ABSTRACT

This document describes the 1991 progress of the Channel Islands National Park Kelp Forest Monitoring Project. Population dynamics of 68 indicator species of algae, fish, and invertebrates were measured at 16 permanent transect sites in 1991 by divers using SCUBA and surface-supply-air. Survey dives were conducted at seven other locations for comparisons and general information. In 1991, nine sites had healthy kelp forests. Five others had some kelp growing on or near the transect, but were dominated somewhat by sea urchins. White sea urchins were present in moderate to high numbers at four sites with declines at two sites and an increase at one. Juvenile fish recruitment was down in 1991; however, young-of-year rockfish were numerous at San Miguel Island and juvenile sheephead and garibaldi were common at Santa Barbara and Anacapa Islands. Abalone recruitment modules proved effective at concentrating juveniles of several species. This year was a poor recruitment year for abalone.

EXECUTIVE SUMMARY

The Channel Islands kelp forests are an important part of southern California's marine ecosystem and economy. Channel Islands National Park has conducted long-term ecological monitoring of the kelp forests around Santa Barbara, Anacapa, Santa Cruz, Santa Rosa and San Miguel islands since 1982. Permanent transects were established at 16 stations between 1981 and 1986. The stations were monitored during eight five-day cruises between June and October. Survey techniques utilizing SCUBA or surface-supply air include; quadrat counts, band transect counts, random point contact quadrat counts, fish transect counts, video transects, photogrammetric plots, size frequency measurements, and species list surveys. The 1991 kelp forest monitoring marks our tenth year of data collection and was completed by 46 National Park Service (NPS) and volunteer divers making over 850 dives.

In 1991, nine of the 16 transects had healthy kelp forests, including all three Anacapa Island sites, Yellow Banks and Gull Island on the south side of Santa Cruz Island, all three Santa Rosa Island sites, and Wyckoff Ledge on the south side of San Miguel Island. Cat Canyon and Arch Point on Santa Barbara Island had some kelp along the transect though the purple sea urchin densities were still high. Kelp grew near

transects at Pelican Bay on Santa Cruz Island, Southeast Sea Lion Rookery on Santa Barbara Island, and Hare Rock San Miguel Island. Hare Rock had the highest density of red sea urchins and Southeast Sea Lion Rookery had the highest density of purple sea urchins. Fry's Harbor on Santa Cruz Island had moderate densities of understory brown algae, primarily southern sea palm, but continued to be dominated by the small aggregated red sea cucumbers. White sea urchins were also common in areas of Fry's Harbor. Scorpion Anchorage on Santa Cruz Island, remains a complete barren with very little algae, a high density of purple sea urchins, and generally low species diversity.

Fewer species of juvenile fish were seen in 1991 than in 1990; however, young-of-the-year and juvenile fish were observed at some sites. Numerous young-of-the-year rockfish were observed in the kelp canopy at Wyckoff Ledge. Juvenile sheephead and garibaldi were abundant at sites on Santa Barbara and Anacapa Islands. Juvenile rockfish and surfperch were abundant at Johnson's Lee North, Santa Rosa Island. Several coldwater species were observed including kelp greenling at San Miguel Island and tubesnouts at Anacapa Island. Tubesnouts were seen spawning at San Miguel Island.

Abalone recruitment modules were built and placed by the Channel Islands Council of Divers at three Anacapa Island sites. This was a cooperative volunteer effort with the National Park Service, California Department of Fish and Game, and Southern California Edison. Red abalone were transplanted to two of the sites. Recruitment modules at Yellowbanks and Gull Island on Santa Cruz Island, and Johnson's Lee North, Santa Rosa Island were monitored for the second year. Few of the original red abalone transplanted in 1990 were found. Survival of the transplants was greatest at Johnson's Lee North.

This year seemed to be a poor recruitment year for abalone. Some young native abalone recruits were found in the recruitment modules, but numbers were low, and in natural habitat where we generally find young abalone, there were few. The modules worked well to attract other young animals and the recommendation is made to use the modules for monitoring size frequencies of sea urchins, sea stars, and possibly other invertebrates.

Sea star wasting disease was observed in bat stars and ochre stars at Gull Island and Fry's Harbor in 1991; however, the severity seemed to be less than in 1990. Juvenile sea stars

were observed at several sites. Young sunflower stars were found at Rodes Reef, Santa Rosa Island and Admiral's Reef, Anacapa Island. Cathedral Cove, Anacapa Island had good recruitment of bat stars and recently settled sea stars were observed on sponges along the north side of Santa Cruz Island.

White sea urchin densities were down overall at Southeast Sea Lion Rookery, Fry's Harbor, Yellow Banks, and Admiral's Reef where they have been most numerous in the past. Southeast Sea Lion was the only site with an increased abundance of white sea urchins. Densities remained unchanged at Fry's Harbor. Large accumulations of fresh white sea urchin tests were observed, most notably at Yellowbanks.

Modifications were made to several of the data management programs to maintain consistency with new hardware used by the park and improve our abilities to present the data. Maintenance of the permanent transects in 1991 included replacing the leadline transects at most stations. Kelp Forest Monitoring Project divers assisted with California Department of Fish and Game abalone surveys in Mendocino and with surveys of Santa Catalina Island for the Channel Islands Research Project.

INTRODUCTION

The waters of Channel Islands National Park and Channel Islands National Marine Sanctuary harbor one-third of southern California's kelp forests (Davies, 1968). The giant kelp, Macrocystis pyrifera is the primary constituent of these kelp forests and over 1,000 species of macro flora and fauna can be found here (Woodhouse 1981, J. M. Engle pers. comm.). Many other species, while not residents of the kelp forest community, are dependent upon the existence and productivity of the kelp forest. The kelp forest serves as food, shelter, substrate and nursery to migratory as well as resident species. Kelp forest detrital flux provides an important source of nutrients to nearby rocky shore, sandy beach and estuary communities. The kelp forests are essential to our commercial and sport fisheries as well as to recreation and the associated tourist industry.

Channel Islands National Park consists of five of the eight California Channel Islands (San Miguel, Santa Rosa, Santa Cruz, Anacapa, and Santa Barbara) and the submerged lands and waters within one nautical mile of each of the islands. The Channel Islands National Marine Sanctuary overlaps the

subtidal portions of the park, and its boundary extends six miles seaward from the park islands. Channel Islands National Park also bears the designation of International Biosphere Reserve and State of California Areas of Special Biological Significance. The State of California maintains jurisdiction over the park's marine resources and manages them through the Department of Fish and Game.

