toxics 2000 Strategy". With the

retention of the 1994 goal, new objectives and commitments were developed and incorporated. The agreement made commitments to four goals: 1) prevent and reduce chemical contaminant inputs and eliminate toxic impacts on living resources that inhabit the Bay and rivers 2) eliminate all chemical contaminant-related fish consumption bans and advisories, 3) clean up contaminants in the sediment in the three most urbanized areas referred to as "Regions of Concern" (i.e., Baltimore Harbor, Anacostia River, Elizabeth River), and 4) sustain progress in the face of increasing population and expanded development within the watershed. Though much of the pollution control measures since 2000 have focused on nutrients and sediments, progress has been made on accomplishing these goals through the collaborative work of federal, jurisdictional, and non-governmental organizations. One success story is the removal of sediments contaminated by polyaromatic hydrocarbons and other pollutants from the Elizabeth River. The Toxic 2000 Strategy also includes commitments to the continued monitoring and reporting of toxics and their biological impacts. *Toxic Contaminants in the Chesapeake Bay and its Watershed: Extent and Severity of Occurrence and Potential Biological Effects* [1] provides the most recent overview of this work.

The 2014 Watershed Agreement established a Toxic Contaminants Goal to "ensure that the Bay and its rivers are free of the effects of toxic contaminants on living resources and human health." Goal outcomes included increased research efforts related to the impact and mitigation of toxic contaminants as well as improved policy and prevention efforts.

[1] *US Environmental Protection Agency, US Geological Survey, US Fish and Wildlife Service, 2012 Toxic Contaminants in the Chesapeake Bay and its Watershed: Extent and Severity of Occurrence and Potential Biological Effects, USEPA Chesapeake Bay Program Office, Annapolis, MD, December, 2012, 175 pages*

CHAPTER 7.8 WETLANDS ASSESSMENT AND PROGRAM INITIATIVES

Overview

Generally speaking, wetlands are lands transitioning between terrestrial and deep-water habitats where the water table is usually at or near the land surface or where the land is covered by shallow water (Cowardin *et al*., 1979). Virginia has many different types of wetlands, including salt marshes, estuarine wetlands along freshwater portions of tidal streams, interdunal swales, pocosins, palustrine wetlands in freshwater floodplains, freshwater swamps, bogs, fens, wet weadows, and isolated wetlands.

Wetlands may be defined in different ways with regard to jurisdictional issues, but all wetlands have in common a seasonal pattern of hydrology or continuous inundation, characteristic hydric soils, and vegetation adapted to growing under saturated condition. For example, the Wetlands Act of 1972 (Title 62.1 of the Code of Virginia) defines tidal wetlands for the purposes of protecting the resource and regulating development. As such, vegetated tidal wetlands are defined in the Act as "all land lying between and contiguous to mean low water and an elevation above mean low water equal to the factor 1.5 times the mean tide range at the site of the proposed project in the county, city or town in question," and on which are growing one or more of 37 specified species of wetlands vegetation. Non-vegetated wetlands are defined as all other lands between mean low water and mean high water. The Act does not include a definition for non-tidal wetlands, nor does it include all lands that are considered to be wetlands under federal law. The definition of wetlands contained in the DEQ's Virginia Water Protection Permit Program Regulation 9VAC25-210-10 *et seq*. parallels the federal definition of wetlands contained in Section 404 of the Clean Water Act: "Wetlands mean those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support and, under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas." Wetlands are part of State Waters per Section 62.1-44.3 of the Code of Virginia. State Waters means “all water, on the surface and under the ground, wholly or partially within or bordering the Commonwealth or within its jurisdiction, including wetlands.”

Wetlands occupy approximately four percent of Virginia’s land mass (Dahl, 1990). United States Fish and Wildlife Service National Wetlands Inventory mapping and research from state scientists have estimated that vegetated palustrine wetlands cover approximately 1,075,443 acres of Virginia; estuarine wetlands cover approximately 190,996 acres; lacustrine wetlands cover about 193 acres; and riverine wetlands cover about 380 acres (Hershner *et al*., 2000). Approximately 72 percent of the wetland areas in Virginia, including all the estuarine wetlands and most of the large nontidal palustrine wetlands, are in the Coastal Plain (Tiner and Finn, 1986). Approximately 22 percent of the wetlands in Virginia are in the Piedmont, and the remaining 6 percent are in the Appalachian Plateau (Tiner and Finn, 1986; Harlow and LeCain, 1991). Virginia has worked with local scientists to develop geographic information system-based (GIS) estimates of wetland acreage and wetland type by watershed, which can be used in cumulative wetland impact assessments, as discussed further in the Wetland Monitoring and Assessment section of this report.

Development activities in wetlands in Virginia are regulated by the U.S. Army Corps of Engineers (the Corps) through Section 404 of the Clean Water Act; by the Department of Environmental Quality, through the Virginia Water Protection Permit Program and Section 401 of the Clean Water Act; by the Virginia Marine Resources Commission (VMRC); and by local Wetland Boards through the Virginia Tidal Wetlands Act of 1972. For more information about wetlands, the historical development of the program, applicable laws/regulations, and permitting, see the VWP Permit Program web page at http://www.deq.virginia.gov/Programs/Water/WetlandsStreams.aspx.

Virginia has experienced losses of wetlands as a result of human-related development. In the 1780’s, wetlands covered about 1,849,000 acres (more than 7 percent) of Virginia (Dahl, 1990). By the mid-1980’s, when permits began to be required for most impacts to wetlands, about 1,075,000 wetland acres remained in Virginia – an overall loss of about 42 percent in 200 years (Dahl, 1990).

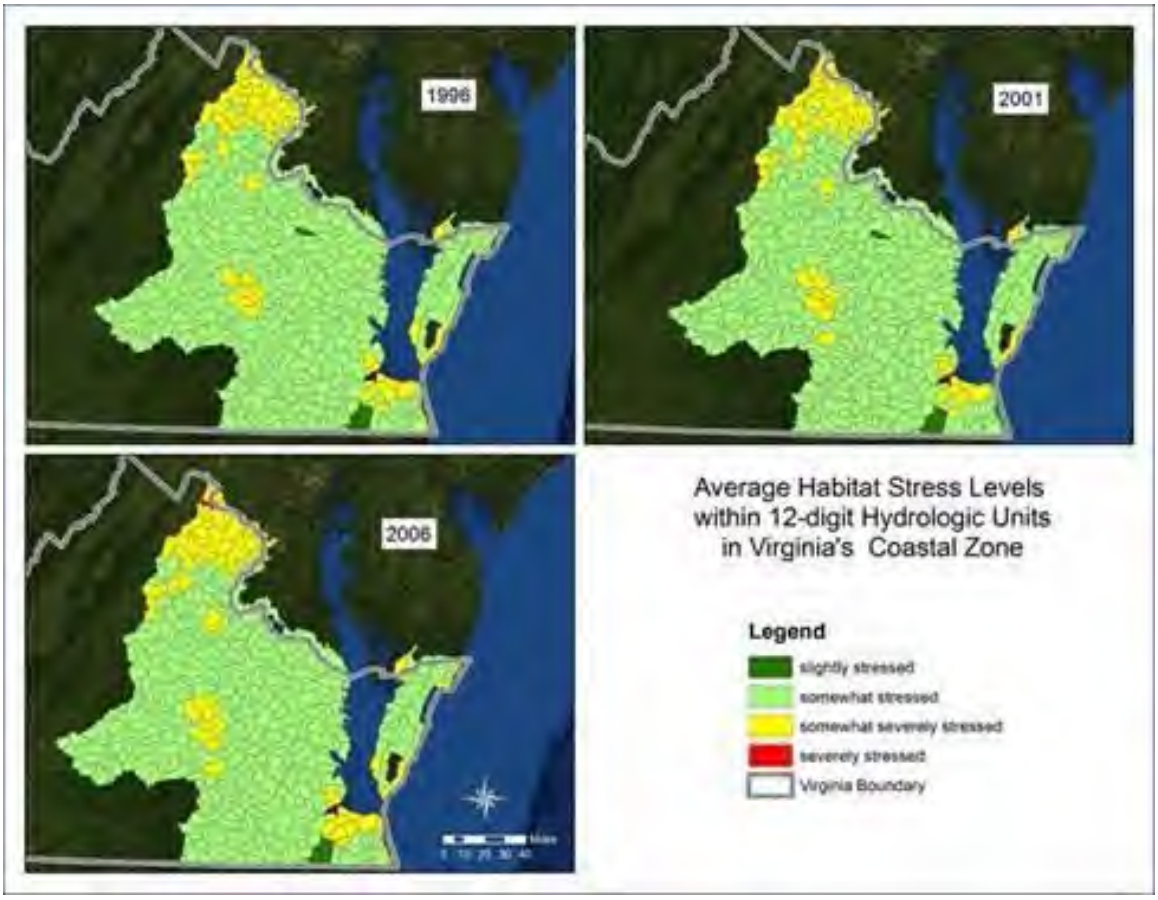
Agriculture and forestry, industrial and urban development, and recreation have led to the draining, dredging and ditching, filling, diking, and damming of wetlands in Virginia. According to a Chesapeake Bay Foundation fact sheet (2001), Virginia lost more than 770,000 acres of wetlands, for an average annual loss of 3,870 acres, during the 200-year period from the 1780s to the 1980s. From mid-1980 to the late 1990's, 80% of estimated losses of freshwater vegetated wetlands (mostly forested systems) occurred in the Coastal Plain. Wetland trends for the Norfolk/Hampton region of Virginia indicated a loss of about 4,800 acres of vegetated wetlands between 1982 and 1989-90 (Tiner and Foulis, 1994). During 1998 and 1999 alone, more than 2,500 acres of non-tidal wetlands in Virginia were ditched for development. The net loss of wetland areas has slowed since 2000 due to stricter laws, greater enforcement, and new mitigation strategies.

Wetland Monitoring and Assessment

Background

A key aspect of the Commonwealth of Virginia's nontidal wetlands program is ensuring that there is no net loss of wetland acreage and function through permitted impacts and a net gain in wetland resource through voluntary programs. To accomplish these goals, the Virginia Water Protection (VWP) Permit Program received grants from EPA in August 2003, October 2004, October 2006, October 2007, and October 2008 to determine the status of wetland resources in Virginia, in terms of location, extent, and overall quality of wetlands in each watershed. Using this information, the VWP Permit Program tracks changes in wetland acreage and functions, target certain watersheds, and help determine the effectiveness of compensatory mitigation replacing lost wetland acreage and function. As a first step, Virginia developed a long-term Wetland Monitoring and Assessment Strategy for wetland monitoring and assessment, including the goals and objectives of a monitoring and assessment program and a time frame for implementation. The strategy provides a framework for an ongoing assessment of the status of the Commonwealth's wetland resources and the success of both our wetland regulatory and voluntary programs. The end result of the ten-year strategy is expected to be the incorporation of wetland monitoring and assessment data into the Commonwealth's water quality monitoring programs.

Virginia has narrative water quality standards for all surface waters, including wetlands. The overall water quality for state waters is determined based on whether or not the condition of the waterbody being assessed allows citizens to safely enjoy the six designated uses of the water (aquatic life use, fish consumption use, swimming use, public water supply use, shellfish consumption use, and wildlife use), as described in the Virginia Water Quality Standards (9VAC25-260 et seq). Part of the above-referenced monitoring and assessment strategy includes 1) the evaluation of these designated uses for their applicability to a wetland's condition, and 2) the assessment of whether other designated uses of wetlands may apply. The strategy may also support the agency's goal of developing specific wetland quality standards as narrative use criteria.



The wetland monitoring and assessment strategy incorporates the EPA March 2003 "Elements of a Wetland Monitoring and Assessment Program Checklist" and the EPA May 2006 "Application of Elements of a State Water Monitoring and Assessment Program for Wetlands" (a supplement to the 2003 EPA document). The strategy uses a three-tiered census approach to wetlands assessment, using a suite of core and supplemental indicators, to assess whether or not a particular wetland is performing at a similar condition as an identified reference wetland. The first tier (Level 1 analysis) consists of a comprehensive coverage of all mapped wetlands using a GIS-based analysis of remotely sensed information. The second tier of assessment (Level 2) is intended for use in a statistically selected sub-sample of the watershed wetland population and involves a more sophisticated analysis of remotely sensed information and a site visit for verification and additional data collection. The third tier assessment (Level 3) is designed to specifically evaluate performance of functions in wetlands under varying degrees of stress, as indicated by the results of Levels I and II.

Since 2003, the overall wetland monitoring and assessment strategy has been to establish baseline conditions in various broad contexts, such as land use, watershed, and wetland type. The elements of the wetland monitoring and assessment program are listed in Table 7.8-1 below.

Table 7.8-1 Wetland Monitoring and Assessment Program Elements	
Monitoring Strategy	1. Establish baseline condition of nontidal wetlands by broad category scaleable from individual wetland to small watershed to physiographic province to entire State. 2. Guide management decisions regarding restoration, compensation, and regulation of wetlands.
Monitoring Objectives	1. Support regulatory decision-making. 2. Report wetland condition. 3. Guide policy development. 4. Evaluate cumulative impacts of wetland loss. 5. Evaluate wetland restoration and compensatory mitigation effectiveness.
Survey Design	Three-Tiered: Sample Frame = all NWI wetlands 1. Enhanced GIS analysis (census) – Level I (Model Development). 2. Probability-based sampling for field assessment of anthropogenic stressors – Level II (Model Calibration). 3. Intensive study of biological endpoints (birds, amphibians, water quality) along stressor gradient – Level III+ (Model Validation).
Assessment Indicators and Methods	1. Level I (Model Development): land use adjacent, within 200m, and within 1000m of wetland, wetland size, type, hydroperiod, proximity to other wetlands, road type, road density, and road alignment. 2. Level II (Model Calibration): field assessment of anthropogenic stressors within 30m of wetland assessment point and within 100m of wetland assessment point. 3. Level III (Model Validation): population and community structure metrics for birds and amphibians. Water quality modification metrics.
Quality Assurance	An EPA-approved Quality Management Plan coupled with the VIMS' Quality Assurance Plan used to prevent random and systematic errors. Techniques include direct electronic field data assimilation to prevent transcription error as well as random return site visits and redundant QA assessment loops.

Example of Results

Wetland condition scores for both habitat and water quality for the coastal plain showed shifts over a 10 year period from 1996 to 2006. Overall wetland habitat considered severely and somewhat severely stressed increased from 18.2% in 1996 to 21.2% in 2006 with a concurrent decrease in wetlands considered somewhat stressed and slightly stressed from 81.6% in 1996 to 78.8% in 2006. Wetlands with water quality condition considered severely and somewhat severely stressed increased from 33.1% in 1996 to 35.3% in 2006 with a concurrent decrease in wetlands considered somewhat stressed and slightly stressed from 66.9% in 1996 to 64.7% in 2006 (Table 8). Condition scores averaged by 12-digit HUC are shown for three years (1996, 2001, 2006) in Figure 7.8-1.

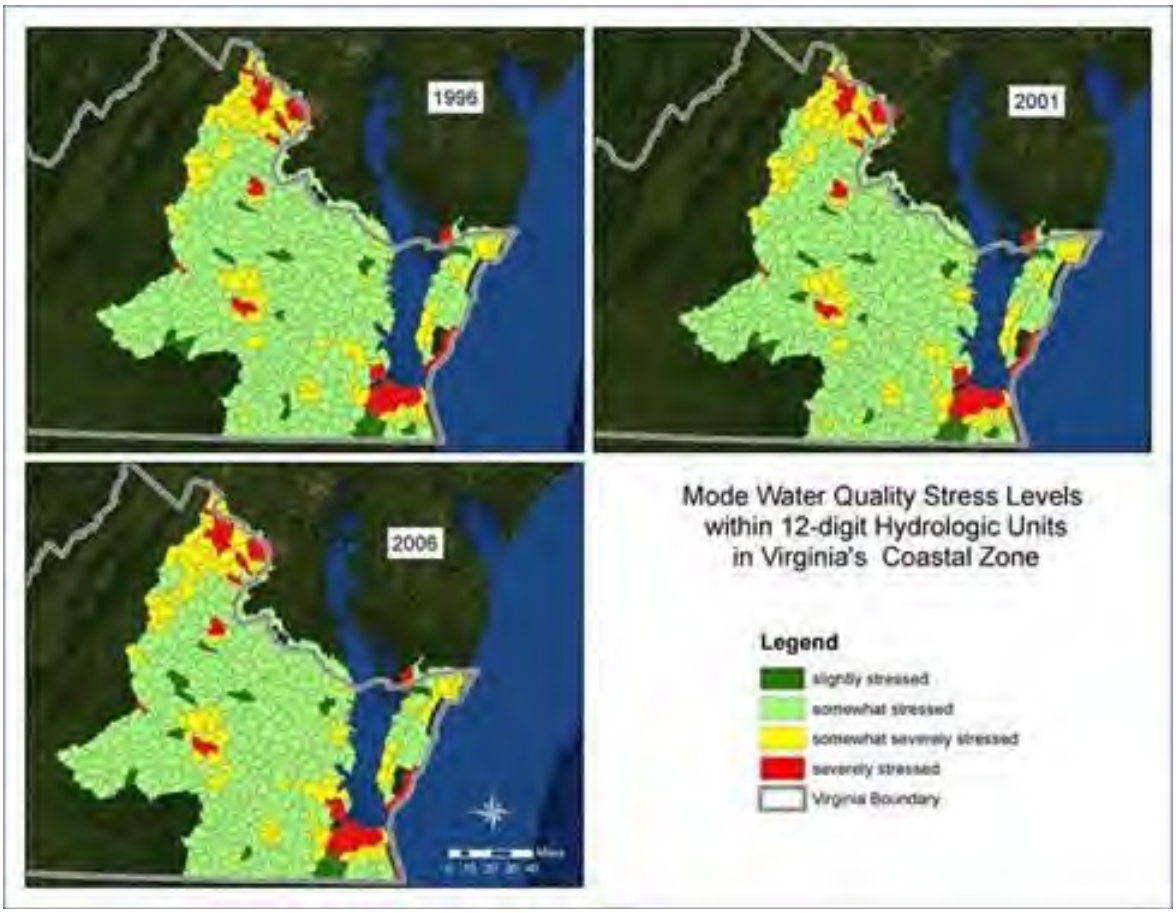


Figure 7.8-2. Wetland condition scores by 12-digit HUC for habitat ecosystem service and water quality ecosystem service in the coastal plain of Virginia for the years 1996, 2001, 2006.