The federal law which established Channel Islands National Park (16-USC-410) directed development of inventories and monitoring of natural resources in the park. Kelp forest monitoring is part of the long-term ecological monitoring at the park designed to measure the health of the ecosystems. By determining the limits of normal variation and diagnosing abnormal conditions we hope to prescribe remedial action through management recommendations.

Following a five year design study begun in 1982, the kelp forest monitoring was implemented in 1987 by the park resource management division, using the protocol established during the design phase. Monitoring design rationale is discussed in Davis and Halvorson (1988). Preliminary results and specific design considerations can be found in reports written by Davis (1985, 1986). Richards, Gramlich, and Davis (1993), describe

monitoring efforts and results for 1982-1989. The 1990 monitoring efforts and results are described in Richards, Avery, and Kushner (1993).

This report summarizes the monitoring efforts and results from 1991, our tenth year of monitoring. It is hoped that these reports will provide some insight into kelp forest dynamics and stimulate further research into the long-term trends and changes in the nearshore ecosystem. We have highlighted some of the most important observations at each of the stations, and tried to provide a characterization for each site. When possible, organisms are referred to by common name and cross referenced to their scientific names in Table 1.

METHODS

Population dynamics of 68 taxa or "target species" (Table 1) were measured at 16 fixed sites (Table 2) around the five park islands (Fig. 1). Site and species selection criteria are provided in the Kelp Forest Monitoring Handbook (Davis, 1988). Sites were monitored between June and October of 1991.

Each site is marked by a 100 m-long transect permanently affixed to the seabed. The sampling techniques employed to

gather population dynamics information are summarized in Table 3. At each station, randomly placed 1 m x 2 m quadrats and 3 m x 20 m band transects were used to determine densities and distribution of discrete benthic organisms; 1000 randomly selected points (RPCs) were used to determine percent cover of encrusting invertebrates, algae, and substrate composition; 2 m x 3 m x 100 m fixed transects were used to determine fish abundance; video taped transects and video taped 20 m^2 photogrammetric plots provide a record of the site appearance; and size frequency measurements were collected to determine age structure, population recruitment, and growth rates. A general species list was made for each station, noting presence/absence and relative abundance for all recognizable species.

In 1991 we decided to terminate size frequencies for the warty sea cucumber and chestnut cowrie. We felt that our sampling excluded juveniles of both species and so the time used for measuring these animals could be better used elsewhere. The video camera was used exclusively for the photoplots in 1991 eliminating the use of still plots. Photoplots were not video taped at Hare Rock, Yellow Banks, and Cat Canyon because the marker-stakes could not be found.

Species checklist	30 - 90 minutes	1 / site

STATION RESULTS AND DISCUSSION

Sampling was completed at all 16 monitoring sites by 46 divers during seven five-day and one four-day cruises plus day trips (Table 5). A total of 844 dives, with 609.5 hours of bottom time, were completed during the regular cruises. An additional 40 dives were made on day trips to monitor abalone recruitment modules.

This year several areas besides the transect sites were surveyed. General observations and species lists were made. A brief description of each site is included with the station summaries below. A summary of the 1991 status of each site is presented in Table 4. A general discussion with recommendations follows. Summary tables for quadrats, band transects, random point contact quadrats (RPCs), fish transects, and size frequencies for all 16 stations can be found in Appendix A. Species lists for the 16 stations are in Appendix B.

Wyckoff Ledge, San Miguel Island

Station #1 SMIWL

1991 sampling dates: 7/23, 7/24, 10/15, 10/16

1991 status: dense kelp forest

There was a very dense kelp canopy over the site in July, with surface canopy at about 100% cover. Kelp coverage on the bottom was 23%. Despite the dense canopy creating a low light condition, red algae on the bottom was very dense (62%) and diverse. Sea tongue covered another 7%. Articulate coralline algae was also abundant at 14%. During the October sampling, the kelp canopy was less dense than it was in July, the color of the kelp was rather pale, and many of the blades were tattered. Bladeless, broken stipes littered the area.

Ornate tube worms were abundant in the sandy areas, dominating 14% of the surface. Bryozoans, sandcastle worms, and sponges were abundant on rocks. The worm Pista elongata and hydroids were the most common miscellaneous invertebrates on RPCs.

Rock crabs were common. Small kelp crabs (Pugettia richii) seemed to be everywhere and were easily seen in their bright red colors. Kelp crabs, Pugettia producta seemed to be more abundant in October compared to July. Mysids, isopods (Idotea resecata), and kelp curler amphipods were common in the kelp canopy. In October, Larvaceans were common in the water column, as were mysids over the sand.

Kellet's whelks were abundant, and the sunflower star was recorded at its highest level on band transects. Purple and red sea urchins were uncommon with densities of $0.1/m^2$ and $0.6/m^2$ respectively.

Large rockfish were common. Juvenile rockfish were abundant. Young-of-the-year rockfish (approximately 1-2 cm) were present in high numbers in the canopy. Schools of tubesnouts were observed and several nests with eggs were found in July, while no nests were found in October. Large lingcod were observed on both visits. In October a kelp greenling was observed, this is the southern limit of its range. A small sample of gut contents revealed that kelp rockfish and olive rockfish have been eating kelp isopods (Idotea resecata) and a copper rockfish had eaten an octopus.

Hare Rock, San Miguel Island

Station #2 SMIHR

1991 sampling dates: 7/22, 7/25, 10/16

1991 status: red sea urchin dominated

Except for some ephemeral algae, the site was mostly barren

and dominated by red sea urchins at a mean of 11/m^2. The red sea urchins had small bodies (58 mm mean size) and long spines that have been associated with poor food conditions. The entire area surrounding the transect was dominated by red sea urchins. Purple sea urchins were present at 2/m^2. In shallow areas, especially near kelp plants, there were some small purple sea urchin aggregations.

There were several acid weed plants growing in the transect area and an occasional patch of red or green algae on rock tops. A few giant kelp plants were growing outside the transect, but they were heavily encrusted with bryozoans and barely reached the surface. Bat stars and giant-spined sea stars were common (2.1 and 1.1/m^2 respectively). One reef south of the transect had a very high density of giant-spined sea stars.

In July, adult and juvenile rockfish were abundant. Sheephead, and both striped and black surfperch were common. In October, Cabezon, scorpion fish, sheephead, schools of blue rockfish, blacksmith, and many juvenile and adult rockfish were noted.

In four dives, only one adult and 20 juvenile red abalone were found in the July sampling along the transects. In October

several dozen red abalone were found inshore from the transect while snorkeling. The abalone were found in depths less than 20 feet deep, mostly in the open, on top of rocks. In shallow areas on Hare Rock at least a dozen more sub-legal red abalone and several black abalone were found.

Clouds of mysids were present near the bottom as they have been for the last few years. In July, two basking sharks were observed just outside Hare rock and later in Cuyler Harbor close to the beach. Swarms of copepods were observed at Hare Rock and were probably the prey of the sharks.

Castle Rock, San Miguel Island. We made survey dives in two areas on the north side of Castle Rock and made species lists. Some red abalone counts and measurements were made. The area was very beautiful with high relief rocky reefs, covered by abundant coralline algae and a mosaic kelp forest with alternating open and dense patches. Large rockfish, perch, sheephead, and lingcod were abundant. Small (100 mm) red abalone were commonly found in holes in the rocks while adults near legal size were out in the open. Large red sea urchins were common. The feather duster worm, Eudistylia polymorpha

were abundant. Two small patches of purple California hydrocoral were found.

Johnson's Lee North, Santa Rosa Island

Station #3, SRIJLNO

1991 sampling dates: 6/12, 8/5, 8/6, 8/7, 10/3

1991 status: dense young kelp forest.

Giant kelp was dense, but many of the plants were young with small holdfast diameters (mean = 23 cm), and low numbers of stipes (mean = 7), most of which just reached the surface so the canopy was not especially thick. Juvenile giant kelp were abundant in patches. Understory algae such as the bladder chain kelp, acid kelp, and California sea palm were abundant in some areas. The brown algae combined gave a 90% cover at the site. Despite all the kelp, miscellaneous red algae and sea tongue combined for a 38% cover.

Bryozoans and tunicates were abundant, together reaching 43% cover. Hydroids (Plumularia sp. and Hydractinia milleri) were the most abundant miscellaneous invertebrates on RPCs. The stalked tunicate was fairly abundant for the third year, appearing in virtually all the quadrats.

Red and purple sea urchin densities were very low, 0.45/m^2 and 0.25/m^2 respectively. The sea urchins were primarily restricted to crevices. Red sea urchin density declined between 1989 and 1990, and in 1991 densities remained a fraction of their 1989 level. It is difficult to say whether this decrease is due to sea urchin harvesting or predation (possibly by the sunflower star which increased 3 fold in 1990, then dropped back off in 1991). Red sea urchins were large with a mean size of 87 and almost 80% being above legal size (75 mm). Giant-spined sea stars were the most numerous sea stars present (0.5/m^2).

Fish diversity was high. Juvenile rockfish and surfperch were the most abundant fish. Kelp surfperch were especially abundant. Kelp surfperch, señoritas, and jack mackerel were observed in large mixed groups feeding among the upper kelp stipes, presumably on the kelp mysids and isopods. The garibaldi nest along the transect was active again this year.

Abalone recruitment was apparently low this year. A considerable effort went into invasive sampling, but turned up no juvenile abalone along the transect. There were 49 red abalone in the 15 recruitment modules, 7 were thought to be

natives. Because of growth on the shell, it was very difficult to distinguish between native and hatchery abalone. The sizes of the abalone ranged from 46-145 mm. The bricks within the habitats were becoming very overgrown, mostly by various bryozoans and sponges. A variety of species were found living in the modules including juvenile rockfish, octopus, juvenile sea stars, sea urchins, a variety of crabs, and other small animals.

Johnson's Lee South, Santa Rosa Island

Station # 4, SRIJLSO

1991 sampling dates: 8/6, 8/7, 10/3

1991 status: healthy, open kelp forest.

This site had a healthy kelp forest, fairly open with a moderate amount of understory algae. Adult and juvenile giant kelp plants were widely spaced, and adult plants were large relative to the Johnson's Lee North site. The density of giant kelp was half that of Johnson's Lee North and the percent cover of kelps was only one-third. Bladder chain and acid kelp were uncommon; however, they were common at the shallower Johnson's Lee North. Miscellaneous red algae covered 33% with another 3% cover for sea tongue.

Small sea cucumbers (Cucumaria sp.) and hydroids (Plumularia sp., and Aglaophenia latirostris) were abundant. Together they were the most numerous miscellaneous invertebrates on RPCs with 30% cover. The ornate tube worm reached 11% cover. Other dominants were bryozoans (15%) and orange cup corals (14%).

Red and purple sea urchin densities decreased to 0.48/m^2 and 1.8/m^2 respectively. Sea urchin density also decreased at the Johnson's Lee North site. Red sea urchins were large here with 61% being legal size or larger and having a mean test diameter of 79 mm.

The red gorgonian was abundant, with most individuals being small. Sunflower stars (0.15/m^2) and bat stars (2.3/m^2) were more common here than at Johnson's Lee North.

Fish species were abundant and diverse. The kelp gunnel and kelp pipefish were observed here, one of the later was caught and measured at 482 mm, near record size. Blue rockfish juveniles were abundant in the transects as were blacksmith. Surfperch, especially rainbow surfperch, were common. Kelp surfperch and the giant kelpfish were abundant in the upper layers of the forest.

Rodes Reef, Santa Rosa Island

Station #5 SRIRR

1991 sampling dates: 7/9, 7/10, 10/2

1991 status: Dense kelp forest

A mature kelp forest with a very dense canopy characterized this site in 1991. Because of a dense canopy in July it was quite dark on the bottom and not surprisingly there were few understory algae. This was reflected in low quadrat counts, low percent cover, and low diversity of algal species. Giant kelp counts were down overall, primarily because of a reduction in juvenile plants. Size frequencies were conducted at the east end of the transect where the plants were no older than one year (the site was damaged in 1990). Holdfasts on plants at the west end of the transect were larger and stipe counts were higher.

During the October sampling we noted a reduced kelp canopy. Many of the canopy blades were pale, torn, and overgrown. Presumably this was a result of the warm waters of late summer. Kelp isopods Idotea resecata and kelp curler amphipods were very common in July and October, and may have been

factors in the shabby appearance of the kelp canopy. Mysid swarms near the bottom were common.

Sponges, tunicates, and bryozoans were both diverse and abundant, together occupying 15% of the substrate. Ornate tube worms were abundant this year with a mean cover of 9%. The southern staghorn bryozoan (5%) and miscellaneous invertebrates (12%) (mostly hydroids and worms) covered another 17% of the substrate. These organisms were also abundant in 1990, and may partially account for the low percent cover of crustose coralline algae.

Purple sea urchins were at low densities (1.3/m^2) and generally only found in deep crevices. Red sea urchins were more dense (2.2/m^2), but at their lowest level ever at this site, again mostly in crevices. Small red sea urchins were commonly found near the large adults.