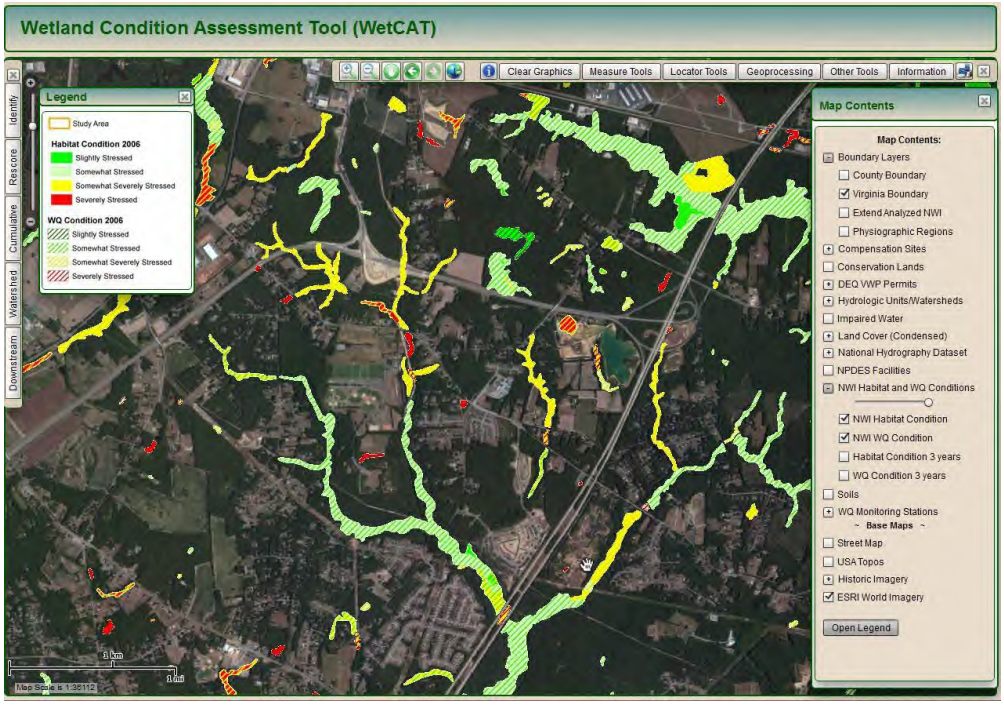
Current initiatives

DEQ's monitoring objectives are designed to support regulatory decision-making, allow reporting of wetland conditions, and provide information for policy development. Products from the wetlands monitoring and assessment strategy directly support Goal 4 of EPA's Strategic Plan to provide *"…additional focus on assessment of wetland condition"* and the National Priority of "*wetlands monitoring and assessment".* Table 7.8-2 provides an overview of the strategy's milestones and the status of each.

Table 7.8-2: Long-term wetlands field assessment strategy for Virginia

Phase 1	Oct. 2003	Begin Level I assessment for Virginia.	Complete
	Dec. 2004	Begin Level II site assessment of Coastal Plain wetlands.	Complete
	Dec. 2005	Complete Level I assessment of Virginia, Complete Level II site assessment of Coastal Plain, Develop protocol for Level III assessment for Coastal Plain physiographic province.	Complete
Phase 2	Dec. 2005	Begin Level II site assessment of Piedmont physiographic province.	Complete
	Sept. 2007	Complete Level II site assessment of Piedmont. Begin Level III sampling for coastal plain sites.	Complete



Phase 3	Oct. 2007 – Sept. 2008	Complete enhanced wetland site selection for Ridge and Valley Level II site assessment using a protocol for probable wetlands location. Complete Level II site assessment for Ridge and Valley physiographic provinces. Continue Level III sampling for Coastal Plain.	Complete
Phase 4	Oct. 2008 – Sept 2010	Begin Level III (model validation) sampling for Piedmont, and Ridge and Valley. Begin Level II re-sample coastal plain subset for calibration.	Complete
Phase 5	Oct. 2010	Begin Level I re-sample of Virginia for trends analysis.	Complete
Phase 6	Oct. 2010	Development of a Wetland Program Comprehensive Plan, refinement of our environmental database, and continued development of the wetlands monitoring and assessment program.	Complete
Phase 7	Oct. 2011 – Dec. 2014	Collaborate with VDOT to incorporate linear transportation projects into the wetland data viewer, potentially review and update the monitoring and assessment strategy to incorporate completed tasks and re-evaluate the direction of the strategy. Continued re-calibration of the assessment model.	Complete
Phase 8	Oct. 2014	New data collection equipment have been distributed to DEQ monitoring staff and the training field staff is complete. Development and testing of new protocols for DEQ field staff that provides for integrated data collection and quality assurance in support of the recalibration effort and non-mapped NWI wetland identification is ongoing. Continuing the model recalibration and developing additional datasets for WetCAT.	Ongoing

The following summarizes some key results of the strategy effort to date:

- Based on the model validation (Level 3) for the Piedmont and Ridge & Valley physiographic provinces of Virginia, and the re-calibration of the Coastal Plain, the relative stressor frequency has remained similar in the coastal plain between 2004 and 2010 with some slight increases in eroding banks/slopes and sediment deposits/plumes but with a decrease in 2010 of potential non-point discharge toxics/nutrients. Re-calibration of surrounding landcover and stressors shows that the landcover classes remain valid for condition assessment scoring. All landcover types identified in the earlier assessment as having significant relationship to the ecosystem endpoints of habitat and water quality continue to have significant relationships with the identified onsite stressors.
- DEQ and VIMS staff have designed and implemented procedures to facilitate the routine application of inventory and monitoring data in permitting decisions. A web-based delivery of monitoring data and a prototype tool for assessment of wetlands that are not part of the NWI database has been developed. Both of these tools were designed to assist DEQ wetland project managers by providing desktop access to information on wetland resources throughout the Commonwealth. Additional work was needed to improve the user interface such that cumulative impacts may be assessed and compensation opportunities may be identified.
- A pilot study that included input from state and federal personnel on the use of the wetland data viewer was conducted in 2011. We anticipate that these data may be used by local governments (for comprehensive planning process and zoning), regulatory agencies (for cumulative impact analysis), researchers (for developing new studies and research questions), and the general public (for wetland and watershed awareness).

- Virginia continues to develop a baseline data set, documenting current conditions and the general quality of wetlands throughout the state to determine whether existing wetland conditions are affecting wetland functions and values. Using a Geographic Information System (GIS), a baseline map has been developed by overlaying wetlands, as depicted on National Wetland Inventory (NWI) maps and other data sources listed previously, and a wetland quality indicator developed from the use of a stressor checklist tool and wetland landscape position. This information can be reported in the context of wetland types, land use, landscape position, or by watersheds, depending upon the information needed. Preliminary data and mapping has been uploaded to a web-access server, hosted by the Virginia Institute of Marine Science (VIMS), and once made public, these data will allow anyone to search the data base by several parameters (preview in Figure 7.7-3). The data viewer has been refined to include tools for assessing linear projects, and GIS mitigation bank data from the Regulatory In-lieu fee and Bank Information Tracking System (RIBITS) has been incorporated.

Figure 7.8-3. GIS-based Wetland data viewer

- Continue development of both a training manual as a reference for users, and a training event that can be self-paced. This information and all other accomplishments completed since 2005 will be incorporated into an updated Monitoring and Assessment Strategy. The project will increase the understanding of a wetland's condition and improve evaluation of environmental impacts to wetlands during permit reviews as part of Virginia's regulatory program.

Future actions

DEQ is currently conducting orthophotography of the entire Commonwealth of Virginia through funding from NOAA. This data will be imported into WetCAT once completed. As additional data are collected, Virginia will use this sequential survey information to look at changes in wetland quantity and quality over time. This temporal analysis will be accomplished by continuing to refine the wetland database with information on wetland losses and gains in each watershed using the permit tracking database, as well as periodically conducting wetland quality assessments in select watersheds to make inferences on wetland conditions. This in turn will allow for management decisions to be made that could provide additional protections for watersheds experiencing significant declines in wetland quantity and/or quality. For example, monitoring information could be used to identify exceptional value wetlands that should have greater protection within the context of permitting programs and to identify good candidates for targeting wetland restoration projects.

In order to generate the type of site specific guidance and recommendations that DEQ wetland project managers indicate would be most useful, VIMS developed and tested some new analytical protocols modeled on procedures developed by VIMS under previous EPA grants. Future success will be measured by an increasing trend in the statistically-reliable Level I protocol that is used by wetland managers to assess cumulative wetland impacts and wetland and watershed restoration opportunities. By having a statistically-validated tool that measures wetland quality as a function of habitat and water quality parameters, our permit staff will be able to make better permit decisions relative to potential cumulative impacts. Further, we will also be able to measure how well we are protecting the function of our more vulnerable wetlands (i.e. isolated wetlands, vernal pools, white cedar swamps) by comparing the condition of wetland habitat and water quality parameters, as a function of the assessment scoring over time. The overall outcome of this continued focus on wetland monitoring and assessment will be better protection of wetlands and more definitive and defensible information on wetland condition over time, and documentation of how we are achieving no net loss of wetland acreage and function in Virginia.

As State Water Control Law (SWCL) and VWP Permit Program regulations require compensation for unavoidable, permanent impacts to surface waters that are sufficient to achieve no net loss of existing wetland acreage and function and no net loss of function in all surface waters (See, § 62.1-44.15:21 and 9VAC25-210-80 (C)), the data collected will also be used in conjunction with other water monitoring data to evaluate the effectiveness of wetland protection programs in terms of meeting the goal of no net loss of wetland acreage and functions. This will be accomplished through Section 305(b) reporting, and will include a determination of whether the wetland regulatory program is attaining this goal. In addition, wetland monitoring information can be used within the context of the following programs to address additional management measures: Section 319 (nonpoint source control), Section 314 (Clean Lakes), Section 303(d) Total Maximum Daily Loads (TMDLs), Section 402 (NPDES permits), and water quality standards modifications.

CHAPTER 7.9 DEQ WATER QUALITY REGIONAL INITIATIVES

For more information about DEQ's regional offices, please visit
http://www.deq.virginia.gov/Locations.aspx

VALLEY REGIONAL OFFICE (VRO)

South River Mercury.

Mercury was used in a manufacturing process at the DuPont plant in Waynesboro, VA from 1929-1950. Mercury losses and resulting contamination to the river and floodplain from that process resulted in a legacy problem that continues today. In a 1984 settlement between DuPont and the State Water Control Board, a fund was established to support monitoring of water, sediments, and fish tissue in the river system for a projected 100-year period. More recently, in 2006, DEQ established a full-time position in the Valley Regional Office to focus on this serious environmental issue. Specific activities in this program area that occurred during 2014-2015 are outlined below.

a) **Water Sample Collection and Analysis for Mercury in the South River and South Fork Shenandoah River, Virginia.** This monitoring project focuses on water column concentrations of dissolved and total mercury in the South River and South Fork Shenandoah River. Monitoring through the 1990s rarely detected measurable amounts of mercury in water, due to analytical constraints. With the development of more sensitive techniques ("clean" metals sampling and analyses) during the 1990s, quantifiable levels are now routinely recorded. Since 2001, DEQ staff has collected total and dissolved mercury samples from multiple sites on the South River and South Fork Shenandoah River on a bimonthly frequency.

b) **South River Science Team.** DEQ staff members continue to coordinate with members of the South River Science Team on a number of surveys and studies in which data are gathered for water, sediments, floodplain soils, and biota in and along the South River. The South River Science team is comprised of representatives from industry, academic institutions, state and federal agencies, environmental groups and independent researchers. This group meets quarterly to coordinate efforts, collaborate on future work, and communicate results. Ongoing studies address mercury source identification, fate and transport, methylation processes, and ecological processes. Information on the activities of the South River Science Team can be found at http://www.southriverscienceteam.org/.

c) **Natural Resources Damage Assessment (NRDA) for South River and South Fork Shenandoah River.** DEQ is working with other state partners (as the state trustee) and the US Fish & Wildlife Service (as federal trustee) to continue assessment of damages to aquatic and terrestrial life in and along these rivers. Studies by South River Science Team partners and contractors will serve as the basis for damage assessment and will also help identify opportunities for restoration and mitigation. Final settlement, expected in 2016 or 2017, is intended to address restoration of numerous resources and services, including fish, birds, amphibians, and recreational fishing.

BLUE RIDGE REGIONAL OFFICE – LYNCHBURG (BRRO-L)

Total Maximum Daily Load (TMDL) Studies

There are currently three (3). TMDL studies being conducted or been completed by BRRO-L water staff. There are currently two (2) Implementation Plans either being conducted or have been completed in BRRO-L over the past two years. The projects are listed in detail below.

Kits Creek
The TMDL study was completed and approved by EPA and is awaiting approval from the Virginia SWCB. The project addressed benthic impairment in Kits Creek. A public meeting was held to discuss the TMDL process and the sources of sediment and phosphorus unique to Kits Creek watershed.

Kerr Reservoir Tributaries
The TMDL study is currently underway with a public comment period on the draft report ending February 27, 2017. The project addresses bacteria impairments in several tributaries to Kerr Reservoir including, Little Bluestone Creek, Bluestone Creek, Allen Creek, unnamed tributary, Allen Creek, Cotton Creek, Kettles Creek, Smith Creek, and Lizard Creek. A public meeting was held to discuss the TMDL process and the sources of bacteria unique to the Kerr reservoir Tributaries.

James River Basin
The TMDL re-development study was started in 2013. The project addresses bacteria impairments in the James River as well as several tributaries including, Ivy Creek, Tomahawk Creek, Burton Creek, UT Burton Creek, Judith Creek, Fishing Creek, Blackwater Creek, beaver Creek, Harris Creek, Dreaming Creek, Opossum Creek, Williams Run, Graham Creek, and Pedlar River. A public meeting was held to discuss the TMDL process and the sources of bacteria unique to the James River basin. DEQ is currently formulating responses to public comments received.

Ash Camp Creek and Twittys Creek Implementation Plan
The project addressed benthic impairments in Ash Camp Creek and Twittys Creek watershed. A public meeting was held to discuss the Implementation Plan process and the sources of bacteria unique to the watershed. The final report was approved by the Virginia SWCB on 02/25/2016.

Banister River and Winn Creek Implementation Plan
The project addressed bacteria impairments in Banister River and Winn Creek Watershed. A public meeting was held to discuss the Implementation Plan process and the sources of bacteria unique to the watershed. . The final report was approved by the Virginia SWCB on 02/25/2016.

Dan River Watershed Implementation Plan
The project addresses bacteria impairments in the Dan River Watershed, including the Dan River, Birch Creek, Byrds Branch, Doubles Creek, Fall Creek and Sandy Creek. The project start date is February 2017.

Environmental Pollution Response

Dan River Coal Ash Spill
On February 2, 2014 a broken stormwater pipe beneath a Duke Energy coal ash retention pond located next to the Dan River near Eden, NC was reported. Approximately 38,000 tons of coal ash spilled into the Dan River. Coal ash contains heavy metals and can be harmful to human health. Monitoring for metals in the water and sediment at eight Dan River sites and two Kerr Reservoir sites began in February 2014 and continued monthly through 2016. Bi-monthly monitoring has begun in 2017. In addition, two boatable probabilistic sites on the Dan River will be sampled in the spring and fall on an annual basis for benthic macroinvertebrates, fish, algae, water chemistry, and habitat quality.

Public Outreach

Watershed Educator Institute
Regional Biologist, Kelly Hazlegrove, provided an overview of DEQ biomonitoring and assessment to the Watershed Educator Institute held in Charlottesville, Virginia on April 12, 2016. The Watershed Educators Institute is a series of one and two day workshops offered from October 2015 through June 2016 for those desiring to be formally recognized as leaders in watershed education in the Commonwealth of Virginia.

Franklin County Fair

Monitoring and TMDL staff from BRRO-L presented a storm water education program to over 300 5th grade students on September 16, 2016. The table allows for a hand on demonstration of the impacts of storm water on forest land, farm land and urban settings.

BLUE RIDGE REGIONAL OFFICE (BRRO-ROANOKE)

TMDL and Implementation Planning Activities in the BRRO-Roanoke

BRRO-Roanoke's TMDL staff assisted in the completion of Implementation Plans on the Upper Roanoke River watershed, Crab Creek, and Smith and Mayo Rivers. DCR was the lead agency on all of the aforementioned TMDL Implementation Plans except for Roanoke River and Crab Creek.

BRRO-Roanoke TMDL staff took the lead on the Implementation Plan for the Upper Roanoke River. The kick-off meeting for this project occurred in the form of a watershed open house featuring a series of presentations and informational booths for visitors to peruse. Due to the size of the watershed, implementation plan development was divided into two parts. Throughout 2013 and 2014, the Part I government, residential, agricultural, and business working groups met two times to discuss and select appropriate best management practices. Part I and Part II Implementation Planning continued beyond 2014.

In addition, BRRO-Roanoke TMDL Staff led Implementation Plan development for Pigg River watershed, and Little River Watershed TMDL and Implementation Plan, and ultimately the Crab Creek Implementation Plan. DCR and local stakeholders like the Blue Ridge Soil and Water Conservation District and Skyline Soil and Water Conservation District assisted with the projects. A watershed tour, agricultural and residential working group meetings, and public meetings encouraged public involvement in the projects. Presentations about the Pigg River Watershed Implementation Plan were given at the Franklin County Cattlemen's Association and the Roanoke River Currents Conference.

Special studies related to TMDLs included water column PCB sampling in the Roanoke River and New River watersheds, diurnal dissolved oxygen studies in the Smith River and Jackson River (Smith River included temperature data). In addition, TMDL staff made presentations to permittees in the Roanoke River regarding PCBs and PCB TMDL development.

BRRO-Roanoke Community Involvement

The BRRO-Roanoke Water Monitoring Group (monitoring, TMDL, and assessment staff) participated in numerous outreach events during 2009-2014. Staff taught area students and teachers about biological monitoring at events such as the Clean Valley Council's Earth Summit, Fall Waterways Cleanup, Smith Mountain Lake State Park's Junior Rangers program, Bedford Elementary "Camp Bees" day camp, and Roanoke area Cub Scouts at "Bug Scouts" day camps. The group had displays at Earth Day Celebration, 18th Annual Salem Fall Home Show, and Philpott Reservoir Environmental Expo. Staff also made presentations on water pollution, monitoring, and restoration at the following events: Friends of Claytor Lake meetings, Roanoke River Currents Conference, Smith River Trout Unlimited Chapter meeting, Southern Rivers Grant Project leaders gathering in Radford, 2012 Citizens Stormwater Committee Meeting, National Water Quality Monitoring Conference (Cincinnati, OH), Jackson River Preservation Association meetings, Isaak Walton League (Covington-Alleghany Chapter) meetings, meetings with Roanoke City Stormwater staff, and a Radford University Environmental Regulations class. DEQ hosted a booth at the Christiansburg High School Environmental Expo with information about water quality monitoring, biomonitoring and watershed stewardship.

BRRO-Roanoke Water Permitting, Waste and TMDL staff partnered with the Western Virginia Water Authority and worked with local Girl Scout troops to educate them about environmental issues. The girls learned about aquatic insects, water quality monitoring, watersheds and landfills. They collected water

quality data including pH, dissolved oxygen, and turbidity from Carvins Cove Reservoir. Troops also toured the water treatment plant in Roanoke.

Regional Monitoring Networks (RMNs) to Detect Changing Baselines in Freshwater Wadeable Streams

The United States Environmental Protection Agency (U.S. EPA) is working with its regional offices, states, tribes, and other entities to establish Regional Monitoring Networks (RMNs). The RMNs will help EPA and their partners collect current, baseline biological, thermal, and hydrologic data from freshwater wadeable streams. This information will be used to help quantify and detect long-term changes in conditions of high-quality streams. Project discussion began in 2013 with data collection beginning in 2014 and is ongoing. DEQ monitoring staff coordinates and conducts deployment and maintenance of temperature monitoring equipment.