Bat stars were abundant. Adult and juvenile sunflower stars were also abundant (mode size = 32), even though the band transect counts were low. Blood stars Henricia leviuscula and giant-spined sea stars were common as well.

Large male sheephead were common. Juvenile rockfish and

striped surfperch were abundant. Señorita wrasses were common in the canopy, but not near the bottom. There was a high diversity of fish including tubesnouts, various rockfish, surfperch, and kelp bass.

East Point, Santa Rosa Island

We made survey dives right off the point on a series of rocky reefs at 20 ft, alternating with sand channels about 28 ft deep. The reefs had sparse giant kelp with some dense patches of southern palm kelp. Large specimens of the moon sponge Spheciospongia confoederata were abundant, often with bright yellow Doriopsilla albopunctata nudibranchs or several chestnut cowries on them. The aggregated red sea cucumber, Pachythyone rubra, covered most of the reefs. There was a variety of fish including garibaldi, kelp bass, pile surfperch and white surfperch. The bubble snail Haminoea vesicula was found in abundance in one area.

Talcott Shoals, Santa Rosa Island

This was an interesting area with shale rock reefs. There were

areas of very abundant young recruits of giant kelp. California sea palm dominated in some areas. Boring clams (pholads) were very abundant. Yellow-spot fringeheads were seen in some empty holes. Large mats of small tube worms (Phyllochaetopterous prolifica) were common. Large moon sponges Spheciospongia confoederata, numerous whitecap limpets Acmaea mitra, rough key hole limpets Diodora aspera, and the lined chiton Tonicella lineata were some of the species noted. Schools of rainbow surfperch Hypsurus caryii were also noted.

Gull Island, Santa Cruz Island

Station #6 SCIGI

1991 sampling dates: 5/22, 9/16, 9/17, 10/17

1991 status: Dense, young kelp forest.

There was abundant kelp growing along the entire line. Density and percent cover were the highest recorded here since 1983. The north end of the transect which was mostly bare last May, was covered with juvenile kelp in October. The southern palm kelp appeared stressed, possibly from the dense canopy forming above. Many juvenile southern sea palms were growing along the north end of the transect. In October the giant kelp was healthy with dark color and blades in good shape.

Algae, especially crustose coralline, dominated the site at 50% cover. Bryozoans were the dominant encrusting invertebrates. In the miscellaneous invertebrate category, the Christmas tree worm Spirobranchus spinosus was most common along with a small number of hydroids and spirorbid worms. Together, they covered 13% of the substrate. Bare substrate accounted for only 6%.

Red sea urchin density was at its lowest ever, 0.5/m^2, and purple (16.6/m^2) and white (0.55/m^2) sea urchins continued their downward trend of the past several years. However, the surrounding reef areas were dominated by high densities of purple sea urchins. Red sea urchins were small with a mean size of 28 mm. Several juvenile Coronado sea urchins (Centrostephanus coronatus) were found. Bat stars were common at 1.9/m^2. One bat star was seen exhibiting "wasting disease" symptoms.

Three native red, and no hatchery abalone were found inside the modules. The modules were used for size frequencies of sea stars and sea urchins. Various fish, octopus, snails, sea urchins, and sea stars were found inside the modules.

Small colonies of the purple hydrocoral were observed, indicating good recruitment in recent years. We do not know the age of these 1-2 cm tall colonies.

Fish were abundant and diverse. Large sheephead, cabezon, and lingcod were observed. These are important predators on invertebrates. Rock wrasse were not seen at this site.

Fry's Harbor, Santa Cruz Island

Station #7 SCIFH

1991 sampling dates: 7/10, 7/11, 10/1

1991 status: barren, dominated by aggregated red sea cucumbers.

Divers made surveys both around the point and farther into the cove from the ends of the transect. No giant kelp was observed, however southern sea palm juveniles were common in spots down to 50 feet. There was little other macro algae.

This site continues to be dominated by the aggregated red sea cucumber which completely covered the bottom in some places. Although the total cover was only 16% on RPCs, they appeared to cover a larger area. The aggregated red sea cucumber

abundance increased into the harbor and was most abundant at the mid-level depths (20-40 ft).

White sea urchins were abundant everywhere in the cove below 50 feet. White sea urchins were very abundant on the deeper side of the transect, especially on the south end. The mean number of white sea urchins was only 2.2/m^2, reflecting a patchy distribution. Red and purple sea urchin densities were moderate at 1.6 and 4.8/m^2 respectively. Sea urchins were common outside the cove as were giant-keyhole limpets.

The red gorgonian was very abundant on the lower side of the line. The La Jolla cup coral covered 30% of the substrate. The warty sea cucumber was very abundant at nearly 2/m^2. Chestnut cowries were common.

Bat stars were common at 1.4/m^2, its highest level. Large ochre sea stars and giant-spined sea stars were numerous in the shallow subtidal, feeding on mussels. An ochre sea star was observed exhibiting symptoms of wasting disease.

Blue-banded and blackeye gobies were abundant. There was a high diversity of fish with all target species being found except striped surfperch. Blacksmith were very abundant,

especially juveniles which were very abundant in July. We observed four harbor seals driving mackerel into a cave where they were easier for the seals to catch. Several large kelp bass took advantage of the situation to catch mackerel also.

Pelican Bay, Santa Cruz Island

Station #8 SCIPB

1991 sampling dates 7/8, 7/12, 10/1

1991 status: Barrens

The site was barren; however, there was a fair amount of macro algae including a number of giant kelp plants just outside the transect. The kelp appeared to be healthy and acted as an attractant to fish in the area. A few juvenile giant kelp plants were counted in quadrats, and brown algae (mostly Dictyota binghamiae and Acinetospora nicholsoniae) covered 7% of the transect. Miscellaneous red and green algae (mostly filamentous) together occupied nearly 18% of the substrate. Crustose coralline algae covered nearly 35% of the surface. A diatom film, recorded as miscellaneous plants, grew over much of the coralline algae. There was a lot of silt on the bottom, sometimes over 1 cm deep in rock crevices. The deeper areas often appeared anaerobic just below the surface.

Chaetopterous worms were the most common miscellaneous invertebrate on RPCs (19%). Strawberry anemones and La Jolla cup corals were dominant invertebrates. The California cone snail Conus californica and Nuttall's hornmouth snail Ceratostoma nuttalli were observed laying eggs.

Red and purple sea urchins densities were moderate, 2.2/m^2 and 8.7/m^2 respectively. White sea urchins were not detected in band transects, but were present in deeper areas of Pelican Bay. Wavy top snail densities (0.88/m^2) decreased for its fifth consecutive year.