Stream Flow Modification Monitoring

In 2013 and 2014, DEQ water monitoring staff began using Biological Monitoring (benthic macroinvertebrates and fish) and streamflow measurements to determine the ecological impacts of stream flow interruption by a small hydropower facility. This effort began as a result of complaints made to DEQ by downstream landowners and ultimately included site visits by multiple state agencies. Biologists collected and analyzed samples Spring and Fall of 2013 and 2014. Due to above-normal precipitation resulting in higher than normal flows in addition to maintenance on the hydropower facilities yielding less stream flow interruptions, the sampling effort will continue beyond 2014.

Stressor Identification in Virginia

BRRO and SWRO led an effort to improve the stressor identification process for benthic macroinvertebrate community (aquatic life use) impairments in the Commonwealth. The DEQ assesses aquatic invertebrate communities in order to evaluate whether or not Virginia's aquatic life use standard is being met. The root cause of an aquatic community shift is rarely obvious even though changes in the composition and/or abundance of the benthic macroinvertebrate community are distinct. DEQ utilizes EPA's recommended method, stressor analysis, to systematically characterize the cause of an aquatic community shift. The goal of the stressor analysis process is to apply a weight-of-evidence approach to define a/the most probable stressor(s) that explain(s) the shift in the benthic macroinvertebrate community. Aquatic community stressors encompass a wide array of parameters that have varying degrees of synergistic interactions, further complicating the stressor analysis process. Recognizing these challenges, stressor thresholds were developed utilizing ten years of data collected through DEQ's Freshwater Probabilistic Monitoring Program. Stressor thresholds are concentration/measured ranges linked to varying levels of stress to aquatic life that present context for stressor analyses reviewers and developers to evaluate water quality datasets and relate them to aquatic community outcomes. Statewide, ecoregion-, basin-, and stream order-specific context is presented in relation to the following common aquatic stressors: dissolved oxygen, pH, total phosphorus, total nitrogen, ionic strength (specific conductivity, TDS, and dissolved sulfate, chloride, sodium, and potassium), dissolved metals cumulative criterion unit, total habitat and relative bed stability. Specifically, thresholds ranging from no stress to aquatic life to high probability of stress aquatic life were developed and integrated into a web-based application for better understanding stressors.

Livability Initiatives

The Livability Initiatives provided multiple forums for residents to discuss housing, transportation, energy, natural resource, economic development, community health, and arts and cultural heritage factors that affect quality of life now and in the future. BRRO-Roanoke staff participated in Livability Initiative working groups in both the Roanoke and New River Valleys.

Jackson River Restoration and the Gathright Dam Water Control Plan

The Virginia Department of Environmental Quality's monitoring and assessment data and Jackson River benthic Total Maximum Daily Load (TMDL) development (DEQ 2010) has documented that low flow conditions in the fall represent the most stressed water quality conditions in the Jackson River. The Jackson River benthic TMDL study established nitrogen and phosphorous reduction targets in the Jackson River and called for restoring natural flow variability during the growing season (defined in the TMDL study as June 1st to October 31st). To assess flow variability impacts on water quality habitat and biology, DEQ asked the U.S. Army Corps of Engineers (ACE) to perform a 216 study that could result in permanent flow modifications in the Jackson River. The 216 Study was later changed to the Gathright Dam Water Control Plan. As part of the study and later the plan, the ACE performed test pulses during the following dates: August 17, 2010, September 28, 2011, and October 3, 2012. In 2010 thru 2014, DEQ collected an extensive suite of field data, water chemistry, habitat, and biological parameters in order to document baseline conditions and evaluate effects of the test pulses. DEQ is committed to extensive water quality monitoring in the Jackson River throughout the development of the Water Control Plan project and during the implementation of the recommended hydrologic changes. DEQ published the following reports which summarize existing water quality conditions and document results of the pulse events: *Characterization of 2010 Base Flow and Pulse Flow Water Quality in the Jackson River and Characterization of Jackson River Base Flow* and *Pulse Flow Water Quality: 2011 and 2012*. DEQ continues to monitor and evaluate water quality on the Jackson River.

PCB Source Investigations in the New River VDH Fish Consumption Advisory Area

From 2002 – 2004, an intense search for PCB sources was conducted in the New River watershed from Claytor Lake Dam to the Virginia-West Virginia State line near Glen Lyn. The investigation involved extensive review of VA DEQ agency records, interviews of local officials, citizens, industry representatives, and information provided by the New River PCB Source Study Citizen's Committee. Based on these interviews and follow-up onsite inspections, DEQ teams sampled soil and sediment from multiple areas in the New River Valley in the fall of 2003. The investigation incorporated approximately 50 sites of sediment and soil samples. DEQ initiated additional source investigation and pre-TMDL PCB monitoring in 2010 and continues to collect fish tissue, sediment and water column PCB data.

James River Fishkill Monitoring

During the spring and summer periods of 2007 – 2010, BRRO-Roanoke staff has assisted with the investigation of fish kills of unknown causes in the upper James River system. Predominantly smallmouth bass and sunfish are the affected species and have been observed with skin lesions and other health problems during the spring and early summer. During 2007 staff monitored and confirmed citizen reports of distressed and dead fish in the James River, monitored environmental conditions and assisted VDGIF biologists with fish collection for health analyses by USGS and university scientists. In 2008, staff continued to track citizen reports and collected multiple parameters (physical/environmental conditions, metals, organics, nutrients, and pesticides) on the James River and a reference site on the New River, as well as assisted with the collection of fish during pre-kill, within kill, and post-kill periods on both rivers. During spring and summer 2009 and 2010, staff collected weekly bacteria samples for Aeromonas salmonicida at ten stations on the upper James River and several tributaries. Staff also assisted with fish collection on the James River and tributaries and deployed temperature loggers at multiple locations to monitor daily water temperatures.

Mudlick Creek Stream Restoration Project

BRRO-Roanoke water monitoring and VWP staff assisted Roanoke County with a stream restoration project at Garst Mill Park from 2007 to 2009. Pre-restoration activity included monitoring the benthic macroinvertebrate community, monitoring turbidity during storm events, and measuring stream bank erosion in several sections of Mudlick Creek. Staff also provided technical guidance with restoration and design plans for County officials, DCR staff, and consultants that produced the design and supervised the project. Staff attended informational meetings held at the park to inform citizens of the project and its benefits to water quality. Post-restoration monitoring will include assisting the county with biological monitoring bank erosion surveys.

SOUTHWEST REGIONAL OFFICE (SWRO)

Coeburn-Norton-Wise Regional Wastewater Treatment Plant

Additional hydraulic capacity was created within the existing WWTP without building additional secondary treatment structures. The existing site is built out and the ability to increase hydraulic capacity via typical methods, i.e., build new tanks and increase volume, was not an available option. Hydraulic capacity was increased from 5.0 MGD to 6.5 MGD by improving the existing treatment scheme, particularly the secondary treatment process, and by adding tertiary filtration. Sludge processes were improved and capacity increased via covered tanks and heat addition to speed up the aerobic digestion process. The WWTP reliability was also improved through the addition of an emergency generator. Additionally, the WWTP upgrade included a septage receiving station and treatment unit that enables the CNWRWTA to accept septage from on-site systems throughout the region, and gives septic haulers a place to legally dispose of septic tank wastewater. The total project cost was approximately $15,000,000.00 and should serve the area for the next 20-25 years.

This project was unique because CNW serves four communities who own capacity in the regional WWTP. CNW does not collect wastewater, but only transports and treats. Each member community has a unique collection system that they are responsible for. CNW does not have any effective regulatory authority over the communities' systems. Each system is subject to I/I and flow to the WWTP reflects impact due to rainfall-induced inflow/infiltration. As a result, CNW was experiencing permit violations due to hydraulic overloading, especially during significant precipitation events.

Tazewell County PSA—Tazewell to Divides Collection System (Phase I)

Construction has begun on a force main/gravity sewer system from Tazewell to the landfill near the Divides. This is Phase I of a multi-phase project and will provide the spine or interceptor that will initially take leachate flow from the landfill site and transport it to the Town of Tazewell collection system with ultimate treatment at the Tazewell WWTP. Subsequent phases will provide collection systems to built-up areas along Route 460 between Tazewell and the Divides. Currently the landfill leachate is trucked to area wastewater treatment plants for treatment. Realization of this project will eliminate the expense of trucking and the dangers associated with trucking along routes where T&E waters are present, and also significantly eliminate potential for leachate to migrate to the headwaters of the North Fork Clinch River. The project cost is $4,678,659.

NORTHERN REGIONAL OFFICE (NRO)

The summary of regional initiatives focuses on updates and/or new activities since the publication of the 2014 Integrated Report. Accordingly, updates are primarily highlighted for 2013 and 2014.

Biological Monitoring:

<u>Probabilistic Biomonitoring and Chemical Monitoring Program in Virginia Non-Tidal Streams</u>

NRO has participated in DEQ's Probabilistic Monitoring Program for non-tidal streams since its inception in the spring of 2000. This program consists of three sampling components: a thorough examination of the benthic macroinvertebrate community utilizing the EPA's Rapid Bioassessment Protocols, sampling a full suite of water chemical parameters, and a physical habitat evaluation at each station. The stations are biologically and chemically sampled twice a year, once each in the spring and fall, while a single, extensive, physical habitat evaluation is conducted in the fall. In 2013, NRO sampled eight probabilistic monitoring stations and another nine stations in 2014.

Genus Virginia Stream Condition Index (VSCI) and Coastal Plain Macroinvertebrate Index (CPMI) Development Sampling

NRO has been participating since 2009 through 2014 in the development of both a family-level and a genus-level benthic macroinvertebrate index to refine the assessment of Coastal Plain and Southeastern Plains, defined-channel streams. The monitoring effort included biologically and chemically sampling in at both excellent-condition and stressed-condition streams.

Citizen Monitoring Requests:

Ambient Monitoring

In 2013, citizens of Virginia requested that 3 streams (Wolftrap Run, Bull Run and an Unnamed tributary to the Occoquan River) be monitored by NRO for chemical parameters, of which all 3 were honored/ Monitoring of two streams of the three requested streams (Wolftrap Run and Bull Run) continued to be sampled in 2014. No requests from citizens for monitoring of chemical parameters were received in 2014.

Biological Monitoring

In 2013, citizens of Virginia requested that 3 streams (Ballywhack aka Tanyard Creek, Bull Run, and Wolf Trap Run/Old Courthouse Branch) be biologically monitored by NRO, of which all 3 were honored. Similarly, 4 streams (South Fork Catoctin, Sycolin Creek, Goose Creek and Bull Run) were requested by citizens in 2014, of which DEQ was able to honor the request for 2 (Goose Creek and Bull Run) out of the 4 streams. All of the locations were sampled twice in one year, once each in the spring and the fall.

Special Studies:

Quantico Creek

NRO initiated a special study monitoring program in 2014 in the tidal embayment and the free-flowing, riverine portion of Quantico Creek. This special study was initiated as a follow-up from the aquatic life use impairment first listed in 2001 for a portion of the Quantico Creek embayment, The study involved collecting metals data from sediment and water samples at six monitoring stations in the watershed.

Potomac Creek

NRO conducted follow-up sediment sampling in Potomac Creek in 2014 due to elevated concentrations of various constituents in sediment from the Estuarine/Coastal Probabilistic Monitoring Program sampling completed in previous years.

Harmful Algae Bloom (HAB) Monitoring

In 2013, the NRO investigated two reports of algae bloom and collected seven samples following Harmful Algae Bloom (HAB) protocols. There were two sampling events on upper portions of Lake Anna and one in Potomac Creek. In 2014, NRO investigated three reports of algae bloom and collected 5 samples following the HAB protocols. There were sampling events on the hot side of Lake Anna, Potomac Creek and Quantico Creek.

Total Maximum Daily Load Monitoring:

In 2013 and 2014, NRO devoted a significant amount of their monitoring efforts to collecting data for the Total Maximum Daily Load (TMDL) Program. Monitoring was conducted for the purpose of TMDL development and TMDL Implementation Plan follow-up.

TMDL Development Monitoring

In 2013 and 2014, NRO collected ambient monitoring data to support anticipated development of TMDLs to address aquatic life use and recreational use impairments in the following streams: North Fork Catoctin Creek, Jefferies Branch, South Fork Broad Run, Broad Run, Horsepen Run, Indian Creek, Beaverdam Run, Pohick Creek, South Run, Middle Run, Summerduck Run, Northeast Creek and an unnamed tributary to Northeast Creek (at Route 659), Music Branch, Arnolds Creek, Mountain Run, Flat Run, and Jonas Run.

Additionally, NRO collected water and sediment PCBs samples in 2013 and 2014 to support anticipated TMDL development to address fish consumption use impairments in the Mountain Run watershed (RA19) in the vicinity of Culpeper, Virginia.

TMDL Implementation Plan Follow-Up Monitoring

In 2013 and 2014, NRO collected ambient monitoring data as follow-up to TMDL implementation plans developed for the following streams: Thumb Run, Carter Run, Deep Run, Marsh Run watershed (Brown Run, Craig Run and Marsh Run), Hazel River, Catoctin Creek, Upper Hazel, Hughes River, Rush River, Beaver Creek, Mountain Run, Terrys Run, Northeast Creek watershed (Music Branch, Arnolds Creek unnamed tributary to Northeast Creek and Northeast Creek), Pamunkey Creek, Blue Run, Beautiful Run, Rapidan River and unnamed tributaries to the Rapidan River (at Routes 621 and 634), and Wilderness Run.

TMDL Studies:

Development of bacteria TMDLs were initiated in late 2014 in the Mattaponi River Watershed for the following streams: Brock Run, Chapel Creek, Doctors Creek, Glady Run, Maracossic Creek, Mat River, Matta River, Mattaponi River, Motto River, Po River, Polecat Creek, Poni River, Reedy Creek, and Root Swamp. The TMDL study was completed in early 2016 and approved by EPA in July 2016.

Development of sediment and chloride TMDLs are currently under way for the Accotink Creek watershed to address the benthic impairment in the following streams: Upper Accotink Creek (above Lake Accotink), Lower Accotink Creek (below Lake Accotink) and Long Branch. The study began with a stressor analysis, initiated in 2014, which identified chlorides and sediment as the most probable stressors. The TMDL reports are scheduled to be completed Summer 2017.

TMDL Implementation Plan Projects:

Development of an implementation plan for the Upper York River watershed was initiated in 2011 and completed in 2013 for the following streams: Beaver Creek, Goldmine Creek, Mountain Run, Pamunkey Creek, Plentiful Creek and Terrys Run. In the implementation plan development process, major emphasis is placed on discussing best management practices (BMPs), locations of control measures, education, technical assistance, monitoring, and funding.

PIEDMONT REGIONAL OFFICE (PRO)

James River PCB Studies

Due to the presence of PCBs, the VDH has issued a fish consumption advisory for the James River from the I-95 Bridge in Richmond downstream to the Hampton Roads Bridge Tunnel and the tidal portion of the following tributaries: Appomattox River up to Lake Chesdin Dam, Bailey Creek up to Rt. 630, Poythress Run, Bailey Bay, and the Chickahominy River up to Walkers Dam. The advisory recommends that adults do not eat gizzard shad, carp, or blue- and flathead catfish >32 inches long. It also recommends that adults eat no more than two meals/month of blue and flathead catfish <32 inches long, channel catfish, white catfish, largemouth bass, bluegill sunfish, American eel, quillback carpsucker, smallmouth bass, creek chub, yellow bullhead catfish, white perch, striped bass, bluefish, croaker, spot, blueback herring,

and hickory shad.

In preparation for development of the Tidal James River PCB TMDL, DEQ initiated a study of PCBs in ambient water in the James River using a high resolution/low detection method (EPA Method 1668A). During mid-to late 2011, one-time samples were collected at four stations between Hopewell and the Chickahominy River. In addition, monthly samples were collected at the James River near Jordan Point (Rt. 156 bridge station 2-JMS074.44). DEQ also collected PCB samples in multiple watersheds where biosolids had been applied. The data is being used to support development of a model for the James River TMDL.

Mercury Water Column Studies in the Chickahominy, Pamunkey, Mattaponi, Nottoway-, Meherrin-, and Rappahannock Rivers

The Virginia Department of Health issues fish consumption advisories when fish tissue contaminant levels exceed guidelines. (http://www.vdh.virginia.gov/environmental-epidemiology/public-health-toxicology/fish-consumption-advisories/) The fish tissue monitoring program is conducted by the DEQ. The Chickahominy-, Pamunkey, Mattaponi-, Nottoway-, and Meherrin-, and Rappahannock Rivers, among others, are all currently under advisories due to elevated mercury levels. The sources of mercury are considered unknown, but can include atmospheric deposition or industrial discharges. The Piedmont Regional Office has been collecting mercury water column samples in preparation for development of Total Maximum Daily Loads (TMDLs) in those river systems. The sampling is designed to further delineate the extent of the impairments, identify any potential sources or hot spots within the watershed, and quantify levels for future water quality improvement efforts.

Total Maximum Daily Load (TMDL) Studies

During 2009-2016, the Piedmont Regional Office (PRO) completed TMDLs for the following waterbodies:

Chickahominy River and Tributaries - bacterial TMDL
Chickahominy River - benthic (sediment) TMDL
Turkey Island Creek and James River Westover to Claremont Watershed - bacterial TMDL
Pamunkey River and Tributaries - bacterial TMDL
Lower Chickahominy River Watershed - bacterial TMDL (draft)

In addition, PRO is assisting with the development of the Tidal James River PCB TMDL, which is currently under development.

TIDEWATER REGIONAL OFFICE (TRO)

Harmful Algal Blooms Monitoring

The Department of Environmental Quality and the Department of Health, including the Division of Shellfish Sanitation, work together to respond to potentially harmful algal blooms (HABs). Samples from algal blooms and fish kill sites are sent to Old Dominion University and the Virginia Institute of Marine Science for a detailed evaluation for potential harmful algae species. Additional information can be found at http://www.vdh.virginia.gov/environmental-epidemiology/harmful-algal-blooms-habs/.

Coastal 2000 Initiative

The Tidewater Regional Office has been involved with the Coastal 2000 Program as part of the EPA National Coastal Assessments Program. Data has been collected during summer months from 2001 through 2016 at randomly selected sites. For additional information contact the project manager, Dr. Don Smith at donald.smith@deq.virginia.gov.

APPENDIX 1 INTEGRATED LIST OF ALL WATERS

Purpose of the Integrated List

In the 2004 303(d) Impaired Waters Report, Virginia categorized assessed waters in an integrated format for the first time. Virginia has worked closely with the United States Environmental Protection Agency (EPA) to develop an Integrated Report that meets the current EPA assessment guidance and is also representative of the monitoring program and assessment methodology used in Virginia.

The 2016 Integrated List is a general list of all assessed surface waters in Virginia derived from an EPA database known as the Assessment Database (ADB). A description of each of the 2016 assessment categories and sub-categories used in ADB can be found below. They include both EPA-defined categories and Virginia-defined subcategories agreed to by EPA through their review of DEQ guidance for the 2016 water quality assessment. DEQ draft guidance, describing the various assessment methodologies, was released in January 2016, revised in response to EPA and public comment, and finalized in April 2016. The 2016 305(b)/303(d) Water Quality Assessment Guidance Manual can be found on the DEQ water quality website.

The Integrated List uses the highest numbered category that applies to all of the assessed designated uses for a given segment. For instance, if a water is assessed as category 5A for the aquatic life use but attains all other assessed uses, the water is categorized as category 5A. Impaired waters fact sheets provide details about individual segments in Category 5. These fact sheets can be found at the aforementioned website.

Assessed waters in the Virginia 2016 Integrated List were placed in one of the following categories and subcategories:

FULLY SUPPORTING - Waters are supporting one or more designated uses

- **EPA Category 1 -** Attaining all associated designated uses and no designated use is threatened.

  Va. Category 1A - waters are attaining all uses and a TMDL has been developed for one or more uses.

- **EPA Category 2 -** Available data and/or other information indicate that some, but not all of the designated uses are supported.

  Va. Category 2A - waters are supporting all of the uses for which they are monitored.

  Va. Category 2B - waters are of concern to the state but no water quality standard exists for a specific pollutant, or the water exceeds a state screening value or toxicity test.

  Va. Category 2C - waters are now attaining the use(s) for which they were originally 303(d) listed and the TMDL is EPA approved but other applicable use(s) were not monitored and assessed.

INDETERMINATE - Waters needing additional information

- **EPA Category 3 -** Insufficient data and/or information to determine whether any designated uses are met.

  Va. Category 3A - no data are available within the data window of the current assessment to determine if any designated use is attained and the water was not previously listed as impaired.

  Va. Category 3B - some data exists but it is insufficient to determine support of any designated uses. Such waters will be prioritized for follow up monitoring.

Va. Category 3C - data collected by a citizen monitoring or other organization indicate water quality problems may exist but the methodology and/or data quality has not been approved for a determination of support of designated use(s). These waters are considered as having insufficient data with observed effects. Such waters will be prioritized by DEQ for follow up monitoring.

Va. Category 3D - data collected by a citizen monitoring or other organization indicate designated use(s) are being attained but the methodology and/or data quality has not been approved for such a determination.

IMPAIRED - Waters are impaired or threatened but a TMDL is not required

- **EPA Category 4A -** water is impaired or threatened for one or more designated uses but does not require a TMDL because the TMDL for specific pollutant(s) is complete and US EPA approved.

- **EPA Category 4B -** water is impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements (such as VPDES limits under a compliance schedule) are reasonably expected to result in attainment of the water quality standard by the next reporting period or permit cycle.

- **EPA Category 4C -** water is impaired or threatened for one or more designated uses but does not require a TMDL because the impairment is not caused by a pollutant and/or is determined to be caused by natural conditions.

Va. Category 4D - part(s) of a water quality standard is attained for a pollutant with a TMDL, but the remaining criteria for the standard were not assessed due to insufficient information. (Only to be applied to dissolved oxygen in tidal waters of the Chesapeake Bay).

IMPAIRED - Waters are impaired or threatened and require a TMDL

- **EPA Category 5 - Waters are impaired or threatened and a TMDL is needed.**

Va. Category 5A - a water quality standard is not attained. The water is impaired or threatened for one or more designated uses by a pollutant(s) and requires a TMDL (303d list).

Va. Category 5B - the water quality standard for shellfish use is not attained. One or more pollutants causing impairment require TMDL development.

Va. Category 5C - the water quality standard is not attained due to "suspected" natural conditions. The water is impaired for one or more designated uses by a pollutant(s) and may require a TMDL (303d list). Water quality standards for these waters may be re-evaluated due to the presence of natural conditions.

Va. Category 5D - a water quality standard is not attained where TMDLs for a pollutant(s) have been developed, but one or more pollutants are still causing impairment requiring additional TMDL development.

Va. Category 5E - effluent-limited waters receiving discharges from facilities not expected to meet compliance schedules by next permit cycle or reporting period.

Va. Category 5F - the water quality standard is attained for a pollutant(s) with a TMDL and 303(d) delisting approved, but the water remains impaired for additional pollutant(s) requiring TMDL development.

Va. Category 5R - the Water Quality Standard is not attained and the water is impaired, and

implementation of an EPA-approved restoration plan is expected to result in attainment. A status update will be provided each 303(d) cycle to evaluate progress.

- **EPA Category 5M -** waters impaired due to atmospheric mercury.

Potomac and Shenandoah River Basins

Overall Category	305(b) ID	Waterbody Name	Size
1A	VAN-A30R_UMC01A00	Upper Machodoc Creek	2.29 MILES

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

2016 Impaired Waters - 303(d) List

Category 5 - Waters needing Total Maximum Daily Load Study

James River Basin

2016 Impaired Waters - 303(d) List

Category 5 - Waters needing Total Maximum Daily Load Study

James River Basin

Cause Group Code / Impaired Use	Water Name / Cause	Cause Category	Estuary (Sq. Miles)	Reservoir (Acres)	River (Miles)	Initial List Date	TMDL Dev. Priority

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

E26R-04-DO	Browns Creek						
Aquatic Life	Oxygen, Dissolved	5C			2.58	2008	L

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

2016 Impaired Waters - 303(d) List

Category 5 - Waters needing Total Maximum Daily Load Study

Roanoke and Yadkin River Basins

2016 Impaired Waters - 303(d) List

Category 5 - Waters needing Total Maximum Daily Load Study

Roanoke and Yadkin River Basins

Cause Group Code / Impaired Use	Water Name / Cause	Cause Category	Estuary (Sq. Miles)	Reservoir (Acres)	River (Miles)	Initial List Date	TMDL Dev. Priority
M03R-01-TEMP	Johnson Creek						
Aquatic Life	Temperature, water	5C			9.15	2008	L
M03R-02-BAC	Johnson Creek						
Recreation	Escherichia coli	5A			9.15	2014	H

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

Aquatic Life	Oxygen, Dissolved	5A	0.042			2010	L

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

2016 Impaired Waters - 303(d) List

Category 5 - Waters needing Total Maximum Daily Load Study

Chesapeake Bay/Atlantic/Small Coastal Basins

Cause Group Code / Impaired Use	Water Name / Cause	Cause Category	Estuary (Sq. Miles)	Reservoir (Acres)	River (Miles)	Initial List Date	TMDL Dev. Priority

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

2016 Impaired Waters (Category 4A/4D) TMDL Approved and (Category 4B) Other Control Measures Present*

James River Basin

Cause Group Code / Impaired Use	Water Name / Cause	Cause Category	Estuary (Sq. Miles)	Reservoir (Acres)	River (Miles)	Initial List Date	TMDL Dev. Priority

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

2016 Impaired Waters (Category 4A/4D) TMDL Approved and (Category 4B) Other Control Measures Present*

Chesapeake Bay/Atlantic/Small Coastal Basins

Cause Group Code / Impaired Use	Water Name / Cause	Cause Category	Estuary (Sq. Miles)	Reservoir (Acres)	River (Miles)	Initial List Date	TMDL Dev. Priority

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

VA DEQ is transitioning from Fecal Coliform bacteria to Escherichia coli (fresh water) and Enterococci (salt water) for assessing the Recreation Use.

TMDL Development Priorities are: H (High) = formal EPA priority to be addressed with a plan by 2022; M (Medium) = DEQ priority that may be addressed with a plan by 2022; or L (Low) = not prioritized to be addressed with a plan by 2022. Within the H or M priority there may be "2yr" noted which means the priority is to be addressed within the two next years.

Multiple listings are due to the same impairments for different uses and/or different initial listing dates for adjacent waters.

APPENDIX 3 WATERS IDENTIFIED FOR DELISTING SINCE THE 2014 REPORT

Assessment is a process in which impaired and non-impaired waters are systematically identified. This is an iterative process, requiring that waters be investigated on an on-going basis as water quality standards are reviewed/refined, sampling and assessment methods are improved, and management activities are adaptively implemented. Additionally, assessment of water quality must factor in the variability inherent to the natural environment. For instance, poor water quality is often associated with unusually wet weather. A limited dataset for a given water may show violations of water quality standards that are not typical for that water due to unusual weather events, and subsequent monitoring may confirm this. Thus, given the dynamic aspects of both the environment and the assessment process, the revisiting of impaired waters sometimes results in the "delisting" of impairments for 303(d)-listed waters.

There are two types of delistings: partial and full. Waters are listed based on non-attainment of assessed designated uses, with the specific impairments (e.g., dissolved oxygen) broken out individually. A partial delist generally occurs when a water no longer has a specific impairment cause associated with it, but the water is still listed for other impairments. For instance, if a water was originally listed for violations of dissolved oxygen and temperature standards, and recent monitoring indicates that this water is now meeting only dissolved oxygen standards, then the water only qualifies for a partial delisting since the aquatic life use is still not attained. Most delistings are partial. A full delist occurs when a water is no longer impaired. If, in the above example, recent monitoring shows the water meets both dissolved oxygen and temperature standards, then it would qualify for a full delist. In the Assessment Database, partial and full delists are distinguished from each other.

Waters can be delisted for multiple reasons. Changes to assessment protocols can result in delistings, as can changes in water quality standards. Shellfish condemnation zones are developed through modeling of bacteria data and other variables, and the boundaries of these zones often change. The shellfishing use for a water that falls in a condemnation zone in the previous cycle can be delisted if it is no longer included in the zone this cycle. Similarly, data at a new monitoring station may indicate that an impairment, such as dissolved oxygen, has a smaller extent than what was assumed in previous assessments, resulting in delisting of dissolved oxygen for one or more segments. More commonly, analysis of recent station data may show little to no exceedences of water quality standards for parameters previously "failing" at that station. The underlying reasons for improved water quality are frequently unknown. In cases were specific management activities are known to have taken place, such as alterations in dam releases, details are provided in the delist rationale. Bacteria is the most common delisted cause.

The following is the list of water-quality limited waters that have full or partial delists for the 2016 assessment.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAN-A08R_LIV01A00 Little River 6.41 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Benthic Macroinvertebrates - A08R-02-BEN, VAN-A08R-02 (CFL 1998)

During the 2014 cycle, this segment was assessed as not supporting the aquatic life use because biological monitoring events in 2008 (spring and fall) at station 1aLIV004.78 resulted in VSCI scores indicating an impaired macroinvertebrate community. Subsequent biological monitoring events (2) took place in 2013 (spring and fall) 0.01 mile upstream from this location at station 1aLIV004.79. The 2013 events indicated a healthy aquatic community and support of the aquatic life use. The average VSCI score from the two most recent years of sampling also indicates support of the aquatic life use. It has been determined that this segment should be delisted for benthic macroinvertebrates based upon recent VSCI scores indicating a healthy benthic macroinvertebrate community.

VAN-A08R_LIV02B10 Little River 4.36 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Benthic Macroinvertebrates - A08R-03-BEN, VAN-A08R-02 (CFL 2010)

During the 2014 cycle, this segment was assessed as not supporting the aquatic life use because a biological monitoring event in 2008 (fall) at station 1aLIV012.12 resulted in VSCI scores indicating an impaired macroinvertebrate community. Subsequent biological monitoring events (2) took place in 2013 (spring and fall) at this location. The 2013 events indicated a healthy aquatic community and support of the aquatic life use. The average VSCI score from the two most recent years of sampling also indicate support of the aquatic life use. It has been determined that this segment should be delisted for benthic macroinvertebrates based upon recent VSCI scores indicating a healthy benthic macroinvertebrate community.

VAN-A21R_BUL02A00 Bull Run 4.66 Miles Recreation

Delisting Summary:

PARTIAL DELIST 2016 - E. coli - A21R-02-BAC, 60058 (CFL 2006)

During the 2014 cycle, this segment was assessed as not supporting the recreation use because of excursions from the maximum E. coli bacteria criterion (4 of 30 samples - 13.3%) recorded at DEQ's ambient water quality monitoring station 1aBUL025.94 at the Route 705 bridge crossing. Additional bacteria monitoring has been conducted and found that 3 of 32 samples (9.4%) exceed the maximum E. coli bacteria criterion. It has been determined that this segment should be delisted for E. coli based upon an acceptable exceedance rate.

VAN-A24L_OCC01A02 Occoquan Reservoir 1250.03 Acres Aquatic Life

Delisting Summary:

DELIST 2016 - DO - A24L-01-DO (2002)

During each of the biennial cycles from 2002 through 2014, segments VAN-A24L_OCC01A02 and VAN-A24L_OCC02A06 were assessed as not supporting the aquatic life use because excursions from the minimum DO criterion (1130 of 6066 samples - 18.6% in the 2014 cycle) were recorded in pooled samples from all monitoring stations within the segments. Additional monitoring data pooled from all monitoring stations within these segments found that 924 in 9539 samples (9.7%) are less than the minimum DO criterion. It has been determined that these segments should be delisted for DO based upon an acceptable excursion rate.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAN-A24L_OCC02A06 Occoquan Reservoir 63.12 Acres Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - DO - A24L-01-DO (2002)

During each of the biennial cycles from 2002 through 2014, segments VAN-A24L_OCC01A02 and VAN-A24L_OCC02A06 were assessed as not supporting the aquatic life use because excursions from the minimum DO criterion (1130 of 6066 samples - 18.6% in the 2014 cycle) were recorded in pooled samples from all monitoring stations within the segments. Additional monitoring data pooled from all monitoring stations within these segments found that 924 in 9539 samples (9.7%) are less than the minimum DO criterion. It has been determined that these segments should be delisted for DO based upon an acceptable excursion rate.

VAN-A25R_NEA01A00 Neabsco Creek 9.42 Miles Recreation

Delisting Summary:

DELIST 2016 - E. coli - A25R-01-BAC, 00310, VAN-A25R-01 (CFL 2002)

During the 2014 cycle, this segment was assessed as not supporting the recreation use because of excursions from the maximum E. coli bacteria criterion (2 of 11 samples - 18.2%) recorded at DEQ's ambient water quality monitoring station 1aNEA002.89 at the Route 1 (Richmond Highway) bridge. Additional bacteria monitoring at this location found that 0 of 12 samples (0.0%) exceed the maximum E. coli bacteria criterion and additional bacteria monitoring at DEQ's ambient water quality monitoring station 1ANEA007.65 at Darbydale Avenue found that 0 of 12 samples (0.0%) exceed the maximum E. coli bacteria criterion. It has been determined that this segment should be delisted for E. coli based upon an acceptable exceedance rate.

VAN-A30E_UMC04B06 Upper Machodoc Creek 0.4177 Square Miles Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - FECAL COLIFORM 0.1341 sq mi - A30E-03-SF (CFL 2012)

This is a partial delist for shellfishing due to an increase in open shellfish area. In 2014, this segment was categorized as impaired for the shellfishing use due to Section D of the Virginia Department of Health, Division of Shellfish Sanitation, Notice and Description of Shellfish Area Condemnation Number 001A-036, Upper Machodoc Creek, dated 05/15/12. In 2014, this segment was 0.2141 square miles in size. In 2016, approximately 0.1341 square miles of this segment are described as supporting the shellfishing use in the Virginia Department of Health, Division of Shellfish Sanitation, Notice and Description of Shellfish Area Condemnation Number 001A-036, Upper Machodoc Creek, dated May 7, 2013. The remaining portion of this segment that is included in Section D of the Virginia Department of Health, Division of Shellfish Sanitation, Notice and Description of Shellfish Area Condemnation Number 001A-036, Upper Machodoc Creek, dated May 7, 2013, was removed from this segment and was merged with segment VAN-A30E_UMC04C06.

A completed shellfish bacteria TMDL for Upper Machodoc Creek was approved by EPA on 12/18/2008 (36028).

VAP-A31E_MON03B16 Monroe Bay 0.063 Square Miles Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.063 mi2 - A31E-03-SF (CFL 2014)

VDH-DSS Shellfish Condemnation 002-001M2, 9/20/2013

The area was seasonally condemned in the 2010 cycle, however condemnation 002-001A expanded in the 2014 cycle. The Shellfish TMDL for Monroe Creek was approved by the EPA on 6/8/2006 and by the SWCB on 7/27/2009. The area was addressed by the TMDL; therefore, it was considered Category 4A.

Condemnation A shrank slightly in the 2016 cycle and section M2 was split off; it will be considered partially delisted (Cat. 2C.)

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAP-A31R_PIN01A00	Pine Hill Creek Watershed	34.91	Miles	Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - A31R-01-DO / 00908 / 00647 / VAP-A31R-01 (CFL 2002)

During the 2002 cycle, the segment was assessed as impaired of the Aquatic Life use support goals based on DO exceedances at the Route 208 bridge (1APIN000.57). The DO TMDL was due in 2014.

During the 2006 cycle, two Natural Condition studies were performed on Pine Hill Creek. The reports recommended reclassification as Class VII swampwaters.

The Water Quality Standards were revised during the 2010 cycle and Pine Hill Creek was reclassified.

Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence that the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

VAP-A32E_BAN01A00	Barnes Creek	0.0189	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A32E-20-SF (CFL 2014)

Portion of VDH condemnation 004-082D, 1/23/2012

The upper portion of Barnes Creek was assessed as impaired of the Shellfish Use during the 1998 cycle due to a VDH shellfish advisory (082C, 2/10/1997) and was addressed in the TMDL "Chesapeake Bay: Potomac River: Nomini Creek Watershed Total Maximum Daily Load (TMDL) Report for Shellfish Condemnation Areas Listed Due to Bacteria Contamination", which was approved by the EPA on 8/22/2007. This lower portion was listed in the 2014 cycle due to expansion of the Nomini Creek condemnation. It was considered nested in the Barnes Creek TMDL.

During the 2016 cycle, the condemnation shrank and lower Barnes Creek was reopened for harvest (004-082, 1/22/2014); therefore, the segment will be delisted.

VAP-A32E_BUB01A04	Buckner Creek	0.0736	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.0737 mi2 - A32E-05-SF / TMDL 33108 (CFL 1998)

The upper portion of Buckner Creek was assessed as impaired of the Shellfish Use during the 1998 cycle due to VDH shellfish advisory 082D, 2/10/1997. Although the closure was expanded during the 2008 cycle (004-082B 1/27/2006), the 2007 TMDL "Chesapeake Bay: Potomac River: Nomini Creek Watershed Total Maximum Daily Load (TMDL) Report for Shellfish Condemnation Areas Listed Due to Bacteria Contamination" only addressed the original upstream impaired area, which is classified as Category 4A.

However, the impairment expanded during the 2014 cycle due to VDH Shellfish Condemnation 004-082B, 1/25/2010 (see A32E-05-SF2).

In the 2016 cycle, the condemnation shrank (004-082B, 1/22/2014); the condemned area will remain Category 4A and the lower portion will be partially delisted (Category 2C.)

2006 VAP-A32E-05 and 00910 / 2008 A32E-05-SF

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAP-A32E_BUB02B14	Buckner Creek	0.0213	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A32E-05-SF2 (CFL 2014)

VDH Shellfish condemnation 004-082, 1/22/2014 - open

The upper portion of Buckner Creek was assessed as impaired of the Shellfish Use during the 1998 cycle due to VDH shellfish advisory 082D, 2/10/1997. The condemnation expanded during the 2014 cycle (portion of VDH Shellfish Condemnation 004-082B, 1/25/2010). However, the 2007 TMDL "Chesapeake Bay: Potomac River: Nomini Creek Watershed Total Maximum Daily Load (TMDL) Report for Shellfish Condemnation Areas Listed Due to Bacteria Contamination" only addressed the original upstream impaired area, which is classified as Category 4A. The expansion was considered nested in the Buckner Creek TMDL.