Both blue-banded and blackeye gobies were abundant. Juvenile sheephead and rock wrasse were common. Large rubberlip surfperch and kelp bass were common. Several kinds of rockfish and two lobster were seen on a night dive in July. Only two lobsters were found despite a lot of searching. Several horn shark egg cases were found among the rocks near the site. Fish in general were abundant in October.

Scorpion Anchorage, Santa Cruz Island

Station #9 SCISA

1991 sampling dates: 9/19, 9/20, 10/4

1991 status: Purple sea urchin barrens

This site was still a complete barren in 1991, showing no signs of recovery since last year. There were no macro brown algae around the site. The only macro algae besides crustose coralline algae (49% cover) were some grazed articulate coralline algae and a few small tufts of Laurencia sp..

The Christmas-tree worm, Spirobranchus spinosus, was the most common miscellaneous invertebrate encountered during the RPCs (12%). Barnacles, tube worms, and small anemones were also present, but made up less than 5% of the miscellaneous invertebrates. Crustose coralline algae covered 50% of the substrate while nearly 32% was recorded as bare substrate.

Purple sea urchins (56.4/m^2) dominated the site. Red sea urchins (0.4/m^2) were sparse and spread out among the boulders. White sea urchins were present but uncommon. Wavy turban snails were abundant (1.1/m^2) in a wide range of sizes, though the mean density was only a quarter of the 1988 mean. Among all the sites this was the highest density of turban snails seen this year.

Yellow banks, Santa Cruz Island

Station #10, SCIYB

1991 sampling dates: 5/29, 8/26, 8/27, 10/17

1991 status: Healthy kelp forest

There was a moderate kelp canopy over the transect site, with what might be described as a typical mature forest; large plants spaced far apart. The kelp forest reestablished itself here in 1988. The California sea palm was quite common along the reef. Bladder-chain kelp was common in patches. While still common in comparison to other stations, brown algae, with the exception of acid-weed, was less common this year than last. The macro algae remained healthy through the summer, not exhibiting a decline as seen at some of the other dense kelp forests. Articulated coralline algae covered 20%, while crustose coralline algae dominated 52% of the substrate on RPCs.

Cup corals and bryozoans were dominant encrusting animals at this site. Hydroids, amphipod tube mats, and the worm Pista elongata were dominants within the miscellaneous invertebrate category on RPCs. Small red gorgonians were common indicating that there was recent recruitment. Mysids and isopods were

scarce in the kelp canopy.

Wavy turban snails were common (0.6/m^2) and generally very large (mean size = 98 mm). Kelp snails, Norrisia norrisi were common in the canopy. The chestnut cowries were observed brooding eggs in the abalone recruitment modules in May.

Red and purple sea urchins were moderately abundant (2.2/m^2 and 11.5/m^2 respectively). White sea urchins were patchy and very abundant in some areas (9/m^2 overall). In October there were a large number of fresh white sea urchin tests along the transect. Sea stars were found in only moderate abundance, with the giant-spined sea star being the most common.

Censusing the 20 abalone recruitment modules yielded 21 abalone; 12 hatchery abalone, 2 red abalone of unsure origin, 4 native reds, and 1 pink abalone. The wire cages on the five modules placed by the Channel Islands Council of Divers were recently changed to the plastic coated wire. Size frequencies of sea stars and sea urchins were partially taken from animals in the modules.

Señorita wrasses and blacksmith were very numerous, especially in October. Sheephead were only moderately abundant.

Northwest Prisoner's Harbor, Santa Cruz Island:

The site was primarily large boulders along a slope similar to Fry's Harbor. There was a slight current, but still a lot of silt. There was some kelp and understory algae, primarily on the large boulders, down to 40 feet. Some pink abalone and several sheep crabs Loxorhyncus grandis were found. The aggregated red sea cucumber Pachythyone rubra were common in some areas, but did not dominate the scene as at Fry's. The intertidal was similar to Fry's with large mussels, huge sea stars, and the green algae, Codium fragile, on which we found an abundance of Elysia hedgpethi, a tiny sea hare.

One-half mile east of Potato Harbor, Santa Cruz Island:

A survey dive was made along the north shore of Santa Cruz Island approximately one-half mile east of Potato Harbor. Enormous mussels and sea stars were on the pinnacles in shallow water. The giant green anemone Anthopleura xanthogramica (not commonly seen east of Santa Rosa) was mixed in with the mussels. Purple sea urchins dominated some of the

shallow areas around the granite boulders. Several bat stars were found that appeared to have wasting disease. Juvenile sea stars (unknown species) were common on red sponges.

Admiral's Reef, Anacapa Island

Station #11 ANIAR

1991 sampling Dates: 7/26, 8/8, 9/18, 9/19

1991 status: Mature kelp forest

Admiral's Reef was characterized by a beautiful mature kelp forest with a rich diversity of life. Four species of gorgonians were found in abundance earning the site its popular name of Coral Reef. Large giant kelp plants were widely spaced, and overall, giant kelp density was low at $0.33/m^2$ with juveniles only making up a third of that. The colander weed, Agarum fimbriatum was quite common and was mostly responsible for the 8% cover by miscellaneous brown algae. Red algae was abundant at this site with 25% cover.

Miscellaneous invertebrates dominated by Christmas-tree worms Spirobranchus spinosus, amphipod tube mats, and a few hydroids, covered 21% of the substrate. There was a broad diversity of encrusting invertebrates at this site with no

dramatic changes in 1991.

White sea urchins were present over much of the reef, but as in previous years, were primarily at the east end of the transect. Overall, white sea urchin densities were the lowest since 1986 (4.9/m^2), and were counted on band transects (in previous years, white sea urchins were counted in quadrats because of their high densities). Red and purple sea urchin densities were moderate, 3.2/m^2 and 7.9/m^2 respectively.

Bat stars were the most common of the monitored sea stars at 0.45/$m^{2,}$ though blood stars Henricia leviuscula and comet stars Linkia columbiana were also common. Warty sea cucumbers were abundant at 1.9/m^2.

Large schools of fish were encountered in the mid and upper canopy. Blacksmith and opaleye were the most abundant. Kelp surfperch and halfmoon were also common. Juvenile and adult giant kelpfish were seen. Several tubesnouts were observed. This fish is not usually seen east of Santa Rosa Island.