During the 2016 cycle, the shellfish condemnation shrank considerably and is now smaller than the 1997 condemnation. The expansion will be delisted.

VAP-A32E_NOM01A04	Nomini Creek, Pierce Creek	0.347	Square Miles	Recreation

Delisting Summary:

PARTIAL DELIST 2016 - Enterococci - A32E-04-BAC (CFL 2014)

During the 2014 cycle, Nomini Creek was impaired of the Recreation Use due to an enterococci exceedance rate of 4/34 at 1ANOM005.99, which is located at the Route 202 bridge.

The bacterial impairment is located within the boundary and tidal excursion of the Nomini Creek Shellfish TMDL, which was approved by the EPA on 8/22/2007 and by the SWCB on 7/31/2008. As the Shellfish Use bacterial WQS is lower than the Recreation Use standard, the impairment was considered nested.

The exceedance rate fell to 3/34 in the 2016 cycle; therefore, the segment will be delisted.

VAP-A32E_NOM01A98	Nomini Creek	0.5404	Square Miles	Recreation

Delisting Summary:

PARTIAL DELIST 2016 - Enterococci - A32E-04-BAC (CFL 2014)

During the 2014 cycle, Nomini Creek was impaired of the Recreation Use due to an enterococci exceedance rate of 4/34 at 1ANOM005.99, which is located at the Route 202 bridge.

The bacterial impairment is located within the boundary and tidal excursion of the Nomini Creek Shellfish TMDL, which was approved by the EPA on 8/22/2007 and by the SWCB on 7/31/2008. As the Shellfish Use bacterial WQS is lower than the Recreation Use standard, the impairment was considered nested.

The exceedance rate fell to 3/34 in the 2016 cycle; therefore, the segment will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAP-A32R_LEC01A10 Lee Creek 1.35 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - A32R-02-DO (CFL 2010)

During the 2010 cycle, Lee Creek was assessed as impaired of the Aquatic Life Use due to dissolved oxygen exceedances at 1ALEC001.18, which is located at the Rt. 675 bridge. The violation rate was 4/13 during the 2012 cycle.

Additional monitoring was conducted during the 2016 cycle. The exceedance rate was 2/20; therefore, the stream will be delisted.

VAP-A32R_NOM02A14 Nomini Creek 3.37 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - pH 3.37 Miles - A32R-06-PH (CFL 2014)

During the 2014 cycle, monitoring occurred throughout the upper Nomini Creek watershed. Multiple tributaries indicated low pH - including Nomini Creek, Marshall Creek, Buena Vista Branch, Oldham Creek, Newtons Mill Run, Antioch Branch, and Templeman Run.

4/5 at 1AANT001.31
3/12 at 1ABUV000.15
2/12 at 1AMAR000.62
2/12 at 1ANET001.77
2/12 at 1AOLD000.70
3/12 at 1ATEM003.54
2/12 at 1ANOM012.38

Note; Nomini Creek, UT (XLK) and Tavern Run were already listed for pH (see A32R-03-PH and A32R-05-PH).

Additional monitoring was conducted during the 2016 cycle at 1ANOM0012.38. The pH exceedance rate was acceptable 2/23 and Nomini Creek will be partially delisted.

VAP-A33E_WES01A06 West Yeocomico River 0.03 Square Miles Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A33E-16-SF (CFL 2012)

VDH-DSS Condemnation 007-028M3, 8/7/2014

The area was impaired in the 2014 cycle due to VDH-DSS Condemnation 007-028D, 10/30/2012. The impairment was considered nested within the West Yeocomico River Shellfish TMDL. The TMDL was included in the Yeocomico River Watershed Shellfish TMDL Report, which was approved by the EPA on 6/8/2006.

During the 2016 cycle, the condemnation converted to seasonally condemned; therefore, the impairment will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAP-A33L_HAM01A12	Hampton Hall, Gardy Millpond	45.86 Acres	Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016- Temperature - A33L-01-TEMP (2014)

During the 2016 cycle an error was discovered from the 2014 cycle. The temperature impairment from 2014 cycle was actually a DO impairment. The violation rate for the DO impairment was 13/69 at station 1AHAM003.08. No new data has been collected since the 2014 cycle. The Temperature was partially delisted during the 2016 cycle due to this error.

VAP-A34E_BOT01A04	Boathouse Creek	0.0671 Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A34E-25-SF / 00930 / VAP-A34E-25 (CFL 2004)

VDH Shellfish Condemnation 008-214D, 2/23/2012 - open 3/10/2014

Boathouse Creek was assessed as not supporting of the Shellfish Consumption Use during the 2008 cycle due to VDH-DSS condemnation 008-214E, 2/17/2005.

During the 2014 cycle, the impairment was considered nested in the Coan River Shellfish TMDL, which was approved by the EPA on 12/18/2003.

Boathouse Creek was open for harvest in 008-214, 3/10/2014; therefore, the impairment will be delisted.

VAP-A34E_BRD01A98	Bridgeman Creek	0.0447 Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A34E-10-SF / 00931 / VAP-A34E-10 / Federal ID 380526 (CFL 1998)

VDH-DSS Condemnation Notice 009-142A, 3/30/2009 - open in 3/24/2014

Bridgeman Creek was included on the 1998 303(d) list due to VDH condemnation 142C, 1/31/1997. The Shellfish TMDL for Bridgeman Creek was developed during the 2010 cycle based on the maximum extent of the impairment (3/17/2008). The TMDL was approved by the EPA on 11/16/2009.

During the 2016 cycle, Bridgeman Creek was open for harvest (009-142, 3/26/2014); therefore, Bridgeman Creek will be delisted (Category 2C).

VAP-A34E_COA01A02	Coan River	0.009 Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A34E-32-SF / 10068 / VAP-A34E-32 / 0069 / VAP-A34E-05 (CFL 2004)

Portion of VDH-DSS Condemnation Notice 008-214B, 2/23/2012 - open 3/10/2014

Headly Cove, Mill Creek and a portion of the Coan River were assessed as impaired of the Shellfish Use in 1998 because of VDH SFC 145H and 145I, 2/25/1997. During the 2004 cycle, the segments expanded and merged. However the 12/18/2003 Coan River Shellfish TMDL report only addressed the original impairments.

The impairment is considered nested within the Coan River Shellfish TMDL, which was approved by the EPA on 12/18/2003.

During the 2016 cycle, condemnation 008-214B, 3/10/2014 shrank considerably and the expansion will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored

Potomac and Shenandoah River Basins

VAP-A34E_COA01B16	Coan River	0.0277	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.0278 mi2 - A34E-05-SF2 / VAP-A34E-05 / 00069 / Federal ID 18429 (CFL 1998)

Portion of VDH-DSS Condemnation Notice 8-214B, 3/10/2016

Mill Creek and the upstream most portion of the Coan River were assessed as impaired of the Shellfish Use in 1998 because of VDH SFC 145I, 2/25/1997. The impairment has expanded in several assessment cycles. However only the original segment was included in "Coan River Watershed Total Maximum Daily Load (TMDL) Report for Six Shellfish Areas", which was completed during the 2006 cycle and approved by the EPA on 12/18/2003 and by the SWCB on 12/02/2004. The segment is classified as Category 4A for shellfish consumption.

During the 2016 cycle, the condemnation shrank significantly and is now smaller than the TMDL extent. The newly opened portion will be partially delisted (0.0284 mi2 Cat 2C).

VAP-A34E_ROG01B16	Rogers Creek	0.0229	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.0229 mi2 - A34E-13-SF / 00942 / VAP-A34E-13 / Federal ID 38023 (CFL 1998)

VDH-DSS Condemnation Notice 009-142C, 3/20/2012 - open 3/26/2014

Rogers Creek was included on the 1998 303(d) list due to VDH condemnation 142B, 1/31/1997. The Shellfish TMDL for Rogers Creek was developed during the 2010 cycle based on the maximum extent of the impairment (3/17/2008). The TMDL was approved by the EPA on 11/16/2009. During the 2016 cycle, the Rogers Creek condemnation shrank. The upstream portion remains impaired (Category 4A); the downstream portion will be partially delisted (Category 2C.)

VAP-A34E_SLO05A98	Little Wicomico River: Slough Creek	0.0324	Square Miles	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - A34E-28-SF / 10064 / VAP-A34E-28 (CFL 2006)

Portion of VDH-DSS Condemnation 010-105M1. 6/9/2014 - seasonally condemned

Slough Creek has been impaired of the Shellfishing Use since the 2006 cycle. In the 2014 cycle, it was impaired due to VDH-DSS Condemnation Notice 010-105E, 5/15/2012. The impairment was considered nested in the nearby Bridge Creek Shellfish TMDL, which was approved by the EPA on 12/18/2003.

However, during the 2016 cycle, the area was opened for harvest (seasonally condemned); therefore, the impairment will be delisted.

VAV-B02R_STC01A00	Strait Creek	3.29	Miles	Recreation

Delisting Summary:

PARTIAL DELIST 2016 - Bacteria - 3.29 Miles - B02R-06-BAC (2006)

This section of Strait Creek was originally listed on the 303(d) list for violating the State's water quality standard for e-coli bacteria during the 2006 assessment period. During the 2006 assessment period 2 of 9 samples (22.22%) at station 1ASTC000.02 violated the State's water quality standard for e-coli bacteria. Data assessed during the 2016 assessment period show 1 violation of 12 samples (8.33%) for e-coli bacteria at station 1ASTC000.02. With this station indicating improvement in water quality below the 10.5% violation rate, the e-coli bacteria impairment on this portion of Strait Creek should be shortened by 3.29 miles and this portion of Strait Creek removed from the 303(d) list. The remaining impairment length is 2.77 miles.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored	

Potomac and Shenandoah River Basins

VAV-B07R_BAB01A00	Babbs Run	11.83 Miles	Recreation	

Delisting Summary:

DELIST 2016 - Bacteria - B07R-01-BAC (2004)

Babbs Run was originally listed on the 303(d) list for violating the State's water quality standard for fecal coliform bacteria during the 2004 assessment period. During the 2004 assessment period 2 of 13 samples (15.38%) at station 1ABAB004.54 violated the State's water quality standard for fecal coliform bacteria. Data assessed during the 2016 assessment period show 0 violations of 12 samples (0.00%) for e-coli bacteria at station 1ABAB004.54. Based on this improvement in water quality below a 10.5% violation rate, Babbs Run should be removed from the 303(d) list.

VAV-B12R_MDL01A00	Middle River	23.15 Miles	Aquatic Life	Recreation

Delisting Summary:

DELIST 2016 - Benthic Macroinvertebrates - B12R-02-BEN (2010)

Middle River was originally listed on the 303(d) list for violating the State's water quality General Standard for benthic macroinvertebrates during the 2010 assessment period. This was based on an impaired benthic status (Virginia Stream Condition Index (VSCI) < 60) at 1BMDL026.58. Data during the 2016 assessment cycle show that station 1BMDL026.58 has improved and the last two monitoring events scored at 64.1 and 67.2 on the Virginia Stream Condition Index. In addition, the upstream station 1BMDL036.08 located in the same assessment unit indicate a fully supporting for VSCI status as well. Based on this improvement in the benthic macroinvertebrate community above the fully supporting VSCI score of 60, the benthic impairment on Middle River should be removed from the 303(d) list.

DELIST 2016 - Bacteria - 26.07 Miles - B15R-01-BAC (2008)

This section of Middle River was originally listed on the 303(d) list for violating the State's water quality standard for e-coli bacteria during the 2008 assessment period. During the 2008 assessment period 2 of 10 samples (20%) at station 1BMDL022.09 violated the State's water quality standard for e-coli bacteria. Data assessed during the 2016 assessment period show 0 violations of 12 samples (0.00%) for e-coli bacteria at station 1BMDL022.09. Additionally, data at an upstream station within the same assessment unit 1BMDL036.08 show 5 violations of 60 samples (8.33%) for e-coli bacteria. With these stations indicating improvement in water quality below the 10.5% violation rate, the e-coli bacteria impairment on this portion of Middle River should be shortened by 26.07 miles and this portion of Middle River removed from the 303(d) list. The remaining impairment length is 17.84 miles.

Data assessed during the 2016 assessment period showed 3 violations of 36 samples (8.33%) of the State's Natural Trout temperature standard at station 1BRSC001.42. Based on this improvement in water quality below a 10.5% violation rate, Roseville Run should be removed from the 303(d) list.

NOTE: Partial delists indicate at least one other pollutant exists on the Assessment Unit (AU). If "PARTIAL" is not specified in the delist statement, the AU is supporting all assessed Uses.

James River Basin

VAP-G01R_XYI01A06 XYI - Coles Run, UT 0.94 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G01R-12-DO / 10094 / VAP-G01R-12 (CFL 2006)

The tributary has been assessed as impaired of the Aquatic Life Use based on a dissolved oxygen exceedance rate of 4/4 at USGS station 0203854210, which is located in the breastworks on the National Battlefield.

Additional data was collected during the 2016 cycle at station 2CXBX001.08. The exceedance rates were acceptable (0/4); therefore, the tributary will be delisted.

VAP-G02E_APP01A12 Appomattox River 0.1127 Square Miles Aquatic Life Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - JMSTFL-DO-BAY / 01782 / VAP-G03E-02 / Federal IDs 40833, 40835, and 40837 (CFL 2006)

The mainstem James River from the Appomattox River to the Chickahominy River was originally listed on the 1998 list as fully supporting but threatened of the Aquatic Life Use goal based on chlorophyll a exceedances. During the 1998 cycle, EPA extended the segment upstream to the fall line and downgraded the river to not supporting of the Aquatic Life Use, citing nutrient concerns.

Several tributaries within the James River system, including tidal Bailey Bay, had previously been listed for dissolved oxygen.

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented.

During the 2016 cycle, the lower tidal freshwater James River estuary passes both of the Open Water Subuse's 30-day mean dissolved oxygen criteria. There is insufficient information to assess the other OW criteria or the Migratory Spawning Use. JMSTFL will be delisted for dissolved oxygen.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it will be considered Category 2C.

VAP-G02R_FOM02A06	Upper Fourmile Creek	9.91	Miles	Aquatic Life	

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G02R-06-DO / 10030 / VAP-G02R-06 (CFL 2006)

During the 2006 cycle, the upstream portion of the Fourmile Creek watershed was considered impaired due to dissolved oxygen exceedance rates of 4/15 at 2-FOM006.87 (Darbytown Road) and 2/12 at 2-XTV001.69 (Strath Road).

No additional data has been collected. However, during the 2010 cycle, the Fourmile Creek watershed was reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-G03R_BLY02A08	Bailey Creek	1.35	Miles	Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G03R-02-DO (CFL 2008)

During the 2008 cycle, monitoring was conducted at 2-BLY003.42, which is located at the Route 156 bridge. The segment of Bailey Creek from Manchester Run to the tidal limit was assessed as impaired of the Aquatic Life Use due to a dissolved oxygen violation rate of 2/14.

The exceedance rate was acceptable during the 2016 cycle (0/14); therefore, the segment will be delisted.

VAP-G03R_GUN01A00	Gunns Run and tributaries	19.75	Miles	Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G03R-01 / 01143 / VAP-G03R-01 (CFL 2002)

In the 2002 cycle, the upper mainstem of Gunns Run was assessed as not supporting of the Aquatic Life Use due to dissolved oxygen exceedances recorded at the Route 618 bridge (2-GUN004.00).

During the 2008 cycle, Gunns Run and its tributaries from the head of tide at river mile 2.64 upstream to its headwaters were recommended for reclassification as Class VII swampwaters. The segment was adjusted to correct the tidal extent and expanded to include the applicable tributaries.

The watershed was reclassified during the 2010 cycle.

Additional monitoring was conducted at 2-GUN004.00 during the 2016 cycle. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-G04E_JMS02A02	James River	20.4085	Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - JMSOH-DO-BAY / VAP-G03E-02 / 10125 / Federal IDs 40824, 40825, and 40826 (CFL 1998)
The mainstem James River from the Appomattox River to the Chickahominy River was originally listed on the 1998 list as fully supporting but threatened of the Aquatic Life Use goal based on chlorophyll_ a exceedances. During the 1998 cycle, EPA extended the impairment upstream to the fall line and downgraded the river to not supporting the Aquatic Life Use, citing nutrient concerns.

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented. The entire Oligohaline James River estuary failed the 30-day Open Water summer dissolved oxygen criteria.

However, during the 2010 cycle, the segment passed all DO criteria which could be assessed. The mainstem James River remained impaired for the Aquatic Life Use due to policy at the time. The tributaries were delisted (partial).

During the 2014 cycle, the JMSOH estuary failed the Open Water 30-day mean summer dissolved oxygen criterion.

JMSOH meets both the summer and rest-of-year 30-day mean dissolved oxygen criteria in the 2016 cycle. There is insufficient information to assess the other dissolved oxygen criteria. The segment will be delisted. The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is Category 2C.

PARTIAL DELIST 2016 - Chlorophyll a - G04E-04-CHLA / Federal ID 40825 (CFL 2008)
The James River from the Appomattox River to the Chickahominy River was originally listed on the 1998 list as fully supporting but threatened of the Aquatic Life Use goal based on chlorophyll a exceedances. During the 1998 cycle, EPA extended the segment upstream to the fall line and downgraded the river to not supporting the Aquatic Life Use, citing nutrient concerns.

A special site-specific chlorophyll standard for the mainstem James River was adopted during the 2008 cycle. The oligohaline segment previously exceeded the spring seasonal mean. However, during the 2016 cycle, JMSOH meets both the spring and summer mean criteria and the segment will be delisted.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is Category 2C.

VAP-G04E_ZZZ01B14	Unsegmented estuaries in G04	0.2308 Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - JMSTFL-DO-BAY / 01782 / VAP-G03E-02 / Federal IDs 40833, 40835, and 40837 (CFL 2006)

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented.

During the 2016 cycle, the lower tidal freshwater James River estuary passes both of the Open Water Subuse's 30-day mean dissolved oxygen criteria. There is insufficient information to assess the other OW criteria or the Migratory Spawning Use. JMSTFL will be delisted for dissolved oxygen.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it will be considered Category 2C.

VAP-G04E_ZZZ01C14	Unsegmented estuaries in G04	0.3479 Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - JMSTFL-DO-BAY / 01782 / VAP-G03E-02 / Federal IDs 40833, 40835, and 40837 (CFL 2006)

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented.

During the 2016 cycle, the lower tidal freshwater James River estuary passes both of the Open Water Subuse's 30-day mean dissolved oxygen criteria. There is insufficient information to assess the other OW criteria or the Migratory Spawning Use. JMSTFL will be delisted for dissolved oxygen.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it will be considered Category 2C.

VAP-G04E_ZZZ02A06	Unsegmented estuaries in G04	0.0001 Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - JMSOH-DO-BAY / Federal IDs 40824, 40825, and 40826 (CFL 2014)

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented. The JMSOH estuary failed the Open Water 30-day mean summer dissolved oxygen criterion in the 2014 cycle.

JMSOH meets both the summer and rest-of-year 30-day mean dissolved oxygen criteria in the 2016 cycle. There is insufficient information to assess the other dissolved oxygen criteria. The segment will be delisted. The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is Category 2C.