Hatchery raised red abalone were placed in the recruitment modules 7/25/91. We measured all the abalone in the modules on 8/8/91, measuring 603 abalone in the seven modules. The

bricks were fairly clean, but there were a number of different invertebrates living among the bricks. Tiny (≈1 cm) sunflower stars were found in at least one module. The wire was rusted and had virtually disintegrated around several modules. Several hatchery abalone were observed living on nearby rocks. Empty shells from the area were collected.

Cathedral Cove, Anacapa Island

Station #12, ANICC

1991 sampling dates: 8/8, 8/29, 8/30

1991 status: Young kelp forest

Giant kelp was growing well along the entire transect. Though the density of kelp on quadrats was low (0.53/m^2), the percent cover from random point counts was 20%. Other algae were scattered, mostly along the deeper side of the transect. Various brown algae were dominant, with red algae being scarce. The boulder area on the shallow side of the transect was primarily barren of algae, with the Christmas-tree worm as the dominant encrusting organism. Thirty-five percent of the of the surface was bare.

Red and purple sea urchins densities were 4.1/m^2 and 0.6/m^2

respectively. Red sea urchins were large with a mean size of 81 mm and 66% were greater than the legal size of 76 mm. Except for juvenile bat stars (mean size of 9 mm) found under rocks, sea stars were uncommon. We should see an increase in bat star densities if these young recruits survive. This was one of the highest concentrations of juvenile bat stars we have seen.

Scallops, pink abalone, and lobster were found in abundance at this site. Both juvenile and adult pink abalone were common. Large lobster were seen, and some dens (including one on a band transect) were packed with lobster. Transparent juvenile lobster were observed here and at night at East Fish Camp, on the south side of Anacapa Island. In a 10 m^2 area, 67 lobster molts were found.

Fish were very abundant at this site. Except for striped surfperch all species on the fish transect were present and juveniles of most species were observed. This year large numbers of juvenile sheephead and garibaldi have been seen at Anacapa and Santa Barbara Islands.

Abalone recruitment modules were placed here during the summer by volunteer divers but were not stocked with transplants. No

native abalone were found inside.

Landing Cove, Anacapa Island

Station #13, ANILC

1991 sampling dates: 8/9, 9/30, 10/18

1991 status: Open kelp forest

This site was characterized by an open kelp forest with little canopy. While there were a number of juvenile giant kelp (1.6/m^2), the overall abundance has remained essentially unchanged over the last four years. The understory kelps, southern sea palm (1.8/m^2), and oar weed (4.6/m^2 and 19% cover) were abundant. The California sea palm was abundant in the deeper section of the transect, but the overall mean from quadrats was low (0.13/m^2). Other algae were present, and agar weed was the most abundant for any site with a mean percent cover of 18%. The dominants within the miscellaneous invertebrate category on random contacts were hydroids and Christmas tree worms.

Both red (3.6/m^2) and purple (3/m^2) sea urchin mean counts increased to their highest levels at this site. All size frequency measurements for sea urchins came from the top of

the reef, so they may not reflect the high percentage of large sized red sea urchins further into the cove. The warty sea cucumber density declined to 0.1/m^2, one-tenth the 1989 count. Juvenile warty sea cucumbers and kellet's whelk were found in the cove.

Pink abalone (0.03/m^2) and rock scallops (0.5/m^2) were common. Wavy turban snails were seen only along the deep part of the transect. Most other macro-invertebrates were present in low numbers. No sea stars were counted in any quadrats or band transects, however, this is not unusual. Only three giant-spined sea stars and one juvenile bat star were found during surveys of the entire site. Large octopi were observed.

Fish diversity was high with opaleye and blacksmith being the most abundant. Garibaldi and kelp bass were also common. Blue-banded gobies were seen but not counted in any of the quadrats. Several juvenile garibaldi were seen throughout the cove. The high numbers and diversity of juvenile fish observed in past years were not seen in 1991.

Garbage Cove, Anacapa Island:

We surveyed Garbage Cove where sea urchin divers had illegally harvested 2500 lbs of red sea urchins, then dumped them in one small area after they were apprehended. Large red sea urchins were abundant all along the slope of the north side of the island. We found an area roughly 25 m^2 that was solid red sea urchins, sometimes two or three deep. There were approximately 300-400 empty tests among the pile where fish had eaten the injured sea urchins. Nearby, there was an area about 1600 m^2 that was nearly cleared of red sea urchins.

Southeast Sea Lion, Santa Barbara Island

Station #14 SBISESL

1991 sampling dates: 6/18, 6/19, 8/28

1991 status: sea urchin barrens

This site was still a sea urchin barrens and remained relatively devoid of large macroalgae. A few giant kelp plants were at the south end of the transect, and several small juvenile kelp plants were found, mostly epiphytic on gorgonians. Thirty-six percent of the substrate was bare. Miscellaneous red algae, mostly filamentous species, reached 8% cover. There were some large patches of Codium setchellii/hubsii, which constituted most of the 3% cover by

green algae. Tunicates and the orange puffball sponge were relatively common, as were large gorgonians, especially the red gorgonian.

Red sea urchins were moderately common at 1.6/m^2. This sea urchin's size frequency distribution exhibited its usual strong bimodality. Purple sea urchin density remained high at 52.7/m^2, but has been declining since 1988. White sea urchins were common at 16.3/m^2.

Warty sea cucumbers, bat stars, and Christmas-tree worms were all observed spawning in June. The giant-spined sea star was observed posturing on the tips of its arms, this may be part of its spawning behavior ritual.

Except for señoritas, blacksmith, and sheephead, fish were not abundant. Juvenile sheephead were observed at all Santa Barbara Island sites. At this site, they were counted on fish transects, and entered in the database as females.

Arch Point, Santa Barbara Island

Station #15 SBIAP

1991 sampling dates: 6/17, 6/18, 8/28

1991 status: sea urchin barren/developing kelp forest

There was approximately 2-3% kelp canopy cover over the transect. The percent cover of kelps on RPCs was recorded at 8%. There were adult giant kelp plants along the south end of line and 20 m north of the transect. Most of these adult plants were small, with a mean number of stipes and holdfast diameter measuring 6 and 11 cm respectively. Numerous small kelp plants ($2/m^2$) were growing on bladder chain kelp, and were noted on quadrat counts as being epiphytic. Articulated coralline algae was the highest abundance seen in many years, with a mean cover of 17%. Agar weed was at its greatest abundance here, covering 2.3% of the substrate.

Many tiny purple sea urchins were seen. Red and purple sea urchin densities remain consistently high at $2.3/m^2$ and $59.5/m^2$ respectively. White sea urchins were not detected in band transect counts, but were present in low numbers.

Chestnut cowries were observed brooding eggs. Giant-spined sea stars were observed eating wavy turban snails. Bat stars were present in low numbers and were absent in quadrats for the third year in a row.

On fish transects, blacksmith, señoritas, garibaldi, and opaleye were common. At least three tagged garibaldi were observed. Tagging was done here in 1984. The island kelpfish was abundant at 0.93/m^2, the highest abundance for all sites.

Cat Canyon, Santa Barbara Island

Station #16 SBICC

1991 sampling dates: 6/19, 6/20, 8/28

1991 status: sea urchin barren

Kelp was present between 70 and 80 meters on the transect and there was a dense patch southeast of the east end. The canopy estimate was 10%, while the percent cover from RPCs was 11%. Juvenile giant kelp plants were very abundant within a few quadrats in the forested area. Otherwise, the site was primarily devoid of macroalgae, with 27% bare rock.

Red sea urchins were common with a density of 1.8/m^2. Purple sea urchins were abundant at 37/m^2, but were the lowest density of the three Santa Barbara Island sites. Bat stars were not detected in quadrat counts, but were present in low numbers. Several green and pink abalone, as well as 19 lobster were found on band transects.

Fish diversity was high with all monitored fish species being found except pile surfperch. Blacksmith and señoritas were abundant.

Seven-tenths Reef, Santa Barbara Island:

This reef is northwest of Webster Point. Some red algae, notably Gigartina corymbifera and numerous painted spindle shells Fusinus luteopictus were found here and not at other sites. The green algae Codium setchellii/hubsii was common also. The scorpion fish Scorpaena guttata were numerous, as were the nudibranchs Dirona picta and Hermissenda crassicornis. On survey dives at Signal Peak, pink abalone were found in patches of five to ten. The old transect line was seen.

Table 4. Kelp forest monitoring site status 1991.

<u>San Miguel Island</u>	
Wyckoff Ledge	Mature kelp forest with dense canopy and abundant understory red algae.
Hare Rock	Sea urchin barren, high density of red sea urchins, strawberry anemones.
<u>Santa Rosa Island</u>	
Johnson's Lee North	Dense young kelp forest.
Johnson's Lee South	Mature open kelp forest.
Rodes Reef	Mature kelp forest with dense canopy and few understory algae.
<u>Santa Cruz Island</u>	
Gull Island South	Dense young kelp forest.
Fry's Harbor	Barrens dominated by aggregated red sea cucumbers and white sea urchins at lower depths.
Pelican Bay	Barrens with moderate density of sea urchins and some brown algae.
Scorpion Anchorage	Sea urchin barren with high density of purple sea urchins and low diversity.
Yellowbanks	Mature open kelp forest with a moderate understory and moderate abundance of white sea urchins.
<u>Anacapa Island</u>	
Admiral's Reef	Mature kelp forest with a rich understory and declining population of white sea urchins.
Cathedral Cove	Open kelp forest with sandy rock barrens.
Landing Cove	Young open kelp forest with a diverse assemblage of fish and invertebrates.
<u>Santa Barbara Island</u>	
SE Sea Lion Rookery	Purple sea urchin barren with a moderate number of white sea urchins.
Arch Point	Purple sea urchin barren with a developing kelp forest.
Cat Canyon	Purple sea urchin barren with some remnant and recovering kelp patches.

GENERAL DISCUSSION

Observing the changes in the kelp forests continues to be an exciting challenge. During the last ten years we have witnessed much change in the kelp forests. Physical factors (storm damage) was responsible for the loss of kelp in some areas, while sea urchins were responsible for the kelp decline in others. Barren areas developed and persisted in some locations and others quickly returned to lush kelp forests. What is apparent, is that there is still much to be understood about this system. The kelp forest ecosystem is dynamic both temporally and spatially. Some trends occur between sites that are similar in relation to depth, exposure, prevailing water temperatures, substrate, and other factors that allow us to make generalizations about broader areas; however, each site is unique with its own attributes. Monitoring more sites would give a better idea of the island chain, but we are limited to only having the time to briefly survey different areas and make general comparisons.

We have also seen dramatic changes occur from year to year. Seasonal sampling would provide insight into the dynamics of those changes (eg. timing of recruitment events, effects of storm waves), but again it is not practical for this program

to provide more than a yearly look at each site. Sampling less than yearly would be very costly in the loss of knowledge about the changes, as we have observed complete changes in the ecosystem within one year.

Juvenile sheephead and garibaldi were both commonly seen at Santa Barbara, Anacapa, and some Santa Cruz Island sites. Increases in the number of sightings this year could be a result of increased recruitment or a late spawning, meaning more young fish still present during the monitoring season. Many of these juvenile fish were one year old which goes along with the general observation that last year was a good recruitment year for many fish.

Nine of the sites (SMIWL, SRIJLNO, SRIJLSO, SRIRR, SCIGI, SCIYB, ANIAR, ANICC, ANILC) had healthy kelp forests this year. Two others (SBICC and SBIAP) had some kelp in the transect area, but were still largely purple sea urchin barrens. Kelp was starting to grow around Pelican Bay, and was present near Hare Rock and Southeast Sea Lion Rookery.

Water temperatures were generally a little cooler on average than last summer. However, the sea star wasting disease which is normally associated with warmer water, was observed again

this year at Gull Island, Fry's Harbor, and east of Potato Harbor. Sea star recruitment was seen in several places this year.

In the spring, new abalone recruitment modules were installed at the three Anacapa sites. This was accomplished with a volunteer effort by the Channel Islands Council of Divers. Red abalone from Channel Islands stock at the California Department of Fish and Game, Granite Canyon Lab were transplanted to the Admiral's Reef modules in July as mentioned above. A transplant of red abalone was made to Landing Cove in December. Modules at Yellow Banks, Gull Island and Johnson's Lee North were censused in May/June and again in August/September.

The abalone recruitment modules do seem to be attracting native abalone; however, it is still too soon to determine if we will be able to detect recruitment pulses with them. Overall abalone recruitment in 1991 seemed to be low. The modules have been interesting to watch as various organisms settle on their surfaces. We believe that the modules will be useful to obtain size frequencies of a variety of organisms and recommend this for future sampling. Other measurements (outside the modules) may be needed to obtain larger animals;

however, the modules seem to work quite well for aggregating small animals and should be useful for detecting recruitment in several species including sea stars and sea urchins. Without the modules it is necessary to turn rocks in order to find juveniles of many species. Juvenile sea stars and sea urchins are especially easy to find in the modules. Juvenile keyhole limpets, chestnut cowries, and warty sea cucumbers which we rarely find even turning rocks, have also been found in a variety of sizes in the modules.