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

James River Basin

VAP-G04R_WRD01A00 Wards Creek 8.1 Miles Recreation

Delisting Summary:

DELIST 2016 - E. coli - G04R-01-BAC / 10035 / VAP-G04R-01 (CFL 2006)

During the 2006 cycle, Wards Creek was assessed as not supporting of the Recreation Use support goal based on an E. coli exceedances at monitoring station 2-WRD005.40, which is located at the Route 10 bridge.

The impairment was addressed in the Turkey Island Creek and James River Westover Bacterial TMDL, which was approved by the SWCB on 10/1/2015 and by the EPA on 12/22/2015.

However, the exceedance rate was acceptable during the 2016 cycle (3/35) and the stream will be delisted (Category 2C.)

VAP-G05R_CHK02A04 Chickahominy River 8.27 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G05R-03-DO (CFL 2012)

During the 2012 cycle, the segment of the Chickahominy from the confluence with Stony Run downstream to the Route 360 bridge was assessed as not supporting of the Aquatic Use due to a dissolved oxygen exceedance rate of 2/12 at 2-CHK067.30.

This segment of the river is classified as Class VII swampwater. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the dissolved oxygen impairment has been removed.

VAP-G06R_BEV01A00 Beaverdam Creek 4.97 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - pH 4.97 miles - G06R-06-PH / 01155 / VAP-G06R-06 (CFL 2004)

Beaverdam Creek was previously assessed as not supporting of the Aquatic Life Use based on a pH standard exceedance rate of 3/4 at USGS station 02042433.

During the 2008 cycle, monitoring at DEQ station 2-BEV002.00 at the Route 156 bridge, only slightly upstream of the USGS station, had an acceptable exceedance rate of 0/11; therefore continued monitoring was recommended.

During the 2014 cycle, monitoring was conducted at 2-BEV002.00 as well as 2-BEV-RICH01-NPS, which is a National Park Service station. The NPS station had an acceptable violation rate (0/31), however the DEQ station was 3/26; therefore, the segment remained impaired.

During the 2016 cycle, widespread monitoring was conducted by the DEQ and National Park Service. Although the majority of stations had acceptable pH, the upstream-most station, 2-BEV006.75 continues to have pH exceedances (7/13). The segment will be shortened to end at tributary XBT and the downstream portion will be partially delisted.

James River Basin

VAP-G06R_CHK01A98 Chickahominy River 7.45 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G06R-01-DO / 00447 / VAP-G06R-01N (CFL 1996)

The Chickahominy River has been assessed as not supporting of the Aquatic Life use goal since 1996 due to dissolved oxygen exceedances at the Route 360 bridge (2-CHK062.57) and at the Route 156 bridge (2-CHK055.04).

A Natural Conditions Assessment for DO in the Chickahominy River was conducted during the 2008 cycle. The report recommended that the Chickahominy River from its confluence with Toe Ink Swamp at rivermile 43.07 upstream to the confluence with Stony Run at rivermile 71.03 be reclassified as Class VII swampwater.

The river was reclassified as Class VII swampwater during the 2010 cycle. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-G06R_DER01A04 Deep Run 2.35 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G06R-10-DO / 10122 / VAP-G06R-10 (CFL 2006)

During the 2006 cycle, Deep Run was considered impaired of the Aquatic Life Use due to a dissolved oxygen exceedance rate of 2/15 at 2-DER000.65. No additional data has been collected.

The stream is classified as Class VII. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the dissolved oxygen impairment has been removed.

VAP-G06R_POS01A00 Possum Run 4.86 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - pH - G06R-14-PH (CFL 2008)

During the 2008 cycle, Possum Run was assessed as impaired of the Aquatic Life Use due to a pH violation rate of 2/3 at 2-POS002.62, which is a freshwater probabilistic monitoring station.

Additional monitoring was conducted in the 2016 cycle at station 2-POS000.47, which is located at the Route 609 bridge. The pH exceedance rate was acceptable (1/12); therefore, the segment will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

James River Basin

VAP-G06R_WOS02A02 White Oak Swamp 3.48 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G06R-08-DO / 10040 / VAP-G06R-08 (CFL 2006)

During the 2006 cycle, the segment was considered impaired of the Aquatic Life Use due to dissolved oxygen exceedances at 2-WOS008.15.

The exceedance rates were 2/12 at 2-WOS006.92 and 5/12 at 2-WOS008.15 during the 2010 cycle.

The watershed was reclassified as Class VII swampwaters during the 2010 cycle. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-G06R_WSC01A04 White Oak Swamp Creek 3.81 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G06R-09-DO / 10041 / VAP-G06R-09 (CFL 2006)

During the 2006 cycle, White Oak Swamp Creek was considered impaired of the Aquatic Life Use due to a dissolved oxygen exceedance rate of 2/15 at 2-WSC002.62. No additional data has been collected.

The watershed was reclassified as Class VII swampwaters during the 2010 cycle. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-G06R_XZS01A10 White Oak Swamp, UT 1.44 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G06R-02-DO (CFL 2010)

During the 2010 cycle, the tributary was impaired of the Aquatic Life Use due to a dissolved oxygen exceedance rate of 2/2 at probabilistic monitoring station 2-XZS000.38.

The White Oak Swamp watershed is classified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

James River Basin

VAP-G08E_CHK02A00	Chickahominy River	5.9197	Square Miles	Recreation

Delisting Summary:

PARTIAL DELIST 2016 - Enterococci - G08E-04-BAC / 10098 / VAP-G08E-04 (CFL 2006)

The Chickahominy River below Diascund Creek was initially assessed as not supporting the Recreation Use due to enterococci exceedances at 2-CHK002.17.

During the 2012 cycle, the violation rate was acceptable (1/32). However, the violation rate was 6/46 at 2-CHK006.14 and 3/11 at 2-CHK014.33; therefore, the segment remained listed.

No additional monitoring was collected during the 2014 cycle at 2-CHK014.33. However, exceedance rates at the original listing station 2-CHK002.17 as well as at station 2-CHK006.14 were acceptable (1/35 and 7/69); therefore continued monitoring was recommended.

The Recreation Use was met at all three stations in the 2016 cycle and the Chickahominy River will be delisted.
0/33 at 2-CHK002.17
6/69 at 2-CHK006.14
0/12 at 2-CHK014.33

VAP-G08E_GOR01A06	Gordon Creek	0.2034	Square Miles	Recreation

Delisting Summary:

DELIST 2016 - Enterococci - G08E-05-BAC (CFL 2012)

During the 2012 cycle, tidal Gordon Creek was impaired of the Recreation Use due to an enterococci exceedance rate of 4/33 at 2-GOR000.35.

The exceedance rate was acceptable during the 2016 cycle (2/22); therefore, Gordon Creek will be delisted.

VAP-G08R_MCR01A04	Mill Creek	4.81	Miles	Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - G08R-02-DO / 01166 / VAP-G08R-02 (CFL 2004)

Mill Creek was initially assessed as not supporting of the Aquatic Life use support (ALUS) goal in 2004 based on dissolved oxygen (DO) exceedances at the Route 603 bridge (2-MCR002.38).

During the 2012 cycle, the segment remained impaired for DO with an exceedance rate of 3/14.

The exceedance rate fell to 3/36 in the 2016 cycle and Mill Creek will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

James River Basin

VAP-G08R_MOC01A98 Morris Creek 6.93 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G08R-01 / 00342 / 00343 / VAP-G08R-01 (CFL 1998)

Morris Creek was assessed as not supporting of the Aquatic Life use support (ALUS) goal based on water quality monitoring performed at the Route 623 bridge (2-MOC005.97). The segment was initially listed in 1998.

During the 2008 cycle, additional monitoring was conducted. The impairments were confirmed with the following violation rates:
DO 11/22 at 2-MOC005.97
DO 6/10 at 2-MOC010.97

A Natural Conditions Assessment recommended that Morris Creek and its tributaries from the head of tide at river mile 5.97 upstream to its headwaters be reclassified as Class VII swampwaters. The nontidal watershed above rivermile 5.97 was reclassified during the 2010 cycle. However, it was determined that the tidal limit is actually located at rivermile 6.67; therefore, the original listing station is no longer in this segment. The nontidal Morris Creek is assessed based on stations 2-MOC010.97 and 2-MOC006.67. The dissolved oxygen violation rate was 9/16 at 2-MOC010.97 during the 2010 cycle; therefore, the segment remained Category 4C for DO.

No additional data has been collected. However, per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

VAP-G08R_XAF01A12 XAF - Morris Creek, UT 1.06 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - G08R-03-DO (CFL 2012)

During the 2012 cycle, XAF was assessed as not supporting of the Aquatic Life Use due to a dissolved oxygen exceedance rate of 2/2 at 2CXAF000.46.

However, XAF is classified as a Class VII waterbody in the Virginia Water Quality Standards. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

VAP-G09R_DSC01A00 Diascund Creek 6.88 Miles Recreation

Delisting Summary:

PARTIAL DELIST 2016 - E. coli - G09R-02-BAC (2008)

During the 2008 cycle, Diascund Creek was assessed as not supporting of the Recreation Use due to an E. coli exceedance rate of 4/24 at the Route 628 bridge (2-DSC012.67). The exceedance rate was 3/15 during the 2012 cycle.

However, Diascund Creek met the E. coli criterion during the 2016 cycle (0/12 at 2-DSC012.67). The segment will be delisted.

VAP-G10E_ZZZ01A14	Unsegmented estuaries in G10E	0.0186	Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - JMSOH-DO-BAY / Federal IDs 40824, 40825, and 40826 (CFL 2014)

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented. The JMSOH estuary failed the Open Water 30-day mean summer dissolved oxygen criterion in the 2014 cycle.

JMSOH meets both the summer and rest-of-year 30-day mean dissolved oxygen criteria in the 2016 cycle. There is insufficient information to assess the other dissolved oxygen criteria. The segment will be delisted. The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is Category 2C.

VAP-G10E_ZZZ01B14	Unsegmented estuaries in G10E	0.4843	Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - JMSOH-DO-BAY / Federal IDs 40824, 40825, and 40826 (CFL 2014)

During the 2006 cycle, the Chesapeake Bay water quality standards were implemented. The JMSOH estuary failed the Open Water 30-day mean summer dissolved oxygen criterion in the 2014 cycle.

JMSOH meets both the summer and rest-of-year 30-day mean dissolved oxygen criteria in the 2016 cycle. There is insufficient information to assess the other dissolved oxygen criteria. The segment will be delisted. The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is Category 2C.

VAP-H33R_DCR01A98	Deep Creek	0.37	Miles	Recreation	

Delisting Summary:

PARTIAL DELIST 2016 - E. coli - H33R-02-BAC (CFL 2014)

During the 2014 cycle, the segment was impaired of the Recreation Use due to an E. coli exceedance rate of 2/12 at 2-DRC003.00, which is located on Deep Creek at the Route 684 bridge.

It was nested in the upper James River TMDL in the James River and Tributaries - Lower Piedmont report, which was approved by the EPA on 6/11/2008 and by the SWCB on 4/28/2009.

The exceedance rate was acceptable during the 2016 cycle (2/23); therefore, the impairment will be delisted.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

James River Basin

VAP-H34R_LTP01A04 Little Byrd Creek 8.14 Miles Recreation

Delisting Summary:

DELIST 2016 - E. coli - H34R-02-BAC (CFL 2008)

During the 2008 cycle, Little Byrd Creek was assessed as impaired of the Recreation Use due to E. coli violation rates of 2/11 at the Route 667 bridge (2-LTP002.00) and 4/12 at the Route 610 bridge (2-LTP004.81).

Little Byrd Creek is a tributary of Byrd Creek, which is also impaired due to bacteria. The TMDL for Byrd Creek was approved by the EPA on 6/11/2008 and by the SWCB on 4/28/2009. The TMDL requires a 100% reduction in anthropogenic direct loads, 99% reductions for agriculture, residential and urban loads, and a 71% reduction in wildlife loads; therefore Little Byrd Creek was considered a nested water (Category 4A).

Additional monitoring was conducted during the 2016 cycle. The E. coli exceedance rate was acceptable at station 2-LTP004.81 (1/11); therefore, Little Byrd Creek will be delisted.

VAP-H34R_RSM01A08 Ransome Creek 3.37 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Benthic Macroinvertebrates - H34R-06-BEN (CFL 2008)

During the 2008 cycle, Ransome Creek was assessed as impaired of the Aquatic Life Use due to impairment of the benthic community at 2005 freshwater probabilistic monitoring station (2-RSM001.88).

Further monitoring was conducted at 2-RSM001.88 in 2011 and also at replacement station 2-RSM000.58 during 2011, 2012, and 2014. The benthic community was fully supporting; therefore, Ransome Creek will be delisted.

VAP-H37R_BLG02A08 Big Lickinghole Creek 3.34 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - H37R-03-DO (CFL 2008)

During the 2008 cycle, the upstream segment of Big Lickinghole Creek was assessed as impaired of the Aquatic Life Use due to a dissolved oxygen violation rate of 5/11 at 2-BLG012.33 (the Route 609 bridge).

The exceedance rate was acceptable during the 2016 cycle (0/11); therefore, the segment will be delisted.

James River Basin

VAP-H39R_JMS01A98 James River 7.44 Miles Recreation

Delisting Summary:

PARTIAL DELIST 2016 - E. coli - H39R-26-BAC (CFL 2014)

During the 2014 cycle, the James River between Tuckahoe Creek and William's Island dam was impaired of the Recreation Use due to an E. coli exceedance rate of 4/35 at 2-JMS117.35, which is located at the Huguenot Bridge.

The segment is within the study area for the downstream James River - City of Richmond Bacterial TMDL, which was approved by the EPA on 11/4/2010. The impairment was considered nested (Category 4A.)

The exceedance rate fell to 4/38 in the 2016 cycle; therefore, the segment will be delisted.

VAP-H39R_RDD01A00 Reedy Creek 2.37 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - H39R-06-DO (CFL 2008)

During the 2008 cycle Reedy Creek was assessed as not supporting the Aquatic Life Use due to dissolved oxygen exceedances at the 44th Street bridge and at the Deter Road bridge (2-RDD001.57 and 2-RDD003.61, respectively).

In the 2012 cycle, the violation rates were 3/26 at 2-RDD001.57 and 3/12 at 2-RDD003.61. Dissolved oxygen was acceptable in the lower portion of Reedy Creek (0/27 at 2-RDD000.19 and 0/13 at 2-RDD000.99); therefore, the segment was shortened to end at the tributary above Roanoke Street.

Additional sampling was conducted at 2-RDD001.57 in the 2014 cycle. The DO exceedance rate was acceptable (0/13). However, ACB also conducted monitoring at the same location (2-RDD-RC3-ACB); the violation rate was 2/10. The combined exceedance rate is 2/23 at that location. Although passing, the exceedance rate is marginal and there was no additional monitoring at 2-RDD003.61; therefore, the segment remained impaired for the 2014 cycle but continued monitoring was recommended.

The dissolved oxygen exceedance rate was acceptable at all stations on Reedy Creek in the 2016 cycle; therefore, it will be delisted.
0/25 at 2-RDD000.76
0/23 at 2-RDD-RC1-ACB

James River Basin

VAP-H39R_TKO03A98	Tuckahoe Creek	8.97 Miles	Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen 8.97 mi - H39R-02-DO / 00687 / VAP-H39R-02 (CFL 2006)

There have been widespread dissolved oxygen exceedances on separate segments within the Tuckahoe Creek watershed.

The Tuckahoe Creek Natural Conditions Assessment report was completed in November 2005 to determine the source of the dissolved oxygen impairments. The report recommended delisting Deep Run and Little Tuckahoe Creek, reclassifying Tuckahoe Creek from Little Tuckahoe Creek to its mainstem as Class VII waters due to swamp conditions, and assessing multiple streams within the watershed as Category 4C waters due to natural low flow conditions. A portion of Tuckahoe Creek was delisted in the 2006 cycle due to acceptable dissolved oxygen exceedance rates.

Tuckahoe Creek was reclassified as Class VII swampwaters during the 2010 cycle.

Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed and the Class VII portion of Tuckahoe Creek will be partially delisted in the 2016 cycle.

VAP-H39R_XUT01A04	XUT - Tuckahoe Creek, UT	1.8 Miles	Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen 1.8 mi - H39R-02-DO / 00687 / VAP-H39R-02 (CFL 2006)

There have been widespread dissolved oxygen exceedances on separate segments within the Tuckahoe Creek watershed.

During the 2006 cycle, the tributary was assessed as impaired of the Aquatic Life Use due to a dissolved oxygen violation rate of 3/13 at 2-XUT000.62.

The Tuckahoe Creek Natural Conditions Assessment report was completed in November 2005. The low dissolved oxygen in the segment was attributed to natural low-flow conditions and it was recommended that the segment be assessed Cat. 4C.

Additional field data were collected in the 2016 cycle. The dissolved oxygen exceedance rate was acceptable (1/11); therefore, it will be partially delisted.

DELIST 2016 - pH - H39R-03-PH / 10043 / VAP-H39R-03 (CFL 2006)

During the 2006 cycle, the segment was assessed as impaired of the Aquatic Life Use due to a pH violation rate of 2/13 at 2-XUT000.62.

Additional field data was collected in the 2016 cycle. The pH exceedance rate was acceptable (0/11); therefore, it will be delisted.

VAP-J07R_SQT01A00	Skinquarter Creek	5.29 Miles	Aquatic Life

Delisting Summary:

DELIST 2016-DO-VAP-J07R-01, J07R-01-DO, 00688 (1998)

During the 2016 cycle no new data had been collected. DO violations were documented in this water in 1998. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for site-specific DO criterion, so the DO impairment has been removed.

VAP-J11R_DPC02A00	Deep Creek	5.67 Miles	Aquatic Life	Recreation

Delisting Summary:

DELIST 2016-DO-00690/00041, VAP-J11R-02, J11R-02-DO(1998)

DO violations were documented in this water in 1998. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for site-specific DO criterion, so the DO impairment has been removed.

DELIST 2016-E.coli- VAP-J11R-02, J11R-02-BAC (2010)

During the 2016 cycle the segment was fully supporting for E.coli at station 2-DPC017.07 with a violation rate of 1/12 and at station 2-DPC019.03 with a violation rate of 4/60 and will be delisted.

VAP-J12R_WPK01A98	Winterpock Creek	8.43 Miles	Aquatic Life	

Delisting Summary:

DELIST 2016- DO- 00658/00681, VAP-J12R-02, J12R-02-DO (1994)

During the 2016 cycle new data was collected and DO had a violation rate of 5/12 . DO violations were documented in this water beginning in 1994. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for site-specific DO criterion, so the DO impairment has been removed.

VAP-J12R_WTK02A00	Winticomack Creek	4.07 Miles	Aquatic Life	

Delisting Summary:

Partial Delist 2016-DO- VAP-J12R-01, J12R-01-DO, 00659/00689 (1998)

During the 2016 cycle no new data was collected for DO which has been impaired since 1998. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for site-specific DO criterion.

VAP-J12R_XTZ01A04	UT to Winticomack Creek	2.81 Miles	Aquatic Life	

Delisting Summary:

DELIST 2016- DO-01203/01204, VAP-J12R-04, J12R-04-DO(2004)

During the 2016 cycle no new data was collected for DO which has been impaired since 2004. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for site-specific DO criterion.