We did not observe any symptoms of the withering foot syndrome among subtidal abalone; however, a giant keyhole limpet Megathura crenulata was collected by park divers off West Anacapa Island that was shrunken and moribund. This was the first and only limpet we have seen with symptoms similar to the intertidal black abalone.

We feel that after ten years it is time to review current techniques in general. One of the advantages of using "volunteer" divers from other agencies and universities is that many new ideas and methods are brought to our attention. New techniques may have been developed that we could apply, or modifications could be made in the sampling or statistical analysis that would give a clearer picture of the community.

To learn about the best and most current sampling techniques, we will continue to consult with other agencies doing similar projects and attend appropriate meetings and symposia. We also propose to conduct a workshop or symposium at a conference with others in the field doing similar monitoring. Goals of such a workshop would be to evaluate our methods and determine if our results are adequately meeting the management needs of the park.

A further recommendation is to update the data management programs for ease of data entry and retrieval. Several modifications were made to existing programs this year and new programs were written to keep up with new hardware at the park. All of this improved our ability to generate data summaries for all the project data. A species list data base needs to be developed to manage data on general species. Some work has been done to create the programs and we are working cooperatively with the Channel Islands Research Program (Tatman Foundation) to develop the database.

This year we looked into using NASA high altitude ER-2 photo imagery as a tool for studying the kelp forests and determining the extent of kelp around the islands. While there seems to be some potential in this, we feel that the

cost is high and that lower altitude images may be more useful to our needs. The need to determine kelp forest canopy cover and integrate the kelp bed locations with a Geographic Information System remains.

Other accomplishments for 1991 included replacing the leadline transects at most of the stations and repairing missing transect and photoplot stakes. This year we spent time with writers from the National Geographic Society, and Backpacker Magazine. Project divers assisted California Department of Fish and Game with abalone surveys in Mendocino County and participated in surveys of Santa Catalina Island for the Tatman Foundation's Channel Island Research Program. Data from the Kelp Forest Monitoring project was used by the California Department of Fish and Game in making recommendations for changes in red abalone management. Data was also requested for defense in a court case involving a sea urchin diver, for use in research on trends analysis by a visiting professor at University of California, Santa Barbara, and for studies on surfperch abundance and juvenile fish recruitment at UCSB.

ACKNOWLEDGEMENTS

This ecological monitoring program was supported by the U.S. National Park Service in cooperation with the California Department of Fish and Game and the U.S. Department of Commerce, National Oceanographic and Atmospheric Administration, Marine Sanctuary Program.

We are deeply indebted to the many divers who have participated in this endeavor. In particular were the sustained efforts of G.E. Davis and M. Conway. R. Walder, S. Pryor, and A. Barberena helped greatly with data entry and checking.

We also appreciate the efforts of D. Richardson, J. Provo, D. Willey, R. Bidwell, and D. Stoltz for supporting us on the boats and keeping us afloat.

Appendix A. 1991 Station Data - All Sampling Methods

Introduction

Following are data gathered in 1991 for all kelp forest monitoring program sampling methods. Means, standard deviations and total number of samples (cases) are given for QUADRATS, BAND TRANSECTS, RANDOM POINT CONTACTS, and FISH TRANSECTS. SIZE FREQUENCY data are presented as percentiles falling within indicated size classes. (Readers should be aware that the number of significant digits is an artifact of the database program and does not imply this level of precision.)

Notes on methods:

QUADRATS. Means represent average counts obtained from 20 stratified random 1m X 2m quadrats, each the sum of two individual divers' counts in 1m X 1m quadrats.

BAND TRANSECTS. Means represent average counts obtained from 12 stratified random 3m X 20m transects, each the sum of two individual divers' counts on 3m X 10m quadrats.

RANDOM POINT CONTACTS. Means represent average percent cover for a given organism, or substrate, at 25 stratified random locations along the transect line. Forty points from each quadrat (1,000 points total) are used to determine percent cover of selected organisms and substrate within one meter of the bottom. Percent cover may total more than 100% because of layering.

FISH TRANSECTS. Means represent the average of counts obtained on each pass by divers swimming the entire 100m transect line and observing fishes passing within a 2m X 3m "window" centered on the line. Cases listed refer to the total number of passes made during fish surveys for the year. Adults and juveniles as well as counts for specific transect pass, date, and time are available as raw data. Horizontal sechi measurements were made on each dive. All counts were conducted between 0900 and 1500 hours.

SIZE FREQUENCY MEASUREMENTS. Cases (N) represent the number of organisms measured. Data are presented as percentiles within size classes. Specific dimensions: Tethya- diameter in mm; Hinnites- maximum shell diameter in mm; Haliotis, and Kelletia- maximum shell length in mm; Astraea- maximum diameter of shell at base in mm; Megathura- shell length, not including mantle, in mm; Sea stars- maximum radius in mm; Sea urchins- test diameter in mm; Macrocystis- number of stipes (counted 1 m above the substrate) and maximum holdfast-base diameters in cm. Gorgonians and Allopora- maximum width and height in cm. Raw data will allow correlation between

stipe number and holdfast diameter for individual kelp plants and between width and height for individual gorgonians.

Appendix B. 1991 Species List for all Channel Islands National Park Kelp Forest Monitoring Stations.

Introduction

The species list contains presence/absence and relative abundance data for all species that could be found during the site visits between June and October. Generally at least one dive is made by an experienced biologist strictly for species list observations. The overall effort varies from station to station with the water conditions and available time. Relative abundance values are subjective, and generally based on opinions of several divers viewing the overall site. Some species assemblages are more difficult to identify than others and may be lumped into general categories. Organism were generally not collected for additional taxonomic work. When identification is tentative we either do not mark it or place a question mark on the list. Some categories, (eg. sponges or tunicates) may be much more diverse than it would appear from the list.

Abundance Ratings

- X - present, no relative abundance rating given
- 4 - abundant, organism present in higher than normal densities
- 3 - common, organism found over most of site or in high density patches
- 2 - present, organism found in moderate numbers
- 1 - rare, few organisms found
- 0 - noticeably absent, an effort was made to look for an organism that was not found.

Notes

- e - eggs
- j or jvs - juvenile
- s - shell only
- int - intertidal
- d - drift
- PM or night - seen only on night dive
- JX - juveniles present and adults present
- J#/# - (e.g. J3/2 - juvenile abundance 3, adult abundance 2)
- nests - hypsypop nest turf
- dis - diseased

Station names are listed in Table 3 of the text.