The previous Aquatic Life Use is retained as impaired based on EPA action in 1998 to overlist these waters to the 303d listing. Surrogate impairment holder for previous impairment retained due to EPA action. JMSPH meets 30D assessed Bay oxygen criteria, must remain listed as impaired until all Open Water oxygen criteria are assessed. As the impairment is related to the EPA's 1998 303(d) Overlisting, the impairment was attributed to excessive nutrients, the TMDL is due in 2010. 1998 CD segment for nutrients (Attachment A, Category 1, Part 2) VAT-G10E-04. Previous Use ID = VAT-G10E-04. EPA approved Chesapeake Bay TMDL 12/29/2010.

EPA approved Chesapeake Bay TMDL 12/29/2010.

VAT-G15E_JMS01C06	James River - Anderson Park Beach Area	0.0113	Square Miles	Aquatic Life	

Delisting Summary:

PARTIAL DELIST 2016 - BNUT - JMSPH-BNUT-BAY (2010)

Aquatic Life Use is not supporting for the James Polyhaline (JMSPH) Chesapeake Bay Program segment based on summer Chlorophyll-a impairments. Rest-of-year chlorophyll-a data are supporting. Benthics are fully supporting. Summer and rest-of-year 30-day mean dissolved oxygen data are supporting. Submerged aquatic vegetation is supporting based on acreage.

The previous Aquatic Life Use is retained as impaired based on EPA action in 1998 to overlist these waters to the 303d listing. Surrogate impairment holder for previous impairment retained due to EPA action. JMSPH meets 30D assessed Bay oxygen criteria, must remain listed as impaired until all Open Water oxygen criteria are assessed. As the impairment is related to the EPA's 1998 303(d) Overlisting, the impairment was attributed to excessive nutrients, the TMDL is due in 2010. 1998 CD segment for nutrients (Attachment A, Category 1, Part 2) VAT-G10E-04. Previous Use ID = VAT-G10E-04.

The Aquatic Life Use - Summer & ROY is evaluated as meeting the 30 day dissolved oxygen CBP criteria.
EPA approved Chesapeake Bay TMDL 12/29/2010.

VAT-G15E_JMS05A06	James River - Newport News Point to NW Corner Craney Isl.	3.6108	Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - DO - JMSMH-DO-BAY (2006)

Aquatic Life Use is not supporting for the James Mesohaline (JMSMH) Chesapeake Bay Program segment based on Aquatic Vegetation acreage and summer and rest-of-year Chlorophyll-a impairments. Benthics (B-IBI) and summer and rest-of-year 30-day mean dissolved oxygen data are supporting.

1998 CD segment for nutrients (Attachment A, Category 1, Part 2) VAT-G10E-04. Previous Use ID = VAT-G10E-04.

Aquatic Life Use is not supporting for the James Mesohaline (JMSMH) Chesapeake Bay Program segment based on Aquatic Vegetation acreage impairments. Benthics (B-IBI) and summer and rest-of-year 30-day mean dissolved oxygen data are supporting.

EPA approved Chesapeake Bay TMDL 12/29/2010.

VAV-I02R_LTB01A00	Little Back Creek	15	Miles	Aquatic Life

Delisting Summary:

DELIST 2016 - Temperature - I02R-03-TEMP (2012)

Little Back Creek was listed on the 303(d) list for violating the State's water quality standard for temperature during the 2006 assessment period. During the 2006 assessment period 2 violations of 11 samples (18.18%) at station 2-LTB000.01 violated the State's Natural Trout temperature standard. Data assessed during the 2016 assessment period showed 1 violation of 12 samples (8.33%) of the State's Natural Trout temperature standard at station 2-LTB000.01. Based on this improvement in water quality below a 10.5% violation rate, Little Back Creek should be removed from the 303(d) list.

VAV-I05R_CRE01A00	Cedar Creek Lower	1.61	Miles	Aquatic Life

Delisting Summary:

DELIST 2016 - Temperature - I05R-01-TEMP (2006)

Cedar Creek was listed on the 303(d) list for violating the State's water quality standard for temperature during the 2006 assessment period. During the 2006 assessment period 3 violations of 25 samples (12%) at station 2-CRE002.37 violated the State's Natural Trout temperature standard. Data assessed during the 2016 assessment period showed 1 violation of 12 samples (8.33%) of the State's Natural Trout temperature standard at station 2-CRE002.37. Based on this improvement in water quality below a 10.5% violation rate, Cedar Creek should be removed from the 303(d) list.

James River Basin

VAV-I14R_PNR01A02 Panther Run 2.16 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Benthic Macroinvertebrates - I14R-03-BEN (2004)

Panther Run was originally listed on the 303(d) list for violating the State's water quality General Standard for benthic macroinvertebrates during the 2004 assessment period. This was based on an impaired benthic status (USFS MAIS < 13) at station USFS 6018. Data during the 2016 assessment cycle show that station USFS 6018 has improved and the last two monitoring events scored at 68.3 and 70.4 on the Virginia Stream Condition Index. Based on this improvement in the benthic macroinvertebrate community above the fully supporting VSCI score of 60, the benthic impairment on Panther Run should be removed from the 303(d) list.

VAV-I30R_MIT01A02 Mill Creek 2.08 Miles Recreation

Delisting Summary:

DELIST 2016 - Bacteria - I30R-02-BAC (2006)

Mill Creek was originally listed on the 303(d) list for violating the State's water quality standard for fecal coliform bacteria during the 2006 assessment period. During the 2006 assessment period 2 of 12 samples (16.66%) at station 2-MIT000.04 violated the State's water quality standard for fecal coliform bacteria. Data assessed during the 2016 assessment period show 0 violations of 11 samples (0.00%) for e-coli bacteria at station 2-MIT000.04. Based on this improvement in water quality below a 10.5% violation rate, Mill Creek should be removed from the 303(d) list.

VAV-I33R_MRY02A04 Maury River 6.22 Miles Recreation

Delisting Summary:

DELIST 2016 - Bacteria - I33R-02-BAC (2014)

Maury River was listed on the 303(d) list for violating the State's water quality standard for e-coli bacteria during the 2014 assessment period. During the 2014 assessment period 4 of 35 samples (11.43%) at station 2-MRY038.29 violated the State's water quality standard for e-coli bacteria. Data assessed during the 2016 assessment period show 3 violations of 34 samples (8.82%) for e-coli bacteria at station 2-MRY038.29. Based on this improvement in water quality below a 10.5% violation rate, Maury River should be removed from the 303(d) list.

VAV-I36R_ISH01A00 Irish Creek 8.53 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Temperature - I36R-04-TEMP (2010)

Irish Creek was listed on the 303(d) list for violating the State's water quality standard for temperature during the 2010 assessment period. During the 2010 assessment period 2 violations of 11 samples (18.18%) at station 2-ISH000.02 violated the State's Stockable Trout temperature standard. Data assessed during the 2016 assessment period showed 0 violations of 12 samples (0.00%) of the State's Stockable Trout temperature standard at station 2-ISH000.02. Based on this improvement in water quality below a 10.5% violation rate, Irish Creek should be removed from the 303(d) list.

VAW-I10R_POT02A02	Potts Creek	3.98 Miles	Aquatic Life	Recreation

Delisting Summary:

DELIST 2016 - pH - VAW-I10R-01/01691/I10R-01-PH (2004)
The waters are delisted based on data collections at station 2-POT030.66 (Above Rt. 18 Bridge near Campsite). Station 2-POT030.66 2016 IR pH data produce results with no excursions of the pH range of 6.0-9.0 from 12 observations. The 2016 IR reports an exceedance rate of pH at less than 10.5% indicating full support of the Aquatic Life Use.

DELIST 2016 - Bacteria (escherichia coli) - I10R-01-BAC / VAW-I10R-01 / 50262 (2006)
The waters are delisted based on data collections at station 2-POT030.66 (Above Rt. 18 Bridge near Campsite). Station 2-POT030.66 2016 IR escherichia coli (E.coli) data produce results with no excursions of the WQS 235 cfu/100 mL instantaneous criterion from 12 observations. The 2016 IR reports an exceedance rate of E.coli at less than 10.5% indicating full support of the Recreational Use.

VAW-I10R_POT03A02	Potts Creek	5.66 Miles	Aquatic Life	Recreation

Delisting Summary:

PARTIAL DELIST 2016 - pH - VAW-I10R-01/01691/I10R-01-PH (2004)
The waters are delisted based on data collections at station 2-POT030.66 (Above Rt. 18 Bridge near Campsite). Station 2-POT030.66 2016 IR pH data produce results with no excursions of the pH range of 6.0-9.0 from 12 observations. The 2016 IR reports an exceedance rate of pH at less than 10.5% indicating full support of the Aquatic Life Use.

PARTIAL DELIST 2016 - Bacteria (escherichia coli) - I10R-01-BAC / VAW-I10R-01 / 50262 (2006)
The waters are delisted based on data collections at station 2-POT030.66 (Above Rt. 18 Bridge near Campsite). Station 2-POT030.66 2016 IR escherichia coli (E.coli) data produce results with no excursions of the WQS 235 cfu/100 mL instantaneous criterion from 12 observations. The 2016 IR reports an exceedance rate of E.coli at less than 10.5% indicating full support of the Recreational Use.

VAW-I20R_MEO01A00	Meadow Creek	2.59 Miles	Aquatic Life	

Delisting Summary:

DELIST 2016 - Temperature - I20R-01-TEMP (2006)
The waters are delisted based on data collections at station 2-MEO000.38 (Rt. 311 Bridge). Station 2-MEO000.38 2016 IR temperature data produce results with no excursions of the Class VI Water Quality Standard (20°C) out of 12 samples. The 2016 IR reports an exceedance rate of temperature at less than 10.5% indicating full support of the Aquatic Life Use.

VAW-I26R_ELS01A02	Ellis Run	1.69 Miles	Aquatic Life	

Delisting Summary:

PARTIAL DELIST 2016 - Temperature - VAW-I26R-01 / I26R-03-TEMP (2006)
The waters are delisted based on data collections at station 2-ELS000.08 (Rt. 643 Bridge) where only one excursion of the Water Quality Standards Class V 21°C criterion is observed from 12 measurements. The single exceedance is 20.1°C for an exceedance rate of 8.3%.

NOTE: Partial delists indicate at least one other pollutant exists on the Assessment Unit (AU). If "PARTIAL" is not specified in the delist statement, the AU is supporting all assessed Uses.

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored	

Rappahannock River Basin

VAN-E05R_THO03B16	Thornton River	3.12	Miles	Aquatic Life	

Delisting Summary:

DELIST 2016 - Benthic Macroinvertebrates - E05R-01-BEN, VAN-E05R-02 (CFL 2014)

In previous assessments, this 3.12 mile stretch of river was included with the downstream segment (VAN-E05R_THO03A02), which was assessed as not supporting the aquatic life use because biological monitoring in 2008 (fall) at station 3-THO022.27 resulted in a VSCI score indicating an impaired macroinvertebrate community. Subsequent biological monitoring in 2013 and 2014 at stations 3-THO022.27, 3-THO024.12, and 3-THO025.39 indicated that this upstream segment should be split from the downstream impaired segment. Four biological monitoring events in 2013 (spring and fall) and 2014 (spring and fall) at station 3-THO024.12 and four biological monitoring events in 2013 (spring and fall) and 2014 (spring and fall) at station 3-THO025.39 indicated a healthy aquatic community and support of the aquatic life use for this upstream segment that was previously included in assessment unit VAN-E05R_THO03A02. It has been determined that this segment should be delisted for benthic macroinvertebrates based upon recent VSCI scores indicating a healthy benthic macroinvertebrate community.

VAN-E10R_SMR01A04	Sumerduck Run	3.77	Miles	Recreation	

Delisting Summary:

DELIST 2016 - E. coli - E10R-02-BAC, VAN-E10R-02 (CFL 2008)

During the 2014 cycle, this segment was assessed as not supporting the recreation use because of excursions from the maximum E. coli bacteria criterion (2 of 11 samples - 18.2%) recorded at DEQ's ambient water quality monitoring station 3-SMR002.60 at the Route 615 bridge. Additional bacteria monitoring at this location found that 2 of 19 samples (10.5%) exceed the maximum E. coli bacteria criterion. It has been determined that this segment should be delisted for E. coli based upon an acceptable exceedance rate.

VAN-E14R_ROB01A06	Robinson River	3.75	Miles	Recreation	

Delisting Summary:

DELIST 2012 - E. coli - E14R-01-BAC, 60091 (CFL 2006)

During the 2010 cycle, this segment was assessed as not supporting the recreation use because of excursions from the maximum E. coli bacteria criterion (4 of 37 samples - 10.8%) recorded at DEQ's ambient water quality monitoring station 3-ROB017.24 at the Route 638 bridge. Additional bacteria monitoring has been conducted and found that a total of 2 of 28 samples (7.1%) exceed the maximum E. coli bacteria criterion. It has been determined that this segment should be delisted for E. coli based upon an acceptable exceedance rate.

VAN-E18R_RAP03A02	Rapidan River	2.58	Miles	Recreation	

Delisting Summary:

PARTIAL DELIST 2016 - E. coli - E18R-01-BAC (CFL 2002)

During the 2014 cycle, this segment was assessed as not supporting the recreation use because of excursions from the maximum E. coli bacteria criterion (5 of 32 samples - 15.6%) recorded at DEQ's ambient water quality monitoring station 3-RAP006.53 at the Route 610 bridge. Additional bacteria monitoring at this location found that 3 of 33 samples (9.1%) exceed the maximum E. coli bacteria criterion. It has been determined that this segment should be delisted for E. coli based upon an acceptable exceedance rate.

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The mainstem of the Rappahannock River from Myrtle Swamp to its mouth was originally listed in 1998 by DEQ due to dissolved oxygen exceedances and nutrient overenrichment. The EPA extended the segment upstream to the confluence with Totuskey Creek. In the 2004 cycle, dissolved oxygen exceedances were noted in deep water and deep channel stations downstream of the confluence with Lancaster Creek (Morattico), which is further downstream.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

Rappahannock River Basin

VAP-E22R_OCC01B06	Occupacia Creek and tributaries	74.69 Miles	Aquatic Life	

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - E22R-03-DO / 10111 / VAP-E22R-03 (CFL 2006)

The tributaries to Occupacia Creek were first listed for dissolved oxygen in the 2006 cycle. The segment had the following exceedances in the 2008 cycle:
DO 2/18 at 3-BLK002.54
DO 5/18 at 3-BLK006.96
DO 2/18 at 3-XGJ002.23
DO 2/18 at 3-XGJ004.46

The WQS were revised during the 2010 cycle and the Occupacia Creek watershed above its tidal limit was reclassified as Class VII waters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

Rappahannock River Basin

VAP-E23E_PIS02A00	Piscataway Creek	0.5886 Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - pH - E23E-04-PH / 01039 / VAP-E23E-04 (CFL 2002)

The tidal Piscataway Creek was assessed not supporting of the Aquatic Life Use in 2002 based on a pH violation rate of 2/19 at the Route 17 bridge (3-PIS004.79).

The pH TMDL was due in 2014, however a Natural Conditions Assessment was performed on the Piscataway Creek watershed during the 2006 cycle. The report recommends that the creek and its tributaries be reclassified as Class VII swampwaters. The segment was considered Category 4C for pH.

Additional monitoring was conducted during the 2016 cycle. The exceedance rate was acceptable (0/12); therefore, Piscataway Creek will be delisted.

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

Waters Identified for Delisting Since 2014 Report

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

Rappahannock River Basin

VAP-E23R_BLA01A06 Black Swamp 4.18 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - E23R-14-DO / 10105 / VAP-E23R-14 (CFL 2006)

During the 2006 cycle, Black Swamp was assessed as not supporting the Aquatic Life Use based on a dissolved oxygen exceedance rate of 6/15 at 3-BLA002.31, which is located at the Route 644 bridge. The DO exceedance rate was 2/12 at 3-BLA002.31 during the 2014 cycle.

The nontidal Cat Point Creek watershed has been reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

VAP-E23R_MTL01A98 Mount Landing Creek 1.15 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - E23R-02-DO (CFL 2002)

Mount Landing Creek from the Route 716 bridge to the tidal limit at river mile 1.00 was assessed as not supporting of the Aquatic Life use support goal in 1998 based on pH exceedances recorded at monitoring station 3-MTL004.82, located at the Route 716 bridge.

The segment location was changed during the year 2002 cycle because it was determined that the tidal limit is actually located at approximately river mile 4.44 and that the swamp conditions that may cause the impairment extend upstream of the bridge. In addition, the segment was also listed as impaired for dissolved oxygen.

During the 2006 cycle, the "Natural Conditions Assessment for low pH, Mount Landing Creek, Essex, Virginia" recommended that Mount Landing Creek and its tributaries from its headwaters downstream to the head of tide at rivermile 4.44 be reclassified as Class VII swampwater.

The WQS were revised and Mount Landing Creek and its tributaries were reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-E23R_NSS01A12 Nanny Sanford Swamp 3.58 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - E23R-01-DO (CFL 2012)

In the 2012 cycle, Nanny Sanford Swamp was impaired of the Aquatic Life Use due to a dissolved oxygen exceedance rate of 2/12 at 2-NSS000.77, which is located at the Route 622 bridge.

The nontidal Cat Point Creek watershed has been reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

Assessment Unit ID	Waterbody Name	Size	Uses Partially / Fully Restored

Rappahannock River Basin

VAP-E23R_TBS01A06 The Big Swamp 6.74 Miles Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - E23R-15-DO / 10106 / VAP-E23R-15 (CFL 2006)

During the 2006 cycle, The Big Swamp had a dissolved oxygen violation rate of 2/15 at 3-TBS003.39; therefore, the segment was impaired for dissolved oxygen. During the 2014 cycle, the exceedance rate was 4/12 at 3-TBS003.39 and 0/12 (FS) at 3-TBS001.08.

The nontidal Cat Point Creek watershed has been reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed in the 2016 cycle.

VAP-E23R_XFM01A04 UT to Piscataway Creek 3.58 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - E23R-11-DO / 10102 / VAP-E23R-11 (CFL 2006)

During the 2006 cycle, UT XFM was assessed as impaired of the Aquatic Life Use based on a dissolved oxygen exceedance rate of 2/18 at 3-XFM000.82.

During the 2010 cycle, the Piscataway Creek watershed upstream of Sturgeon Swamp was reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen (DO) standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-E23R_XFN01A04 UT to Piscataway Creek 3.61 Miles Aquatic Life

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - E23R-10-DO / 10101 / VAP-E23R-10 (CFL 2006)

During the 2006 cycle, UT XFN was assessed as impaired of the Aquatic Life Use based on a dissolved oxygen violation rate of 2/15 at 3-XFN000.01.

During the 2010 cycle, the Piscataway Creek watershed upstream of Sturgeon Swamp was reclassified as Class VII swampwaters. Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen (DO) standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

VAP-E24E_RPP01B14	Garrett's Marina	0.0026	Square Miles	Aquatic Life	Open-Water Aquatic Life	Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The mainstem of the Rappahannock River from Myrtle Swamp to its mouth was originally listed in 1998 by DEQ due to dissolved oxygen exceedances and nutrient overenrichment. The EPA extended the segment upstream to the confluence with Totuskey Creek. In the 2004 cycle, dissolved oxygen exceedances were noted in deep water and deep channel stations downstream of the confluence with Lancaster Creek (Morattico), which is further downstream.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

PARTIAL DELIST 2016 - Fecal Coliform - E24E-03-SF / Federal ID 39049 (CFL 2014)

Portion of VDH shellfish condemnation 026-181M1, 4/4/2014 - seasonally condemned

Garrett's Marina was impaired of the Shellfish Consumption Use in the 1998 cycle (E24E-03-SF). During the 2008 cycle, the condemnation expanded and incorporated previous condemnation M271, which had been seasonally condemned (observed effects). VDH condemnation 026-181A, 1/20/2006 was rescinded during the 2012 cycle; the area was seasonally condemned and was delisted.

However, a portion of the area was relisted in the 2014 cycle (026-18B, 4/3/2012). The entire area reverted to seasonally condemned again in the 2016 cycle and will be delisted.

Garrett's Marina was included in the Upper Rappahannock Watershed Shellfish TMDL, which was approved by the EPA on 8/10/2010; therefore, this portion is considered Category 2C/2B.

Rappahannock River Basin

VAP-E24E_RPP01C06	Rappahannock River	0.7049	Square Miles	Shellfishing	

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.0613 mi2 - E24E-01-SF / Federal ID 39392 (CFL 2014)

Previous shellfish condemnations have included Totuskey and Richardson Creeks (separately or combined). The streams have been impaired since the 1998 cycle. However, in 2006 the segments, were recombined under 025-071A, 12/22/2004 and extended into the Rappahannock mainstem. The condemnation was further extended in the 2008 cycle per condemnation 024-071A, 10/4/2005.

The Totuskey and Richardson Creeks Bacterial TMDL was approved by the EPA on 2/19/2010. The TMDL was based on the maximum extent of the condemnation, which occurred in condemnation 025-071A, 3/16/2007.

The condemnation was shortened and split in the 2012 cycle and the Rappahannock River was open for harvest; and a portion was partially delisted. It was relisted in the 2014 cycle (VDH-DSS condemnation 4/2/11).. VDH-DSS condemnation 025-071, 3/19/2014 shrank in the 2016 cycle and a portion was delisted again.

The open portion is considered Category 2C.

PARTIAL DELIST 2016 - Enterococci - E25E-11-BAC / 01060 / VAP-E25E-11 (CFL 2004)

In 2004, the segment was assessed as not supporting the Recreation Use due to a fecal coliform violation rate of 2/18 at 3-LAN002.81, located at the end of Route 1105.

During the 2008 cycle, the segment was adjusted to be coincident with the 1995 condemnation. Enterococci monitoring occurred during the 2010 cycle and the impairment converted to enterococci due to a violation rate of 3/12.

As this area was included in the TMDL Report for Shellfish Areas Listed due to Bacterial Contamination for Lancaster Creek, which was approved by the EPA on 8/2/2006 and by the SWCB on 6/27/2007, the enterococci impairment was considered nested. The segment was considered Category 4A for the Recreation Use.

The enterococci exceedance rate was acceptable during the 2016 cycle (1/12); therefore, the impairment will be delisted.

During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

PARTIAL DELIST 2016 - Fecal Coliform 0.0120 mi2 - E25E-13-SF / 01063 / VAP-E25E-13 / Federal ID 25364 (CFL 1998)

Portion of VDH shellfish condemnation 023-121A, 12/31/2014

A portion of Mulberry Creek was included on the 1998 303(d) list due to VDH Shellfish condemnation 120B, 8/14/1995. The TMDL for Shellfish Areas Listed due to Bacterial Contamination for Mulberry Creek was approved by the EPA on 8/2/2006 and by the SWCB on 6/27/2007.

The TMDL only addressed the fecal coliform impairment within the 1998 portion of Mulberry Creek. The segment has shrunk and extended several times. During the 2014 cycle, the condemnation expanded again and was larger than the TMDL area; the expansion was addressed in fact sheet E25E-03-SF. It shrank again during the 2016 cycle and the condemnation is smaller than the original impairment. The closed area remains Category 4C and the opened area will be partially delisted (Category 2C).

During the 2004 cycle, tidal Mud Creek was assessed not supporting of the Aquatic Life Use support goals based on a dissolved oxygen violation rate of 2/2 at 3-MUC002.31.

During the 2006 cycle, it was thought that the station's classification as tidal during the 2004 cycle was a mistake. The impairments were transferred to nontidal Mud Creek.

However, during the 2012 cycle, it was determined that the station is actually tidally influenced. The dissolved oxygen impairment was transferred to RPPMH-DO-BAY.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

PARTIAL DELIST 2016 - Fecal Coliform 0.1646 mi2 - E25E-02-BAC / E25E-02 (CFL 2002)

In 2002, the segment was assessed as not supporting the Recreation Use due to fecal coliform exceedances at the end of Route 680 (3-ROS001.35). The violation rate in the 2004 cycle was 4/20. There has been no additional monitoring since 2001.

The area was addressed in the "Rappahannock River: Lagrange and Robinson Creeks TMDL Report for Shellfish Condemnation Areas Listed due to Bacteria Contamination" which was approved by the EPA on 11/15/2005 and by the SWCB on 9/27/2006. Because the bacteria standard for the Shellfish Use is more stringent than the standard for the Recreation Use, the area was considered nested.

The shellfish condemnation shrank during the 2016 cycle (028-177, 1/24/2014) and a portion will be partially delisted for the Recreation Use to match the shellfish impairment (Category 2A.)

PARTIAL DELIST 2016 - Fecal Coliform 0.0420 mi2 - E25E-02-SF / 00197 / VAP-E25E-02 / Federal ID 25367 (CFL 1998)

The upstream portion of Robinson Creek was assessed in 1998 as not supporting the Shellfish Consumption Use based on VDH-DSS Condemnation 177, 5/28/1997. The TMDL was approved by the EPA on 11/15/2005 and by the SWCB on 9/27/2006. The segment is classified as Category 4A. The condemnation shrank during the 2016 cycle (028-177, 1/24/2014) and a portion will be partially delisted (Category 2C.)

PARTIAL DELIST 2016 - Fecal Coliform 0.0394 mi2 - E25E-22-SF / 10082 / VAP-E25E-22 (CFL 2006)

Described in VDH Shellfish Condemnation 028-177M2, 1/24/2014 - seasonally condemned

The upstream portion of Robinson Creek was assessed in 1998 as not supporting the Shellfish Consumption Use based on VDH-DSS Condemnation 177, 5/28/1997. The TMDL for this original portion has been completed. During the 2006 cycle, however, the condemnation extended downstream. It is considered nested in the upstream Robinson Creek Shellfish TMDL, which was approved by the EPA on 11/15/2005. During the 2016 cycle, a tributary (028-177D, 1/30/2012) was converted to seasonally condemned (028-177M2, 1/24/2014. Therefore, it will be partially delisted.

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The mainstem of the Rappahannock River from Myrtle Swamp to its mouth was originally listed in 1998 by DEQ due to dissolved oxygen exceedances and nutrient overenrichment. The EPA extended the segment upstream to the confluence with Totuskey Creek. In the 2004 cycle, dissolved oxygen exceedances were noted in deep water and deep channel stations downstream of the confluence with Lancaster Creek (Morattico), which is further downstream.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform 0.0018 mi2 - E26E-06-SF / 01080 / VAP-E26E-06 / Federal ID 35562 (CFL 1998)

Ewells Prong was included on the 1998 303(d) list due to VDH condemnation 87A, 4/28/1997. The condemnation subsequently expanded (see 2014 fact sheet E26E-50-SF). The TMDL for the original portion was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008.

Condemnation 021-187B was considerably smaller in the 2016 cycle (10/28/2014) and is now smaller than the TMDL study area. The condemned area is considered Category 4A; the open area will be partially delisted (Category 2C).

VAP-E26E_EWE02A08	Ewells Prong	0.0122	Square Miles	Shellfishing	

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - E26E-50-SF (CFL 2008)

The upstream portion of Ewells Prong was included on the 1998 303(d) list due to VDH condemnation 87A, 4/28/1997. The condemnation has since expanded. The TMDL was completed for the original portion.

In the 2014 cycle, the expansion was included as a portion of VDH Shellfish Condemnation 021-187B, 10/17/2012. It was considered nested in the upstream Ewells Prong Shellfish TMDL, which was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008.

Condemnation 021-187B was considerably smaller in the 2016 cycle (10/28/2014) and is now smaller than the TMDL study area. The expansion will be delisted.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

PARTIAL DELIST 2016 - Fecal Coliform - E26E-32-SF / 01083 / VAP-E26E-32 / Federal ID 35549 (CFL 1998)

Millenbeck Prong was included on the 1998 303(d) list due to VDH condemnation 187B, 4/28/1997. The TMDL was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008.

The condemnation was shortened in the 2010 cycle. The impaired area was considered Category 4A, and the reopened area was partially delisted (Category 2C).

In the 2014 cycle, the condemned area was VDH shellfish condemnation 021-187C, 10/17/2012.

However, during the 2016 cycle, Millenbeck Prong was entirely re-opened to shellfish harvest (021-187, 10/28/2014); therefore, it will be delisted (Category 2C).

Rappahannock River Basin

VAP-E26E_MYE01C04 Myer Creek 0.077 Square Miles Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - E26E-36-SF / 01088 / VAP-E26E-36 (CFL 2004)

A portion of Myer Creek was included on the 1998 303(d) list due to VDH-DSS Condemnation 198, 4/28/1997. The TMDL was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008 (see E26E-05-SF).

A cove of Myer Creek was closed in the 2004 cycle. During the 2012 cycle, it was included in 021-198C, 11/8/2010 (TMDL due in 2014.)

In the 2012 cycle, VDH shellfish condemnation 021-198B, 11/8/2010 grew slightly. The TMDL for the small portion that now extended past the TMDL study area is due in 2024. It was previously addressed in 2012 fact sheet E26E-18-SF.

During the 2014 cycle, condemnation B grew substantially and now incorporated the rest of the 2012 expansion, the cove, and a previously seasonally condemned portion (Portion of VDH Shellfish Condemnation 021-198B, 10/17/2012). The impairments were combined. The area was considered nested within the upstream Myer Creek TMDL; it was considered Category 4A.

During the 2016 cycle, the Myer Creek shellfish condemnation shrank considerably and split. The condemned areas are now smaller than the TMDL study area. This fact sheet addressed the area downstream of the TMDL study area - this is now open for harvest or seasonally condemned (021-198M1, 10/28/2014) and will be delisted.

VAP-E26E_MYE02C16 Myer Creek 0.017 Square Miles Shellfishing

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - E26E-26-SF / 01088 / VAP-E26E-36 (CFL 2004)

A portion of Myer Creek was included on the 1998 303(d) list due to VDH-DSS Condemnation 198, 4/28/1997. The TMDL was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008 (see E26E-05-SF).

A cove of Myer Creek was closed in the 2004 cycle. During the 2012 cycle, it was included in 021-198C, 11/8/2010 (TMDL due in 2014.)

In the 2012 cycle, VDH shellfish condemnation 021-198B, 11/8/2010 grew slightly. The TMDL for the small portion that now extended past the TMDL study area is due in 2024. It was previously addressed in 2012 fact sheet E26E-18-SF.

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The mainstem of the Rappahannock River from Myrtle Swamp to its mouth was originally listed in 1998 by DEQ due to dissolved oxygen exceedances and nutrient overenrichment. The EPA extended the segment upstream to the confluence with Totuskey Creek. In the 2004 cycle, dissolved oxygen exceedances were noted in deep water and deep channel stations downstream of the confluence with Lancaster Creek (Morattico), which is further downstream.

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

Assessment Unit ID	Waterbody Name	Size		Uses Partially / Fully Restored	

Rappahannock River Basin

VAP-E26E_STE01A98	Sturgeon Creek	0.0661	Square Miles	Aquatic Life	Open-Water Aquatic Life

Delisting Summary:

PARTIAL DELIST 2016 - Dissolved Oxygen - RPPMH-DO-BAY / 01776 / VAP-E22E-01 / Federal IDs 40881, 40883, and 40885 (CFL 2014)

The Chesapeake Bay Water Quality Standards were implemented during the 2006 cycle. During the 2014 cycle, the mesohaline portion of the Rappahannock failed the Chesapeake Bay Open Water Subuse's summer 30-day mean dissolved oxygen criterion. Applicable areas also failed the Deep Water 30-day mean dissolved oxygen criteria and the Deep Channel Subuse's instantaneous minimum dissolved oxygen criteria.

In the 2016 cycle, RPPMH passed both Open Water Subuse 30-day mean criteria as well as the Deep Water summer 30-day mean; these areas will be delisted. The Deep Channel Subuse continues to be impaired in applicable areas.

The Chesapeake Bay TMDL was approved by the EPA on 12/29/2010; therefore, it is considered Category 4A/Category 2C as appropriate.

VAP-E26E_TON01A00	Town Creek	0.0165	Square Miles	Shellfishing	

Delisting Summary:

PARTIAL DELIST 2016 - Fecal Coliform - E26E-07-SF (CFL 2014)

During the 2014 cycle, Town Creek was impaired of the Shellfish Consumption Use due to VDH shellfish condemnation 021-187E, 10/17/2012. It was considered nested in the nearby Millenbeck Prong Shellfish TMDL, which was approved by the EPA on 1/23/2008 and by the SWCB on 7/31/2008.

The condemnation was rescinded in the 2016 cycle (021-187, 10/28/2014); therefore, it will be delisted.

VAP-E26R_XEY01A06	UT to Western Branch Corrotoman River	3.27 Miles	Aquatic Life	

Delisting Summary:

DELIST 2016 - Dissolved Oxygen - E26R-02-DO (CFL 2008)

During the 2008 cycle, unnamed tributary XEY was considered impaired of the Aquatic Life Use based on a dissolved oxygen exceedance rate of 5/21 at the Route 604 bridge (3-XEY001.00).

Additional data was collected in the 2016 cycle. The dissolved oxygen exceedance rate was acceptable (0/13); therefore, the stream will be delisted.

DELIST 2016 - pH - E26R-02-PH / 10121 / VAP-E26R-02 (CFL 2006)

During the 2006 cycle, unnamed tributary XEY was considered impaired of the Aquatic Life Use based on pH exceedances at the Route 604 bridge (3-XEY001.00). During the 2008 cycle, the exceedance rate was 5/21.

Additional data was collected in the 2016 cycle. The pH exceedance rate was acceptable (0/13); therefore, the stream will be delisted.

VAW-L06R_BAA01A00	Back Creek	5.68 Miles	Recreation

Delisting Summary:

DELIST 2016 - Bacteria (escherichia coli) - L06R-01-BAC / VAW-L06R-01 / 24538 (2008)
The waters are delisted based on data collections at station 4ABAA000.03 as a replacement station for 4ABAA002.61 (Rt. 660 Bridge - at Gage). The original 2004 303(d) listing station 4ABAA002.61 has since been discontinued due to data collection safety concerns. Station 4ABAA000.03 (Off Rt. 618, Rutrough Road) 2016 IR escherichia coli (E.coli) data produce results with no excursions of the WQS 235 cfu/100 mL instantaneous criterion from 12 observations. This is a 'nested' bacteria impairment within the watershed boundaries of the U.S. EPA approved (8/02/2006 [Fed ID 24538]) Roanoke River Bacteria TMDL with SWCB approval on 9/07/2006. The bacteria (E.coli) 303(d) Listing continued through the 2014 Cycle; a 'nested' Category 4A water.

VAW-L06R_BAA02A00	Back Creek	4.36 Miles	Recreation

Delisting Summary:

DELIST 2016 - Bacteria (escherichia coli) - L06R-01-BAC / VAW-L06R-01 / 24538 (2008)
The waters are delisted based on data collections at station 4ABAA000.03 as a replacement station for 4ABAA002.61 (Rt. 660 Bridge - at Gage). VAW-L43R_SNF02A04	North Fork South Mayo River	2.23 Miles	Aquatic Life

Delisting Summary:

DELIST 2016 - General Standard (Benthic) - VAW-L48R-01 / L43R-01-BEN
The waters are delisted as Virginia Stream Condition Index (VSCI) surveys find full support at station 4ASNF007.64 (Off Rt. 621, Patrick Co.). The VSCI is a multi-metric statewide stream index of biotic integrity that is based on data collected from minimally impacted reference sites throughout Virginia. 4ASNF007.64 was originally listed based on four benthic macroinvertebrate surveys (collected in 2001 and 2002) with an average VSCI score of 57.0. In 2013 and 2014 the same station was sampled to validate the previous assessment and all four samples scored well above 60. Spring and Fall 2013 VSCI Scores were 77.9 and 73.1, respectively. Spring and Fall 2014 VSCI Scores were 69.5 and 65.2, respectively.

VAW-L49R_MTR01A02	Matrimony Creek	4.83 Miles	Recreation

Delisting Summary:

DELIST 2016 - Bacteria - VAW-L48R-01 / L49R-01-BAC (2008)
The waters are delisted based on data collections at station 4AMTR010.33 (Off Rt. 637 Bridge, Henry Co.). Station 4AMTR010.33 2016 IR escherichia coli (E.coli) data produce results with one excursion of the WQS 235 cfu/100 mL instantaneous criterion from 12 observations. This is a 'nested' bacteria impairment within the Dan River Bacteria Total Maximum Daily Load (TMDL) which was U.S. EPA approved on 12/08/2008 [Fed ID 35757] and SWCB approved 4/28/2009. The bacteria (E.coli) 303(d) Listing continued through the 2014 Cycle ('nested' Category 4A water).

NOTE: Partial delists indicate at least one other pollutant exists on the Assessment Unit (AU). If "PARTIAL" is not specified in the delist statement, the AU is supporting all assessed Uses.

Partial Delist 2016-DO- VAP-K10R-02, K10R-06-DO (2010)

During the 2016 cycle the segment was fully supporting for Dissolved Oxygen and will be partially delisted.

VAP-K11R_FON04A00	Fontaine Creek (aka Fountains Creek)	14.48	Miles	Aquatic Life

Delisting Summary:

PARTIAL Delist 2016 -DO-VAP-K09R-01, K11R-02-DO, VAP-K11R-02 (CFL 1998)

DO violations were documented in this water in [1998]. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

Delisting Summary:

DELIST-2016- DO -VAP-K25R-01, K25R-01-DO, 00630/00662(CFL 1998)

DO violations were documented in this water in 1998. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.

VAP-K25R_XFA01A06	UT to Raccoon Creek	4.3	Miles	Aquatic Life

Delisting Summary:

DELIST-2016- DO -VAP-K25R-01, K25R-05-DO, VAP-K25R-0510013(CFL 2006)

DO violations were documented in this water in 2006. It has since been formally re-classified as a swamp water (Class VII). Per Virginia's Water Quality Standards (9VAC25-260-50), numeric dissolved oxygen standards only apply to Class VII waters when there is sufficient evidence the narrative criterion is not protective of aquatic life uses. To date, this Class VII water has not exhibited a need for a site-specific DO criterion, so the DO impairment has been removed.
